N is the 14th letter in our alphabet. It was also the 14th letter in the alphabet used by the Semitic peoples, who once lived in Syria and Palestine. Its symbol apparently came from the Egyptian hieroglyphic (picture symbol) for snake. Later Western Semitic traditions called this letter nun, which was the word for fish. The Greeks took over the letter from the Phoenicians and called it nu. See Alphabet.

Uses. N or n is about the fifth most frequently used letter in books, newspapers, and other printed material in English. In mathematics, n represents an indefinite number. As an abbreviation, n may stand for noun, neuter, noon, name, or not N. In chemical formulas, means nitrogen; in geographic descriptions, north or northern.

In medieval Roman numerals, N represented 90 and \( \overline{N} \), 90,000.

Pronunciation. In English, a person pronounces n by placing the tip of the tongue against the gums behind the front teeth and making the sound through the nose. In such words as hymn, the final n is silent. But in such words as gnostic or mnemonic, the first n is pronounced, and the letter before it is silent. Double n, in words such as manner, is pronounced like n. In words like pen-name, each n is pronounced. The letter has much the same sound in classical Greek and Latin, and in French and German. In Spanish, when written with a tilde, \( \tilde{n} \), it has a ny sound, as in the English word canyon. See Pronunciation. Marianne Cooley

Development of the letter N

The ancient Egyptians drew this symbol of a snake about 3000 B.C.

The Semites, about 1500 B.C., wrote the letter in this form.

The Phoenicians simplified the Semitic symbol about 1000 B.C.

The Greeks changed the letter and added it to their alphabet about 600 B.C. They called it nu.

The Romans, about A.D. 114, wrote the letter N with straight lines.

The small letter n developed about A.D. 500 from Roman writing. Monks who copied manuscripts modified the letter during the 800's. By about 1500, the n had its present shape.

Special ways of expressing the letter N

- International Morse Code
- Braille
- International Flag Code
- Semaphore Code
- Sign Language Alphabet

Common forms of the letter N

Handwritten letters vary from person to person. Manuscript (printed) letters, left, have simple curves and straight lines. Cursive letters, right, have flowing lines.

Roman letters have small finishing strokes called serifs that extend from the main strokes. The type face shown above is Baskerville. The italic form appears at the right.

Sans-serif letters are also called gothic letters. They have no serifs. The type face shown above is called Futura. The italic form of Futura appears at the right.

Computer letters have special shapes. Computers can "read" these letters either optically or by means of the magnetic ink with which the letters may be printed.
NAACP. See National Association for the Advancement of Colored People.

Nabokov, NAH bah kawf, Vladimir, VLAH dah meer (1899-1977), was a Russian-born author. His novels are noted for their complicated plots and the complex attitudes they express toward their subjects. Critics praised Nabokov's novels for their wit, intricate word use, and rich language. His novels, often satirical, include Invitation to a Beheading (published in the Soviet Union, 1938; United States, 1959), The Real Life of Sebastian Knight (1941), Lolita (published in France, 1953; United States, 1958), Pnin (1957), Pale Fire (1962), and Ada (1969). Nabokov published collections of stories and poetry and translated several Russian literary classics into English. Speak, Memory (1951, expanded 1966) is his autobiography. A collection of his lectures at Cornell University in the 1950's was published as Lectures on Literature (1980). The Stories of Vladimir Nabokov was published in 1995.

Nabokov was born in St. Petersburg. The family fled to Western Europe in 1919 because of the Bolshevik revolution. Nabokov attended Cambridge University in England from 1919 to 1922. From 1922 to 1940, he lived in Berlin and Paris among other Russians who had left their country because of the revolution. He wrote his novels in Russian, and most were later translated into English. In 1940, Nabokov settled in the United States and began to write in English. He returned to Europe to live in 1959. Marcus Klein

Nabrit, James Madison, Jr. (1900-1997), won fame as a lawyer, university president, and diplomat. From 1960 to 1969, he was president of Howard University. He was the first black to become deputy U.S. representative to the United Nations (UN). He held the post in 1966 and 1967, while on leave from Howard.

Nabrit was born in Atlanta, Georgia. He graduated from Morehouse College and Northwestern University Law School. In 1936, he joined the faculty of Howard University. At his suggestion, the university established—and he taught—the first civil rights course in an American law school. Nabrit served as secretary of the university from 1939 to 1960, and as dean of its law school from 1958 to 1960. As president of Howard, he encouraged greater student involvement in the university. As a lawyer, he specialized in civil rights cases, especially school desegregation cases.

Nader, NAY duhr, Ralph (1934— ), an American lawyer, became famous for fighting business and government practices he felt endangered public health and safety. Nader also is an outspoken critic of the influence of large corporations on the American political system. In 1996 and 2000, he ran as the Green Party candidate for president of the United States. The Green Party's platform stresses environmental responsibility, respect for diversity, and social justice. Nader won only a small percentage of votes in either election, but his candidacy brought increased attention to the Green Party's causes.

In his book Unsafe at Any Speed (1965), Nader argued that the U.S. automobile industry emphasized profits and style over safety. The National Traffic and Motor Vehicle Safety Act of 1966, which established safety standards for new cars, resulted largely from his work.

Nader's studies of the meat and poultry industries, coal mines, and natural gas pipelines also resulted in stricter health and safety laws. He publicized what he felt were the dangers of pesticides, food additives, radiation from color TV sets, and excessive use of X-rays.

In 1988, Nader's efforts helped bring about the passage of California's Proposition 103, a law that provided for lowering some auto insurance costs. Nader won another battle in 1989 when General Motors announced it would make air bags standard equipment on many 1990 models. Nader had promoted the use of the safety feature for more than 10 years. In the 1990's, Nader also spoke out on such issues as campaign finance reform, trade policy, globalization, corporate abuse, universal health care, and criminal justice reform.

Nader was born in Winsted, Connecticut, the son of Lebanese immigrants. He graduated from Princeton University and Harvard Law School. Frederick E. Webster, Jr.

NAFTA. See North American Free Trade Agreement.

Nagana. See Tsetse fly.

Nagasaki, NAH guh SAH kee (pop. 444,599), is the Japanese city with which Westerners have had the longest contact. Its harbor was opened to foreign trade in 1571. After 1637, it was the only Japanese port where Westerners were allowed to trade. Dutch traders were permitted to set up a trading post on an island in the harbor, and one Dutch ship each year was allowed to call at the post. In 1857, it was one of the six Japanese ports opened to foreign trade.

Nagasaki is on the west coast of the island of Kyushu. It is important as the Japanese port city closest to the mainland of China. Nearby coal fields provide a source of soft coal for export. Nagasaki is on a landed dock bay, which is deep and large enough to hold many ships. For location, see Japan (political map).

Because Nagasaki has a large steel rolling mill, it is an important shipbuilding center. Many of its factories were destroyed on Aug. 9, 1945, by the second atomic
**Nagoya, nuh GOH uh** (pop. 2,171,378), is one of the largest cities in Japan. It is the capital of Aichi prefecture on the island of Honshu. It stands on Nobi Plain, facing Ise Bay (see Japan [political map]).

Nagoya was once the seat of the powerful daimyo (baron) of Owari, a province of early Japan. In 1610, a great castle was built in Nagoya by the powerful feudal lord Tokugawa Ieyasu. The castle was destroyed during World War II (1939-1945), but was rebuilt in 1959.

Nagoya is famous as a manufacturing center. It has an important textile industry. It also manufactures machines, pottery, porcelain, lacquerware, clocks, fans, and embroidery. Nagoya's industries and its population are crowded into a closely packed area.

See also Bible (Books of the Hebrew Bible).

**Nahum, NAH um. Book of,** is a book of the Hebrew Bible, or Old Testament, named for an Israelite prophet. Nahum lived in the kingdom of Judah during the second half of the 600's B.C. The book has three chapters. Chapter 1, a hymn, is a vision of God that may be the work of another author. In chapters 2 and 3, Nahum praises the capture and destruction in 612 B.C. of Nineveh, the capital of the hated and feared Assyrian empire. His description of the city is so vivid that some people believe he actually lived to witness Nineveh's fall. The poetic style of the book is among the most elegant in the Bible. Nahum's striking images of God's wrath along with images of God's refuge and safety lend great power and immediacy to the prophet's words.

Eric M. Meyers

See also Bible (Books of the Hebrew Bible).

**Naiad.** See Nymph (in mythology).

**Nail** is the most widely used fastener for attaching one piece of wood to another. Nails also join wood and such materials as cloth, sheet metal, and wire. Special nails hold wood and other materials to brick and concrete.

Most nails are made of steel, but some are made of aluminum, brass, copper, or stainless steel. Steel nails may be plated with aluminum, copper, nickel, or zinc to resist rust. Some nails have a coating of resin, an adhesive substance that makes them hold more tightly.

Carpenters generally use a claw hammer to drive nails. This kind of hammer has a claw for removing nails. Many carpenters who build or remodel houses use a power tool called an automatic nailer. This tool can drive nails more quickly than a regular hammer.

**The parts of a nail.** A nail has three main parts: (1) the point; (2) the Shank, or body; and (3) the head. The point acts as a wedge that separates the fibers of wood as the nail is driven. After the nail is in place, the fibers grip the shank and keep the nail from loosening. The head covers the hole made by the nail.

The most common type of nail point is the diamond point, a sharp point that works well in most kinds of wood. A blunt point works better in some hardwoods, such as maple and oak. This point breaks off some of the wood fibers and helps keep the wood from splitting.

Most nails have a smooth, round shank. Nails with a twisted, threaded, or ringed shank hold better but cost more. A narrow shank helps prevent splitting of hard-woods or of thin boards. Nails with a square shank are used to attach wood flooring to concrete.

Most kinds of nails have a broad, flat head. A nail with a narrow head can be hidden in the wood by driving it completely below the surface with a punchlike tool called a nailset. The hole left by the nail can be filled with putty and then painted. Roofers use a nail with an extra wide head to install shingles. Upholsterers use tacks with decorative heads if the tacks can be seen.

**Sizes of nails.** Nails are usually measured in units called pennies, designated by the letter d. Nails measured in this way range in size from 2-penny nails that are 1 inch (2.5 centimeters) long to 60-penny nails 6 inches (15 centimeters) long. Nails that are shorter or longer than those are measured in inches or centimeters. The system of measuring nails in pennies probably began in England several hundred years ago.

**How nails are made.** The earliest nails were made about 5,000 years ago in Mesopotamia. Artists used them to fasten sheets of copper to wooden frames to make statues. In the early 1700's, American colonists hammered nails by hand from a bar of hot iron. About 1775, Jeremiah Wilkinson, an inventor in Cumberland, Rhode Island, developed a process for cutting nails from a sheet of cold iron. About 1851, William Hassell (or Harsell), a machinist in New York City, invented the first machine for making nails from wire.

Today, almost all nails are made from wire by a machine that can produce more than 500 per minute. Wire is fed into the machine from a large coil. A set of cutters trims off a length of wire and forms the point of the nail at one end. At the same time, a hammer shapes the head.

**Some nail sizes**

---

**The length of a nail** may be specified in inches or centimeters, or by penny size. This illustration shows the actual size of various nails, using the various measurements.

The letter d stands for penny.

### Nail Applications

Nails are used in a variety of applications, including construction, furniture making, and upholstery. They are also used in various trades, such as plumbing, electrical work, and metal fabrication.
1965 to 1976. He was known for his accurate passing and skillful play selections. He passed for 27,663 yards and 173 touchdowns during his pro career. In 1967, Namath became the first pro quarterback ever to pass for more than 4,000 yards in a single season.

Joe William Namath was born in Beaver Falls, Pennsylvania. He starred at quarterback at the University of Alabama, which he attended from 1961 to 1963. Namath was drafted by the Jets when the team was a member of the five-year-old American Football League (AFL). His success helped lead to the merging of the AFL and the established National Football League (NFL) in 1970. In 1969, Namath helped lead the Jets to a 16-7 upset over the Baltimore Colts in Super Bowl III. Namath played his last NFL season in 1977 with the Los Angeles Rams. He was voted into the Pro Football Hall of Fame in 1985. He became a TV sports commentator and actor.

Carlon Stowers

**Name.** Everyone has a name, unless some extraordinary circumstance has isolated a person from all human contact. Some people have many names. In Western nations, most people have three names—two given names and a family name. The given name consists of a first name and a middle name. It is often called a Christian name. The family name is also called the surname or last name. All three names together make up the legal name. A person may also have one or more nicknames.

All names have meanings, though people today may not be aware of them. Documents reveal that early peoples gave someone a name with a definite knowledge of the meaning of the name. In the Bible, for example, a widow exclaims, "Call me not Naomi [unpleasant], call me Mara [bitter]; for the Almighty hath dealt very bitterly with me" (Ruth 1: 20). People in India, Israel, and some African nations still give names with specific meanings.

This article discusses the cultural and national characteristics of names and describes their origins. For information about proper etiquette in the use of names, see **Address, Forms of.**

**Given names**

Most of the common given names come from Hebrew, Greek, or Latin, or from Teutonic languages.

**Hebrew names** taken from the Bible have traditionally provided the most important source of Christian names. The most commonly used Hebrew names are **John** (gracious gift of God), **Mary** (wished for), and **Michael** (who is like God). Other common Hebrew names include **David** (beloved), **Elizabeth** (oath of God), **James** (may God protect, or one who takes the place of another), **Joseph** (the Lord shall add), **Hannah** (God has favored me), and **Samuel** (God has heard). These Biblical names occur in various forms among all Christian nations.

**Greek and Latin names** often refer to abstract qualities. Common Greek names include **Alex** (helper of humanity), **Barbara** (stranger), **George** (farmer), **Helen** (light), **Margaret** (pearl), **Philip** (lover of horses), and **Stephen** (crown or garland). Common Latin names include **Clarence** (famous), **Emily** (flattering), **Patricia** (of noble birth), **Víctor** (conqueror), and **Virginia** (maidensly).

**Teutonic names** are widely used and are among the most popular Christian names, especially boys' names. They usually consist of two elements joined together without regard to their relationship. For example, **William** is composed of two name elements, **Wil** (will, or resolution) and **helm** (helmet). But the name **William** does not mean "helmet of will" or "resolute helmet." It means "will, helmet." Some of these name elements are found at the beginning, as ead(rich) in **Edwin** and **Edward**. They may also occur at the end, as w(eard) (guardian) in **Howard** and **Edward**.

**Middle names,** or second Christian names, occur frequently today. Many people have as their middle name the **maiden name** of the mother—that is, the surname the mother had before her marriage. In France and Spain, double Christian names appeared in the Middle Ages. The Germans in Pennsylvania used several forenames in colonial times. But middle names did not become common in the United States until after the Revolutionary War (1775-1783).

**Other given names.** In the United Kingdom and the United States, family names may often be used as Christian names. Such names as **Percy,** Sydney, and **Lincoln** are now recognized Christian names. Some of the outstanding leaders in the United States, including Washington Irving, Hamilton Fish, Franklin Delano Roosevelt, and Jefferson Davis, had such names.

Traditionally, Roman Catholic parents have given a saint's name to a child. This is not difficult, because most common Christian names now have been borne by one or more saints.

**Ethnic names**

**Black names.** Before the 1960's, the names of black Americans resembled those of the white population. But after the rise of the civil rights movement in the 1960's, some blacks changed their names for religious reasons or to reflect their African heritage.

A number of blacks have converted to the Muslim religion and taken Muslim names. For example, the basketball star Ferdinand Lewis Alcindor, Jr., became Kareem Abdul-Jabbar. The boxer Cassius Marcellus Clay changed his name to Muhammad Ali.

Some blacks have given their children names from such African languages as Arabic, Igbo, Kikuyu, Swahili, or Yoruba. Children have such African names as **Aba** (born on Thursday), **Aduke** (much loved), **Marjanilcoral,** or **Dakarai** (happiness). The writer LeRoi Jones changed his name to Imamu Amiri Baraka. **Imamu means spiritual leader in Swahili. Amiri Baraka is an Arabic name.**

**Hispanic names.** In Spain and other Spanish-speaking countries, a child traditionally takes the surname of both the mother and the father. The father's name comes first. These names were formerly joined by **y,** the Spanish word for **and.** For example, **Julio,** the son of Rodrigo Ruíz y González and Maria López y Chávez, would have been known as **Julio Ruíz y López.** This custom, however, is no longer followed.

Among Spanish-speaking people in the United States, a hyphen may join the two names, as in **Julio Ruiz-López.** The name may also be shortened to **Julio Ruíz** to conform to the standard method of naming in the United States.

**American Indian names** reflect the culture of a particular tribe. Names are always symbolic, though each tribe has its own naming tradition. Sometimes names are kept secret because of religious laws.
Name

Generally, Indians have a birth name, such as Sunrise Beauty; a family name, Smooth Water; and an adult name, White Mountain. Another name may be occupational. For example, a construction worker may be called High Walker. For legal identification purposes, many Indians assume Americanized names, such as Willard Countryman or Frank Beaver.

In many tribes, a child has one name at birth and other names in later stages of life. As individuals take a new name, they discard the earlier one.

History of family names

Beginnings. The Chinese were the first known people to acquire more than one name. The Emperor Fuxi is said to have decreed the use of family names, or sur-
names, about 2852 B.C. The Chinese customarily have three names. The family name, placed first, comes from one of the 438 words in the Chinese sacred poem Baijia Xing (also spelled Po-Chia Hsing). It is followed by a gen-
eration name, taken from a poem of 20 to 30 characters adopted by each family; and a milk name, correspond-
ing to a Christian name. In the United States, the Chi-
ese often follow Western practice and put the family name last.

In early times, the Romans had only one name, but later they also used three names. The praenomen stood first as the person's given name. Next came the nomen, which indicated the gens, or clan. The last name, the cognomen, designated the family. For example, Caesar's full name was Calus Julius Caesar. A person sometimes added a fourth name, the agnomen, to commemorate an illustrious action or remarkable event. Family names be-
came confused by the fall of the Roman Empire, and sin-
gle names once again became customary.

The Middle Ages. Family names came into use again in northern Italy about the late A.D. 900’s, and became common about the 1200’s. Nobles first adopted family names to set them apart from the common people. The nobles made these family names hereditary, and they descended from father to children. The nobility called attention to their ancestors in this way. A family name became the mark of a well-bred person, so the common people began to adopt the practice too.

The Crusaders carried the custom of family names from Italy to the other countries of Western Europe. Throughout Europe, wealthy and noble families first adopted family names. At first, these were not heredi-
tary, but merely described one person. For example, the son of Robert Johnson might be known as Henry Rob-
erson, or Henry, son of Robert.

Origin of family names

It is difficult to work out a simple classification of family names, because of corruption and changes in spell-
ing and pronunciation. Many old words are new obso-
lete or have obsolete meanings. For many years, the spelling of names depended on the discretion of the writer. The same name might be spelled in different ways in the same document. Some names appear to come from English words, but they are from another language. Foreign names are often altered into more fa-
miliar words. The Dutch Roggenfelder (dweller in or near a rye field) became the American Rockefeller.

Family names have come down to us in a variety of ways. They may have developed from a person's sur-
roundings or job, or from the name of an ancestor.

Place names came from a person's place of resi-
dence. For example, if a man lived on or near a hill or mountain, he might be Mr. Maki, if from Finland; Mr. Dumont or Mr. Depew in France; Mr. Zola in Italy; Mr. Jurek in Poland; or Mr. Hill in England. In England, people might be known as Wood, Lake, Brook, Stone, or Ford because of their location. During the Middle Ages, few people could read. Signboards often exhibited the picture of an animal or object to designate a shop or inn. A person working or living at the place might be called Bell, Star, or Swan. A person might also be named after the town he or she came from, such as Middleton or Kronenberg. Many English place names may be recognized by the endings -ham, -thorp, -ton, -wic, and -worth, meaning a homestead or dwelling.

Occupation. Family names also come from a per-
son's job. Names like Baker, Carpenter, Clarke (the Brit-
ish pronunciation of clerks), Cook, Miller, and Taylor are quite common. The most common surname in English is Smith. It is also common in many other countries. It takes the form of Schmidt in Germany, Lefevre in France, Ferraro in Italy, and Kuznetzov in Russia.

Ancestor's name. Many people took surnames from their father's given name. Practically every language has a suffix or prefix meaning "son of." Some names that include the term "son of" include Irish names beginning with Mac or Mag, German names ending in -sohn or -son, and Scandinavian names ending in -son or -son.

Russian and Serbian names ending in -itch and Roma-

nian names ending in -escu have the same meaning. Those describing the bearer of the name as the son of John include Johnson and Jackson in England; Johns and Jones in Wales; Jensen, Jansen, and Hansen in Denmark; Jonsson and Johnson in Sweden; Jansowicz in Poland; Ivanov in Russia and Bulgaria; Janoski in Hungary; and MacEoin in Ireland. Irish names beginning with O' signi-
ified a grandson. Less common names indicating rela-
tionships include Brothers, Eames (uncle), and Wat-
mouth (Wat's brother-in-law).

Many surnames came from terms that described an ancestor. In the Middle Ages, most Europeans lived in small villages, and needed only a single name. When the village clerk had to note in his records that a villager named Robert had paid a tax, he often had to identify just which Robert was meant. The clerk would then add some descriptive word without consulting the man in-
volved. For example, he might call a man Robert, the small. Gross and Groth come from the German, and in-
dicate a fat or large person. Names like Reid, Reed, and Read are early spellings of "red" and refer to a man with red hair. These red-haired men probably received the nickname of "Red."

Other family names may have more than one origin. For example, the common English surname Bell may designate one who lived or worked at the sign of the bell, or it may refer to the bell maker or bell ringer. It may also indicate the descendant of Bel, or pet form of Isabel, or it may be a nickname for the handsome one, from the Old French word bel, or beautiful.

Jewish family names were the last to develop in most countries. In Europe, Jews usually lived apart from oth-
ers. Many did not feel the need for family names. Laws
The origin and meaning of some common given names

This table shows the origin and probable meaning of a number of given names. Many names are so old that scholars can only guess at their meaning.

Name	7

Sometimes a nickname results from a child's attempt to pronounce a word or name, as Lilibet for Elizabeth. In other instances, a nickname is a translation of the person's real name. Many persons called New York City's mayor, Fiorello H. La Guardia, The Little Flower, a literal translation of his Italian first name. In many other cases, a nickname may consist of a person's initials, such as F.D.R. for Franklin Delano Roosevelt. Pet, or nursery, names often consist of abbreviations of Christian names, such as Bob, Jimmie, and Debbie. They may be terms of endearment, or represent surnames, such as Smitty for Smith. Pseudonyms are fictitious names assumed for anonymity or for effect. A nom de plume (pen name) is a writer's pseudonym. Many authors have assumed pen names. For example, Voltaire was the pen name of François Marie Arouet. Eric Blair, an English writer, wrote under the name of George Orwell. See Pen name.

passed in the early 1800's compelled them to adopt surnames. Many Jews then chose pleasant combinations of various words like gold, silver, rose (rosen), mountain (berg), stone (stein), and valley (thal), to form such names as Goldberg, Silverstein, and Rosenthal. Others adopted names of cities where they were born, such as London and Modena. Some took names with religious connotations. Katz is an abbreviation of kohen zedek, Hebrew for priest of righteousness. Others took surnames from given names, such as Benjamin and Levy.

Other names

Nicknames may be either descriptive terms or pet names. Descriptive terms, such as Happy and Gabby, usually express a person's prominent characteristics. Physical characteristics account for the largest group of nicknames. Sometimes they go by contraries, as when a husky football player is called Tiny.
Namibia

An alias usually refers to the name taken by a criminal to disguise his or her identity. Incognito means the use of a fictitious name by a person, usually a celebrity, to avoid being recognized.

Stage names are names that some entertainers assume professionally. French actress Sarah Bernhardt's original name was Rosine Bernard. Many motion-picture performers have changed their names. For example, Frances Gumm was better known as Judy Garland.

The legal name of a person in the United States is the name by which he or she is known. Most legal names consist of a given name and a family name. Some states require that if a person does business under a name other than his or her own, the person must register it. A title, such as Mr., or a suffix, such as Jr., is not part of one's legal name. In many countries, names can be changed only by governmental permission. In the United States, a person can change a name without any court order. However, it is usually advisable to obtain a court order before changing the name.

Additional resources

Namibia, nuh MIHB ee uh, is a country in southwestern Africa. It was formerly named South West Africa. Windhoek is the capital and largest city of Namibia.

Most of Namibia's people are blacks, but the territory was controlled by the white government of neighboring South Africa from 1916 to 1990. In March 1990, after many years of negotiations, Namibia gained full independence from South Africa.

Much of Namibia's land is dry and unfertile. But the land is rich in mineral deposits, including diamonds and uranium.

Government. Namibia's government is headed by a president. The people elect the president to a five-year term.

Facts in brief
Capital: Windhoek.
Official language: English.
Official name: Republic of Namibia.
Area: 318,261 sq. mi. (824,292 km²). Greatest distances—east-west, about 880 mi. (1,420 km); north-south, about 820 mi. (1,320 km).
Coastline—925 mi. (1,489 km).
Elevation: Highest—Brandberg, 8,465 ft. (2,580 m) above sea level. Lowest—sea level, along the coast.
Population: Estimated 2002 population—1,768,000; density, 6 persons per sq. mi. (2 per km²); distribution, 73 percent rural, 27 percent urban. 1991 census—1,409,920.
Chief products: Agriculture—cattle, fish, sheep, corn, millet, vegetables. Mining—copper, diamonds, lead, uranium oxide, zinc.
Flag: A large blue triangle is in the upper left corner, and a large green triangle is in the lower right corner. A sun appears on the blue triangle. The triangles are separated by a red diagonal stripe bordered by white. Adopted 1990. See Flag (picture: Flags of Africa).
Money: Basic units—Namibian dollar and South African rand.

Namibia is a country in southwestern Africa. Windhoek, the capital city, has modern downtown buildings.
ence, the government began working to raise the economic level of the blacks.

Namibia's official language is English. But most black Namibians speak local African languages. About 15 such languages are spoken in the country. About 90 percent of the people are Christians. Lutherans form the largest Christian denomination. Other Christian groups, in order of size, are Roman Catholics, Anglicans, and members of Dutch Reformed Churches.

Public schools provide Namibians with free education. The University of Namibia (formerly the Academy for Tertiary Education) offers post-secondary education.

Land and climate. Namibia is bordered on the north by two large rivers, the Kunene and the Okavango. The Kwando River cuts through the Caprivi Strip. The Zambezi River flows along the northeastern border, and the Orange River forms Namibia's southern border. Otherwise, Namibia is a dry land. Droughts often occur.

The western border of Namibia stretches 950 miles (1,500 kilometers) along the Atlantic Ocean. Huge sand dunes of the Namib Desert lie near the coast. The Kalahari Desert occupies eastern Namibia. The inland territory is mostly a rolling plain about 4,000 feet (1,200 meters) above sea level. This area has stubby trees and enough grassland for grazing cattle and growing corn.

Large antelope live on the interior plain of Namibia. Elephants adapted to desert conditions inhabit the northwest corner of the country. Etosha Game Park, which is a huge reserve in north-central Namibia, has a variety of animals, including antelopes, cheetahs, elephants, giraffes, lions, rhinoceroses, and zebras.

Daytime temperatures in Namibia average 75 °F (24 °C) in January and 68 °F (20 °C) in June. Namibia receives most of its rain between December and March. The average annual rainfall totals about 20 inches (50 centimeters) in the north and about 8 to 16 inches (20 to 40 centimeters) in the center. The south receives only about 1 to 6 inches (2.5 to 15 centimeters) of rain a year.

Economy. Mining ranks as Namibia's most important economic activity. The chief minerals are diamonds, uranium, copper, lead, tin, and zinc. Traditionally, farming, livestock raising, and fishing have also been important economic activities. But drought and other problems have reduced farming and livestock activities, and overfishing has reduced fishing in the Atlantic. Most farmers grow only enough food crops for their own use. The chief farm crops include corn, millet, and vegetables. Cattle and sheep are the most important livestock. The fishing industry yields anchovies, mackerel, and sardines. Little manufacturing takes place in Namibia.

Namibia's leading exports include jewelry diamonds, uranium oxide, copper, lead, and zinc. Imports include wheat and other foods, as well as manufactured products. The chief trading partners include South Africa, Japan, the United States, and the United Kingdom.

Walvis Bay is the chief port. Namibia has about 1,450 miles (2,330 kilometers) of railroads that connect its major urban areas with one another and with South Africa. Namibia also has about 24,000 miles (38,600 kilometers) of roads, fewer than one-fourth of which are paved. An international airport is near Windhoek.

History. Both the Damara and the San people claim to be the original inhabitants of Namibia. Through the years, large numbers of Herero and Ovambo people moved to Namibia from the north. By the 1800's, the Damara, Herero, and Ovambo were the largest groups, and the Kavango and the Caprivians had settled where they now live. Other groups arrived in the 1800's.
Rural villages like the one shown here dot Namibia's landscape. Namibia's mostly dry land yields barely enough food for the people, but it provides valuable minerals.

Beginning in 1868, German settlers, missionaries, and soldiers colonized Namibia's coast. Germany annexed the land in 1884, calling it German Southwest Africa. In the 1890s, the Germans brutally forced the Herero and Damara out of the Windhoek area. The Herero began to revolt in 1904. By the time the Germans put down the revolt in 1907, they had killed about 65,000 Herero.

In 1915, during World War I, South African troops attacked the Germans and took over Namibia. The South Africans wanted to make Namibia part of their country. But the United States and other allied nations objected to that plan. In 1920, the newly formed League of Nations gave South Africa a mandate to manage Namibia's government and affairs. Yet, the South Africans governed Namibia as if it were a province of their nation.

The UN replaced the League of Nations in 1945. But South Africa refused to accept the authority of the UN and rejected its request to place Namibia under UN trusteeship. The UN took steps to try to bring Namibia under UN control. In 1966, the UN voted to end South Africa's mandate. In 1971, the International Court of Justice declared South Africa's control of Namibia illegal.

Black Namibians formed a political organization called the South West Africa People's Organization (SWAPO) in 1960. At first, SWAPO tried to persuade South Africa to grant Namibia independence. But beginning in the mid-1960s, it used guerrilla tactics to further its goal. In turn, South Africa set up armed forces along Namibia's borders with Angola and Zambia. Fighting occurred between SWAPO and South Africa until 1989.

In 1977, South Africa was preparing to grant Namibia independence under a plan that would give local political leadership to an assembly dominated by white Namibians. The UN strongly opposed such white domination. Representatives of the United States, the United Kingdom, West Germany, France, and Canada persuaded South Africa to negotiate a new plan that would meet the UN objection. Negotiations for independence were held at various times in the late 1970s and the 1980s.

Finally, in late 1988, South Africa agreed to a plan under which Namibia would gain full independence by April 1990. In April 1989, SWAPO and South Africa agreed to a cease-fire. Elections for a Constituent Assembly in Namibia were held in November 1989. In February 1990, the Assembly approved a constitution and elected Sam Nujoma, the leader of SWAPO, as Namibia's first president. Future presidents were to be elected by the people. Namibia gained independence on March 21, 1990. The Constituent Assembly was then renamed the National Assembly.

When Namibia became independent, South Africa kept the district of Walvis Bay, which included the major port of Walvis Bay. Namibian leaders said Walvis Bay should be part of Namibia. In March 1994, South Africa turned over control of Walvis Bay to Namibia. In 1994 and 1999, Namibia's voters reelected Nujoma as president.

Nan-ching. See Nanjing.

Nancy, NANT see or nahn SEE (pop. 105,830; met. area pop. 331,363), is a city in northeastern France. It lies on the Meurthe River, 6 miles (10 kilometers) north of the Meurthe's junction with the Moselle River. For location, see France (political map). Nancy is the commercial center of the Lorraine region. Factories in the city produce furniture, glassware, and electrical equipment. The city has a university, founded in 1572, and a school of forestry and mining.

Nanjing, nahn jihng (pop. 2,610,594), also spelled Nan-ching or Nanking, is an important center of industry, transportation, and government in east-central China. The city lies on the Yangtze River, about 200 miles (320 kilometers) from the East China Sea. For location, see China (political map). Nanjing is the capital of Jiangsu Province and was once the capital of all China.

The city. Government office buildings, two museums, and a stadium are in the center of Nanjing. Commercial and residential areas lie outside the central area. Most of Nanjing's people live in apartment buildings or in apartments above shops. The remains of an ancient defensive wall surround the built-up areas of Nanjing.

Most of Nanjing's people travel by bicycle or public bus. Trucks transport most products in the city, but some goods travel in carts pulled by animals.

Wharves that can handle oceangoing ships line the banks of the Yangtze River, which borders Nanjing on the west. East of the city are Xwanwu Lake, a tourist attraction with several islands; and Zijin Mountain, the site of an astronomical observatory. The tomb of Sun Yatsen, who helped establish the Republic of China in 1912, lies on the mountain. Nanjing's educational institutions include Nanjing University, engineering colleges, and a medical school.

Economy. Nanjing has hundreds of manufacturing plants. Leading products include cement, fertilizers, iron and steel, porcelain, textiles, and trucks. Nearby mines provide iron ore for the iron and steel plants. Several communes (farm communities) operate outside the city. The farmers raise cotton, rice, wheat, vegetables, and other crops.

Railroads connect Nanjing to Beijing, the capital of China, in the north and to Shanghai in the east. Numerous ships dock at the wharves of the city. A double-deck bridge that extends 3 miles (5 kilometers) across the
Yangtze River serves both trains and motor vehicles.

**History.** People have lived in what is now the Nanjing area since about the 400’s B.C. Early settlers chose the site because of its location near a river and some roads. From A.D. 420 to 1421, the city served as the capital of various local Chinese dynasties (series of rulers of the same family). The Ming dynasty gained control of most of China in 1368. The first Ming ruler made Nanjing—which means southern capital—the seat of the dynasty. In the early 1400’s, the Mings moved the capital to Beijing—which means northern capital.

In 1853, rebels called the Taipings seized Nanjing from the Manchus, who ruled China at that time. The Taipings made the city the capital of their empire. The Manchus regained Nanjing in 1864.

In 1912, Chinese revolutionaries overthrew the Manchus. The new rulers met in Nanjing and founded the Republic of China. From 1928 to 1937, the city served as the capital of the republic. Japanese forces captured Nanjing in 1937 and burned much of the city. Nanjing again became China’s capital in 1946, the year after Japan’s surrender ended World War II.

The Chinese Communists took over China in 1949. They made Beijing the capital, but Nanjing remained a center of regional government. During the 1950’s, 1960’s, and 1970’s, the Communists built hundreds of manufacturing plants in Nanjing. The city quickly grew into a major industrial center. Parris H. Chang

**Nanking.** See Nanjing.

**Nanking Massacre** is a name for the brutality committed by Japanese troops against the people of Nanking (Nanjing), China, in 1937, during the Sino-Japanese War. The Sino-Japanese War led into, and became part of, World War II (1939-1945). Also called the Rape of Nanking, the massacre began on December 13—the day after the Japanese entered Nanking, at that time the capital of Nationalist China—and lasted for six weeks. During that period, Japanese forces engaged in widespread cruelty, rape, looting, arson, and murder of unarmed Chinese. Sometimes acting on orders, and often masquerading in small groups, Japanese troops burst into businesses, private homes, and even areas under foreign protection to search for Chinese men of military age and for young women. Many of the men, and prisoners of war captured earlier, were gathered together and then murdered. Many women were raped by Japanese soldiers.

Experts disagree about the number of Chinese injured or killed by the Japanese during the Nanking Massacre. The full extent of this atrocity can never be determined precisely. At the time, the Japanese had no interest in counting the dead, and the Chinese had no way of accurately totaling up their losses. Neutral observers of many nationalities, shocked by what they witnessed, recorded the horrifying details in reports, letters, photographs, and even motion pictures. The death toll probably exceeded 100,000 at Nanking, though some estimates now place the figure as high as 300,000. Rapes of women may have numbered 20,000 or more. Many of these victims were then killed or died from their assaults.

The Nanking Massacre occupied a central place in Chinese efforts to win international support for their cause in the war against Japan. The Chinese stressed the cruel behavior of the Japanese invaders. The wartime Japanese government, in contrast, told its people only that the capture of Nanking, the enemy's capital and symbol of Nationalist China, was a grand achievement. After the war, many Japanese were charged with war crimes and punished for the massacre after Chinese military trials were held. The International Military Tribunal for the Far East sentenced the Japanese commander at Nanking, General Matsui Iwane, to death. He was hanged on Dec. 23, 1948. Theodore F. Cook, Jr.

**Nanotechnology**, Nanh tehkh NAEHL uh jee, is the precise manipulation of individual atoms and molecules to create larger structures. Nanotechnology involves engineering on the nanometer scale. Nano means billionth. A nanometer is 0.000000001 meter (1/1,000,000,000 meter) or approximately 1/10,000 the width of a human hair or 3 to 5 times the diameter of a single atom. Nanotechnology is also called molecular engineering or molecular manufacturing.

**The promise of nanotechnology.** Many scientists and engineers believe that nanotechnology may someday create devices so small they could only be seen with powerful microscopes. Such devices might include supersensitive sensors that could detect single atoms of a contaminant or other substance. But the applications of nanotechnology are not restricted to creating tiny objects. Nanotechnology could also be used to make large objects, such as automobiles or computers, starting with building blocks the size of an atom or molecule.

**The challenge of nanotechnology.** One of the challenges of nanotechnology is to find a way to assemble things on a molecular scale. Scientists have manipulated individual atoms with a powerful microscope called a scanning probe microscope. This device uses a tiny probe to map out an object's surface at the atomic level. But the probe can also be used to pick up and arrange individual atoms or molecules. Manipulating atoms one by one is extremely time-consuming, however.

Another process, called self-assembly, may be a more effective method of creating nanoscale objects, also called nanostructures. Self-assembly is common in nature. It is the process, for example, by which an acorn grows into an oak tree rather than another plant. Scientists believe it may be possible for organic or biological
molecules to direct the self-assembly of nanostructures.

**Types of nanostructures.** Scientists have produced two kinds of nanostructures: (1) nanocrystals and (2) nanotubes. Nanocrystals are nanometer-sized clusters of atoms. They have unusual optical, electronic, and magnetic properties. For example, certain types of nanocrystals emit light when they absorb energy. But the color of light emitted depends on the size of the crystal.

Another type of nanocrystal has an unusual property related to its ability to conduct (carry) electric current. A sufficiently small sample of this nanocrystal can change from a metal—an excellent conductor—to an insulator. This change can occur at a constant temperature and pressure and without any change in the nanocrystal's chemical makeup.

Nanotubes are tubular structures of carbon atoms several nanometers in diameter and several thousand nanometers in length. Each nanotube is actually a single carbon molecule (see Carbon f;Forms of carbon). Nanotubes are about 100 times stronger than steel. Some serve as conductors, while others are insulators or semiconductors. A semiconductor is a material that conducts electric current better than an insulator but not as well as a conductor.

Nanometer-scale objects have physical and chemical properties distinct from those of larger objects of the same material. The properties of nanometer-scale objects change systematically and smoothly with size according to what are called scaling laws. Using these laws, engineers should be able to design advanced materials that act in various ways merely by changing the size of the components.

Armand Paul Alivisatos

**Nansen, NAY suhn or NAHN suhn, FRIDTJOF, FRIHT yahf** (1861-1930), was a famous Norwegian polar explorer. He was also a humanitarian, a statesman, a marine zoologist, and a pioneer oceanographer.

Nansen made his first Arctic cruise in 1882 as a zoological collector aboard a whaler. In the summer of 1888, he and five other men made the first east-to-west crossing of the huge ice sheet that covers Greenland, a feat experts had declared impossible.

Nansen hoped to obtain valuable scientific information by exploring the North Polar Basin. For this expedition, he had a ship built to withstand the grinding ice floes. This ship was named the *Fram* (Forward). Nansen left Norway in the *Fram* on June 24, 1893. He deliberately let the ship become jammed in ice north of Siberia. For the next three years, the ice drift carried the ship across the Arctic Ocean to waters near Svalbard. In the second year, Nansen and Hjalmar Johansen left the *Fram* and tried to reach the North Pole with kayaks and sleds. They came within 272 miles (438 kilometers) of the pole, nearer than anyone before them. After meeting many dangers, they boarded a British ship at Franz Josef Land in 1896 and went to Norway. See Arctic Ocean (maps).

Nansen played a prominent part in the separation of Norway from Sweden in 1905. From 1906 to 1908, he served as Norwegian minister to the United Kingdom. When he returned to Norway, he became a professor of marine zoology (later oceanography) at the University of Christiania. He went on ocean voyages in 1910, 1912, 1913, and 1914, and published his results in many books. His writings include *Farthest North* (1897) and *In Northern Mists* (1911).

After World War I, Nansen was Norway's delegate to the League of Nations. He aided Soviet refugees in Asia Minor and directed the return of German and Soviet war prisoners to their homelands. He devised the *Nansen passport*—an identification certificate for refugees. He received the 1922 Nobel Peace Prize for his services. Oceanographers use a metal container, called a Nansen bottle in honor of him, to trap seawater. Nansen was born on Oct. 10, 1861, in Christiania (now Oslo).

William Barr

**Nantes, nants or nahnt** (pop. 277,728; met. area pop. 544,932), is a port city in western France, near the mouth of the Loire River (see France [political map]). A ship canal connects the city with the port of St.-Nazaire on the Bay of Biscay, an arm of the Atlantic Ocean. Shipping and shipbuilding are the major industries of Nantes.

Other economic activities include food processing and the production of copper, steel, and aviation and railroad equipment. The city is the capital of the Loire region and the Loire-Atlantique department (administrative district). Landmarks include a castle, built in its present form in the 1400's, and the Cathedral of St. Peter and St. Paul, which also dates from the 1400's.

Gauls built a town on the site of what is now Nantes many years before Roman soldiers established a settlement nearby in the 50's B.C. In A.D. 1598, King Henry IV of France signed the famous Edict of Nantes in the city's castle. The edict granted limited religious liberty to Protestants (see Nantes, Edict of). Mark Kesselman

**Nantes, nants or nahnt; Edict of,** was the first official recognition of religious toleration by a great European country. King Henry IV of France signed the edict in the city of Nantes on April 13, 1598. Before the edict was signed, there had been 50 years of internal warfare and religious division in France.

The edict allowed French Protestants, called Huguenots, control of about 100 fortified towns for 8 years. They were also given freedom of conscience, social and political equality with the Roman Catholic majority, and a certain degree of freedom of worship. The edict was seriously enforced only until the king's death in 1610. It was revoked by King Louis XIV in 1685. As a result, about 200,000 Huguenots left France.

Dale A. Johnson

See also Huguenots; Henry IV (of France).

**Nantucket, nan TUHK uht** (pop. 9,520), is a summer resort on Nantucket Island, off the southern coast of Cape Cod, Massachusetts (see Massachusetts [political map]). The name was taken from the Indian word *Nanticoct*, meaning *The Faraway Land*. There are many summer homes in Nantucket because of the scenery and mild climate. Nantucket's beaches, bike paths, shops, and restaurants also attract tourists.

During the late 1700's, Nantucket became one of the greatest whaling centers in the world. As many as 125 whaling ships had their home port there. Charles I of England granted Nantucket Island to his brother the Duke of York in 1641. The island belonged to the province of New York from 1660 to 1692, when it became a part of Massachusetts.

Laurence A. Lewis

**Napalm, NAY pahlm,** is a powder used to thicken gasoline for use in war. When napalm is added to gasoline, the result is a jel!-s gasoline often called *napalm*.

A napalm bomb dropped from the air bursts, ignites, and splatters burning napalm over a wide area. The jel-
lied gasoline clings to everything it touches, and burns violently. Napalm causes death from burns or suffocation. Napalm is also used in flame throwers carried by ground troops (see Flame thrower). Napalm was used in World War II (1939-1945), the Korean War (1950-1953), the Vietnam War (1957-1975), and the Persian Gulf War (1991).

Frances M. Lussier

Naphtha, NAP thuh or NAF thuh, is any liquid composed only of hydrogen and carbon that boils below 450 °F (233 °C). Naphthas obtained during the refining of petroleum are blended to make gasoline. Some types of naphtha are used to dissolve rubber and to thin paints and varnish. Others are used as a cleaning agent and as an ingredient in the manufacture of artificial gas.

Naphtha can also be made when coal tar, a sticky substance made from soft coal, is distilled. Coal tar naphtha is used as a dissolving agent. It is also used in synthetic (artificial) resins. Pure naphtha is highly explosive when exposed to an open flame. 

Geoffrey E. Dolbear

Napier, NAY pee uhr or nuh PEER, John (1550-1617), Laird of Merchiston, was a Scottish mathematician. He developed methods of rapid calculation, which he sought to apply to astronomy, trigonometry, navigation, mapmaking, and surveying. Napier discovered how to multiply numbers by doing the easier task of adding other, corresponding numbers that he called logarithms (see Logarithm). Logarithms are used to describe mathematically many natural phenomena. Napier also invented a set of "rods" or "bones" that could be arranged for arithmetical calculations. He was born near Edinburgh, Scotland.

Judith V. Grabiner

Naples, NAY pulz (pop. 1,067,365), is the third largest city of Italy. Only Rome and Milan are larger. Naples lies at the foot of a range of low hills on the west coast of southern Italy. For location, see Italy (political map).

Naples ranks as a major manufacturing center, and the Bay of Naples makes it an important seaport. Tourists come from all parts of the world to see the many places of scenic and historical interest in the Naples area. The city's name in Italian is Napoli.

About 600 B.C., Greek colonists from Cumae, 14 miles (23 kilometers) to the west, founded a town near the site of present-day Naples. They called the town Parthenope and later renamed it Neapolis (New City). The people of Naples are still called Neapolitans. During much of the period from the 1100's until 1860, Naples was the capital of a kingdom. This kingdom included most of southern Italy and the island of Sicily. Since 1861, the city has been the capital of Campania, a political region of Italy.

The city. In the eastern section of Naples, church spires rise above old tenement buildings and factories. The Spaccia-Napoli district, with its crowded, narrow streets, forms the heart of old Naples. The newer western part of the city lies along the Riviera di Chiaia, a broad drive that runs along the Bay of Naples. A hilly, densely populated modern section called the Vomero lies inland.

The Cathedral of St. Januarius, completed in 1323, honors Naples' patron saint. Castles in the city now house museum collections or government offices. The oldest of these structures, the Castel dell'Ovo (Castle of the Egg), takes its name from its shape. The Castel Sant'Elmo, built in the 1300's and enlarged in the 1500's, served as a prison for many years. The city's attractions also include a botanical garden and a public park. The park has one of Europe's finest aquariums.

Naples lies amid some of the most spectacular scenery in Europe. Artists from many countries go there to paint the landscape or the people. Mount Vesuvius, the only active volcano on the mainland of Europe, rises 7 miles (11 kilometers) southeast of the city. It erupted in A.D. 79, burying the ancient Roman cities of Pompeii and Herculaneum, which are within 20 miles (32 kilometers) of Naples. The ruins of these cities are important archaeological sites for the study of life in Roman times. Capri and Ischia, islands famous for their pleasant climate and scenic beauty, lie to the south across the Bay of Naples. Vineyards and citrus groves dot the hillsides on the bay's eastern shore. Just west of Naples, the Posillipo district offers a lovely view of the Bay of Naples.

Way of life. Music plays an important part in Neapolitan life. Such songs as "O Sole Mio," "Funiculì, Funiculà," and "Santa Lucia" have made the city's music familiar in many parts of the world. At the Piedigrotta, an annual music festival, the people hold an outdoor competition to choose the best of the new popular songs. The Teatro San Carlo, one of the largest opera houses in Italy, has presented the first performance of many famous operas.

Naples lies at the foot of low hills along the beautiful Bay of Naples. Volcanic Mount Vesuvius, rear, adds to the city's scenic beauty. Naples is a leading Italian port and manufacturing center.
Neapolitan food includes many varieties of dishes made with spaghetti, macaroni, or other pasta. Naples is the birthplace of pizza, which a baker invented in 1889 to honor the queen of Italy. Neapolitans also eat much fish and other seafood.

The National Archaeological Museum in Naples displays one of the world's largest collections of ancient art objects. The collection includes glassware, mosaics, paintings, pottery, and statues from Herculaneum and Pompeii; and ancient Greek sculpture. The royal palace of Capodimonte, built in the 1700's as a residence for the kings of Naples, houses the National Gallery. The gallery owns a collection of paintings, porcelain, sculpture, and tapestries. The National Library is the largest of the city's several libraries. It holds thousands of rare manuscripts. The Carchiusan monastery of St. Martin, which adjoins the Castel Sant'Elmo, features a museum collection devoted to the art and history of Naples. The University of Naples, the best known of the city's many schools and colleges, was founded in 1224 by Emperor Frederick II.

**Economy.** Products manufactured in Naples include automobiles, cement, chemical products, locomotives, office machinery, ships, and textiles. The highly industrialized area in and around the city has the greatest concentration of factories in southern Italy. Ships from every part of the world use Naples' harbor. Naples still produces many traditional wares for which it became known through the years. They include kidskin gloves, wine, and articles made of coral and tortoise shell, such as combs and jewelry. Despite its industries, Naples suffers from a high rate of unemployment.

**History.** After more than a century as a Greek colony, Naples came under Roman control about 326 B.C. The city's beauty and mild climate made it a favorite resort of wealthy Romans. The poet Virgil lived in Naples for more than 20 years and is buried on a nearby hill.

After the fall of the Roman Empire in A.D. 476, various peoples fought for control of Naples and the rest of southern Italy. The Byzantines, Franks, Lombards, Normans, and Germans controlled the city for periods during the Middle Ages. Naples came under Spanish rule in 1442, and Spain held it for most of the next 250 years.

Austria ruled Naples in the early 1700's. During this period, Naples was Italy's largest city and one of the largest cities of Europe. In 1734, the city became the capital of an independent kingdom, which was also called Naples. A Spanish branch of the royal Bourbon family governed this kingdom and Sicily. During the Napoleonic Wars (1799-1814), Naples had a series of French rulers, including Napoleon's brother, Joseph Bonaparte. The Bourbons regained power in 1815. In 1816, they formally combined Naples and Sicily to form the Kingdom of the Two Sicilies, which they ruled until 1860. In 1861, the Kingdom of the Two Sicilies became part of the newly formed kingdom of Italy.

During World War II (1939-1945), bombs destroyed many buildings in central Naples and the port area. The damaged areas were rebuilt, but a housing shortage remained. In the 1970's, the Italian government began working to relieve the shortage. In 1980, however, a severe earthquake destroyed many buildings in Naples. During the 1980's, the government provided new housing outside the city. In the 1990's, the city administration helped to modernize Naples by enlarging the airport, improving public transportation, and extending hours at museums and galleries.

**Naples, Bay of,** is an inlet of the Tyrrhenian Sea on the southwest coast of Italy near the city of Naples. The bay lies between Cape Miseno and the Isle of Ischia on the north and the Sorrento Peninsula and the Isle of Capri on the south. Mount Vesuvius, an active volcano, rises adjacent to the bay near Naples. The bay is famous for the beauty of its coastline and its deep blue waters. The waters near Naples are polluted. The southern shores of the bay have many tourist resorts. See also Naples (picture).  

Howell C. Lloyd

**Napoleon I** (1769-1821), also known as Napoleon Bonaparte, crowned himself emperor of the French. He was the greatest military genius of his time and perhaps the greatest general in history. He created an empire that covered most of western and central Europe.

Napoleon was also an excellent administrator. He introduced many useful reforms, including the creation of a strong, efficient central government and the revision and organization of French laws into collections called codes. Many of his reforms are evident today in the in-

National Gallery of Art, Washington, D.C.; Samuel H. Kress Collection (photo by Lyle Petersen)

stitions of France and of areas once under its control.

Napoleon stood 5 feet 2 inches (157 centimeters) tall, about average for Frenchmen of his time, though most French generals and statesmen were taller. He earned the nickname le Petit Caporal (the little corporal) in 1796 at the Battle of Lodi, near Milan, Italy. In the battle, General Bonaparte startled his troops by personally aiming the cannon, a risky job usually performed by a corporal. Napoleon was an inspirational and dramatic leader. He could also be cynical and demanding, though this side of his character was usually hidden from the public. In addition, Napoleon had great energy and ambition. He personally directed complex military maneuvers and at the same time controlled France's press, police system, foreign policy, and domestic affairs. He chose capable subordinates and rewarded them generously with medals, wealth, military rank, and titles of nobility.

Napoleon's ambition ultimately led him to overextend his power. His downfall also resulted in part from feelings of nationalism in areas invaded by French troops and from economic hardship brought on by Napoleon's attempts to exclude British goods from continental Europe. Other factors that contributed to his downfall included bitter reaction to the taxes and conscription (the draft) that he imposed across his empire and opposition to Napoleon of many of Europe's royal rulers.

Boyhood. Napoleon was born on Aug. 15, 1769, in Ajaccio, on the island of Corsica in the Mediterranean Sea. The year before his birth, France had bought Corsica from the Italian city-state of Genoa. Napoleon was the fourth child and second son of Carlo and Letizia Ramolino Buonaparte later given the French spelling Bonaparte. Napoleon's parents were members of noble Italian families. Carlo Buonaparte was an eloquent lawyer and a prominent citizen of Corsica. Napoleon's mother was beautiful and strong-willed.

In 1779, at the age of 9, Napoleon entered a French military school at Brienne-le-Château, a town in France near Troyes. Napoleon was an average student in most subjects, but he excelled in mathematics. In 1784, he was selected for the elite military academy Ecole Militaire in Paris, from which he graduated a year later.

Early military career. In January 1785, at the age of 16, Napoleon received a commission in the French Army, as a second lieutenant of artillery. He joined an artillery regiment and briefly attended the royal artillery school in Auxonne, near Dole. He was promoted to first lieutenant in 1791 and to captain in 1792.

The French Revolution broke out in 1789 (see French Revolution). During the early 1790s, Napoleon spent many months in Corsica on leave from the French Army. While there, he served in the Corsican National Guard. But in France, he joined a radical political society known as the Jacobins. Many Jacobins wanted to make France a democratic republic. Napoleon's membership in the society brought him into conflict with the governor of Corsica, Pasquale Paoli, who was a royalist (supporter of the French monarchy). After the revolutionary French government executed King Louis XVI in January 1793, Paoli declared the Bonaparte outlaws, and the family fled to France. Napoleon then returned to the French Army.

In June 1793, a group of Jacobins led by Maximilien Robespierre gained control of the French government (see Robespierre). Several French cities revolted against Robespierre's regime. At Toulon, the rebels were aided by a British naval fleet. When the French artillery commander at Toulon was wounded, Napoleon was sent to take his place. In December 1793, Napoleon positioned the artillery on high ground overlooking the harbor at Toulon and fired down on the British ships. The fleet withdrew and French troops gained control of Toulon. For his role in the victory, Napoleon was named brigadier general at the age of 24.

Napoleon's star had risen, but soon seemed about to set. In July 1794, Robespierre fell from power and was executed. In August, Napoleon was imprisoned for about a week. After his release, he returned to the army.

The "whiff of grapeshot." In 1795, Napoleon was in Paris when angry mobs there tried to attack the ruling National Convention at the royal palace called the Tuileries. The mobs had been encouraged by royalists who hoped to destroy the convention before it could install a new moderate government. The convention was protected by troops under Vicomte Paul de Barras. Barras had seen Napoleon in action at Toulon and now sent for him. Napoleon defended the palace with point-blank cannon fire. This cannon fire, which became known as the "whiff of grapeshot," killed or wounded hundreds of people and quickly cleared the streets. Napoleon was hailed as a hero and promoted to major general. The new government, called the Directory, was installed with Barras as one of its five directors.

Marriage. In 1796, Napoleon married Josephine de Beauharnais, a beautiful woman of French descent from Martinique in the West Indies. Josephine's first husband, Vicomte Alexandre de Beauharnais, had been sent to the guillotine during the Reign of Terror (see French Revolution [Terror and equality]). When Napoleon met her, Josephine was a leader of fashionable French society. She was six years older than Napoleon, and had two children by her previous marriage.

Rise to power

Victories in Italy. From 1792 to 1795, France had been at war with much of Europe. By 1796, Austria had become France's chief enemy. Days after marrying Josephine, Napoleon left Paris to take command of a French army on the Italian-French border—an underfed, ill-equipped force of about 38,000 men. The Directory

hoped that he could tie up Austrian forces in Italy while larger French armies won the war by marching through Germany and attacking Vienna, Austria’s capital.

Instead, Napoleon won the war. In less than a year, he defeated four armies, each larger than his own. He won a final victory by marching over the Alps and threatening Vienna in early 1797. In October, France and Austria signed the Treaty of Campoformio, which enlarged France’s territory. Napoleon returned to Paris, where once again he was hailed as a hero.

Military strategy. Napoleon had by now developed a highly successful military strategy that was to form the basis of his future campaigns. He would start a battle while holding back as large a reserve as possible. He would then seek the weakest point in the enemy’s lines and throw all his strength against that point at the decisive moment. Napoleon had an extraordinary ability to recognize the best time to attack.

Egypt invaded. When Napoleon returned to Paris after defeating Austria, he already had political ambitions. However, he felt that he did not yet have enough influence to gain control of the government. Instead, he concentrated on strengthening his military reputation. Late in 1799, the Directory offered to put Napoleon at the head of an invasion of England. But he declined the offer. Instead, he proposed that he invade Egypt to destroy British trade with the Middle East. The Directory agreed to the plan. In May 1798, Napoleon sailed for Egypt with about 38,000 men.

Napoleon reached Egypt in July. There, he defeated the Mamelukes, Egypt’s military rulers, in the Battle of the Pyramids near Cairo (see Mamelukes). On August 1, however, the French fleet anchored in Abu Qir Bay was destroyed in the Battle of the Nile by a British fleet commanded by Lord Horatio Nelson. As a result, Napoleon’s army was stranded in Egypt. Turkey then formed an alliance with Great Britain and Russia and declared war on France. In 1799, Napoleon’s troops invaded Turkish Syria and advanced as far as the fortress Acre (now Akko, Israel), which Napoleon failed to capture. Meanwhile, Napoleon learned that a Turkish army was preparing to invade Egypt. He retreated to Egypt, where he met and defeated the Turks at Abu Qir, near Abu Qir Bay. About this time, Napoleon learned that Austria, Britain, and Russia had formed a coalition against France and had defeated the French army in Italy. He left his army in the command of General Jean Kléber and sailed for France.

First consul of France

News of Napoleon’s victory at Abu Qir arrived with him in Paris. The French people, who had lost confidence in the Directory, cheered the return of the young hero. Napoleon formed key political alliances and seized control of the French government on Nov. 9, 1799, in a bold move known as the Coup d’État of Eighteenth Brumaire. A new constitution overwhelmingly approved by the French people replaced the Directory with a three-member Consulate. Napoleon became first consul. The other two consuls served merely as advisers to Napoleon. After 10 years of revolution and civil disorder, the French wanted a strong leader. Napoleon could now rule France as a dictator.

Peacemaking. As first consul, Napoleon sought peace. In May 1800, he led a famous march across the Alps, through the Great St. Bernard Pass and into the Po Valley of northern Italy. In June, his army surprised and defeated the Austrians in the Battle of Marengo. In 1801, the Austrians signed the Treaty of Lunéville, which re-affirmed the Treaty of Campoformio. With Austria defeated, the war-weary British agreed to peace in 1802 in the Treaty of Amiens. Russia had dropped out of the coalition against France in 1799. For the first time in 10 years, Europe was at peace.

Administrator and lawmaker. Napoleon proved to be a superb civil administrator. One of his greatest achievements was his supervision of the revision and collection of French law into codes. The new law codes—seven in number—incorporated some of the freedoms gained by the people of France during the French Revolution, including religious toleration and the abolition of serfdom. The most famous of the codes, the Code Napoléon or Code Civil, still forms the basis of French civil law (see Code Napoléon). Napoleon also centralized France’s government by appointing prefects to administer regions called departments, into which France was divided.

The Napoleonic empire

French aggression. Napoleon was not content simply to govern France. His thoughts soon turned to conquest. At first, he sought to extend French influence in the Western Hemisphere. In 1800, Napoleon forced Spain to cede to France the Louisiana Territory in North America. But the army that he sent to take possession of the territory was destroyed in the French colony of Haiti by a slave revolt and by tropical disease. Frustrated, Napoleon abandoned his plans for the Western Hemisphere and turned his attention to Europe. By 1803, France had annexed the Piedmont region of northwestern Italy and Napoleon had become president of the Italian Republic, which bordered Piedmont on the east. Also, fearful of Britain’s naval power, Napoleon had tried to stop British trade with the rest of Europe. He anticipated war with Britain and in 1803 sold the Louisiana Territory to the United States to raise money for the war. War with Britain began later that year.

Crowned emperor. In 1802, the French people had overwhelmingly approved a constitutional amendment that made Napoleon first consul for life. In May 1804, the French Senate and people voted him their emperor. Napoleon crowned himself emperor on December 2 in ceremonies at the Cathedral of Notre Dame in Paris.

Dominates Europe. By 1805, Austria, Russia, and Sweden had joined Britain in a new coalition against France. In September 1805, Napoleon led his troops into Germany. In October, he captured an Austrian army at Ulm. In December, he demolished the Austrian and Russian armies at Austerlitz. But earlier that year Lord Nelson had destroyed the fleets of France and Spain, France’s ally, near Trafalgar, a cape on Spain’s southern coast. This victory gave Britain control of the seas and ended any chance of Napoleon’s invading Britain.

In 1806, Prussia joined Russia in mounting a new campaign against France. In October, Napoleon’s forces overwhelmed the Prussian army at Jena and at nearby Auerstedt. In June 1807, Napoleon demolished Russian armies at Friedland. In 1809, he defeated the Austrians again at Wagram, near Vienna.
Napoleon became the ruler of France in 1799. By 1812, his empire covered most of Europe. Napoleon was defeated at Leipzig in 1813 and was forced to give up the French throne in 1814. He later formed another army but was defeated at Waterloo in 1815. The map shows his major battles.

After each victory, Napoleon enlarged his empire. In 1806, he set up the Confederation of the Rhine, made up of a number of western German states, and placed it under his protection. He also carved provinces of Germany and Italy into principalities and dukedoms, and gave them to friends and relatives. In 1806, he made his brother Joseph king of Naples, and his brother Louis king of Holland. In 1807, Napoleon made his brother Jerome king of Westphalia and added to France the Grand Duchy of Warsaw. In 1809, he gave his sister Elisa the Grand Duchy of Tuscany and annexed to France the Illyrian Provinces, which covered much of what are now Slovenia and Croatia. In 1810, he brought his empire to its height by annexing Holland and much of Germany.

**Divorce and remarriage.** By 1809, Napoleon had grown concerned about what would become of his vast empire after his death. Josephine, who was now 46 years old, had no children by him, and Napoleon had no heirs. In December, he divorced Josephine to marry a younger woman. In April 1810, he married the 18-year-old Archduchess Marie Louise, daughter of Emperor Francis I of Austria. In 1811, the couple had a son, also named Napoleon, who was given the title king of Rome.

**Fall from power**

In 1806, Napoleon had issued the Berlin Decree, which barred British ships from ports under French control. The decree was aimed at destroying British trade with continental Europe. In 1807, Napoleon issued the Milan Decree, which was intended to prevent the ships of neutral nations from carrying British goods to continental Europe. Such ships were attacked by French vessels. The system established by the Berlin and Milan decrees for blocking British trade was known as the Continental System.

Portugal, which had long been friendly with Great Britain, refused to follow the Berlin Decree. In 1807, the French gained control of Portugal and occupied parts of
Spain. In 1808, French forces under Marshal Joachim Murat seized control of Madrid, Spain's capital. Napoleon removed King Ferdinand VII from the Spanish throne and appointed his brother Joseph king of Spain. Murat took Joseph's place as king of Naples.

The Peninsular War began in 1808 when Spanish and Portuguese forces rebelled against French rule. Soon after the war began, British troops joined the fight against France on the peninsula that consisted of Portugal and Spain. By April 1814, all French forces had been driven from the peninsula. Tens of thousands of French soldiers died in the war, and the loss of Spain and Portugal greatly damaged Napoleon's prestige.

Disaster in Russia. On Dec. 31, 1810, Czar Alexander I of Russia withdrew from the Continental System. Napoleon felt that the czar's withdrawal threatened France, and so he assembled a new army to attack Russia. Many years of war had weakened France, but Napoleon raised about 600,000 men. His allies and subject nations furnished by conscription many of these soldiers. The Russian army had about 200,000 men.

In June 1812, Napoleon's army crossed the Neman River into Russia. The Russians retreated, denying Napoleon a decisive battle. In September, Napoleon fought the Russians at Borodino, near Moscow. The battle resulted in many casualties on both sides but produced no clear winner. Again, the Russians withdrew.

Napoleon pushed on to Moscow only to find the city nearly empty of people. Soon after the French army entered Moscow, large parts of the city were destroyed by fires that had been set by the retreating Russians. With the bitter Russian winter approaching, Napoleon waited in Moscow for Alexander to offer peace, but no such offer came. In mid-October, Napoleon, unable to supply his troops, began the long retreat from Moscow. His soldiers struggled against snowstorms and freezing temperatures. Soldiers and horses died of starvation and exposure. Russian soldiers called Cossacks killed many of the stragglers. Of the 600,000 men in Napoleon's army, about 500,000 died, deserted, or were captured during the campaign and the retreat from Russia.

After he returned to Paris, Napoleon admitted the disaster in his famous 29th Bulletin. The French continued to support him, but news of the devastating campaign encouraged his enemies throughout Europe.

The enemy alliance. After his return from Moscow, Napoleon faced a hostile alliance of Austria, Britain, Russia, Prussia, and Sweden. In April 1813, Napoleon arrived in Germany with a new army and took the offensive against the allies. He won initial victories at Lützen, Bautzen, and Dresden, but his forces were vastly outnumbered. In October, the two sides fought at Leipzig in the Battle of the Nations. In the battle, Napoleon was defeated, and he retreated into France. The allies pursued him and captured Paris in March 1814.

Exile to Elba. At Fontainebleau on April 11, 1814, Napoleon abdicated (gave up) the imperial throne. The allies called for the return of a king of the Bourbon family and placed Louis XVIII, the brother of Louis XVI, on the French throne (see Louis XVIII). Napoleon was exiled from France and made ruler of the tiny island of Elba off the northwest coast of Italy. His wife and son were sent to his wife's father, the emperor of Austria. Napoleon never saw his wife or son again.

On Elba, Napoleon planned his return to France. In February 1815, he sailed from the island with about 1,100 followers who had shared his exile. He landed at Cannes on March 1 and began marching to Paris, gathering supporters along the way. Troops led by Marshal Michel Ney were dispatched from Paris to arrest Napoleon. But when they saw their old leader, the men gladly joined him and hailed him as their emperor. Louis XVIII fled Paris as Napoleon approached. On March 20, Napoleon entered Paris and was carried on the shoulders of cheering crowds into the Tuileries.

The Hundred Days and Waterloo. Napoleon immediately proclaimed a new constitution that limited his powers. He promised the allies that he would not make war. But the allied leaders considered Napoleon an "enemy and disturber of the peace of the world." Once again, both sides prepared for battle.

Napoleon advanced into Belgium with about 125,000 men, hoping to defeat the separate armies of Britain's Duke of Wellington and the Prussian Marshal Gebhard von Blücher. On June 16, Napoleon defeated Blücher at Ligny, near Fleurus. On June 18, Napoleon attacked Wellington at Waterloo in what has become one of history's most famous battles. The battle featured spectacular charges by thousands of French cavalry. But just as it seemed the British forces would collapse, Blücher's troops arrived to reinforce Wellington. Badly outnumbered, the French army suffered a crushing defeat.

Napoleon fled to Paris and abdicated for the second time, on June 22. The period from Napoleon's return to Paris from Elba to his second abdication is known as the Hundred Days. Napoleon tried to escape to the United States, but he failed and surrendered at Rochefort to Frederick Lewis Maitland, the captain of the British battleship Bellerophon. In August, Napoleon was sent to the barren British island of St. Helena, in the South Atlantic Ocean (see Atlantic Ocean (map)).

On St. Helena, Napoleon spent much of his remaining years dictating to friends his version of the events that occurred during his lifetime. He died on May 5, 1821, of a stomach ulcer that was probably cancerous. Most historians label as inaccurate a theory that he died of arsenic poisoning. Napoleon was buried on the island. In his will, Napoleon had asked to be buried "on the banks of the Seine, among the French people I have loved so much." In 1840, the British and French governments had his remains brought to Paris. There, at the Église du Dôme (Church of the Dome), which is part of the Hôtel des Invalides (Home for Disabled Soldiers), the body of Napoleon was laid to rest.

Napoleon's place in history

Napoleon is both a historical figure and a legend—and it is sometimes difficult to separate the two. The events of his life have fired the imaginations of great writers, filmmakers, and playwrights whose works have done much to create the Napoleonic legend.

Napoleon was one of the greatest military commanders in history. But he has also been portrayed as a power-hungry conqueror. He denied being such a conqueror. He argued that he had tried to build a federation of free peoples in a Europe united under a liberal government. He did intend, though, to achieve this goal by concentrating power in his own hands. However, in the
states he created, Napoleon granted constitutions, introduced law codes, abolished feudalism, created efficient governments, and fostered education, science, literature, and the arts. Owen Connelly

Napoleon II (1811-1832), Duke of Reichstadt, RYKHE STAHT, was the son of Emperor Napoleon I of France and his second wife, Marie Louise of Austria. Napoleon I had long hoped for a son to inherit his empire, and he gave his newborn son the title of king of Rome.

When Napoleon I was overthrown in 1814, he gave up the throne in favor of his young son. But the French Senate did not recognize Napoleon II as emperor, and Louis XVIII, a member of the Bourbon royal family, became king of France that year. Marie Louise then took her son to live at the court of her father, Emperor Francis I of Austria. After Napoleon I was defeated at the Battle of Waterloo in 1815, he again proclaimed his son emperor of France. However, the French refused to give the young boy the throne, and he remained in Austria. His mother's family gave him the title of Duke of Reichstadt in 1818.

Napoleon II was never strong, and he grew into a tall, slender youth. He died of tuberculosis at the age of 21 and was buried in the Habsburg (or Hapsburg) family's church tomb in Vienna. In 1940, Adolf Hitler, dictator of Germany, had the body placed near that of Napoleon I in the Eglise du Dome (Church of the Dome) at the Hotel des Invalides (Home for Disabled Soldiers) in Paris. Napoleon II was born on March 12, 1811, in Paris.

Peter N. Stearns

Napoleon III (1808-1873) ruled as emperor of France from 1852 to 1870. His public works programs transformed Paris, but failures in foreign policy became his undoing.

Early life. He was born on April 20, 1808, in Paris, the son of Louis Bonaparte, king of Holland and brother of French Emperor Napoleon I. His full name was Charles Louis Napoleon Bonaparte, but he was usually called Louis Napoleon. A French law of 1816 exiled the Bonapartes from France, and Louis Napoleon spent his youth in Italy, Germany, and Switzerland. He became the head of his family in 1832. He was connected with such revolutionary groups as the Carbonari in Italy. He tried to overthrow the French monarchy of Louis Philippe in 1836 and 1840. He was imprisoned in the French fortress of Ham following the 1840 expedition. He escaped to England in 1846. During these years, he wrote his Napoleonic Ideas (1839), idealizing the career of his famous uncle, and The Extinction of Poverty (1844), proposing that the government act to end poverty and suffering.

Becomes emperor. When the Revolution of 1848 led to the Second Republic in France, Louis Napoleon returned and was elected to the Assembly. In December, benefiting by the glamour of his name, he was elected president by a large margin. He swore an oath to the republic, but in December 1851, he managed to concentrate all power in his hands. He abolished the republic and proclaimed himself emperor in 1852.

Napoleon's domestic policies were conflicting. He ruled as a dictator and was surrounded by dishonest adventurers. Although all men could vote, the legislature was powerless and the press could not publish legislative debates. When, after 1860, Napoleon moved in the direction of a liberal empire, it was too late. Liberal opponents continued to urge the overthrow of his government. Yet Napoleon keenly realized the problems of the industrial age. He favored state help for industries, banks, railroads, and the poor. He also backed major construction projects in Paris to modernize the city and to limit uprisings by the French people.

Foreign affairs. Napoleon tried to settle disputes
through international conferences, and he sympathized with claims of nationalism. He helped with independence for Romania, unification for Italy, and, unwittingly, unification for Germany.

Napoleon announced when he became emperor, "The Empire means peace," yet he led France into a long series of unfortunate adventures in other countries. In 1849, he helped overthrow the Roman Republic and restore the pope. He joined the United Kingdom and the Ottoman Empire in 1854 in the Crimean War against Russia. He secretly promised in 1859 to help the Count di Cavour drive the Austrians from Italy, in return for the promise of Nice and Savoy. But Napoleon withdrew from the war when he saw that Italy, instead of forming a weak confederation, would be united. He supported a scheme making Maximilian, the Archduke of Austria, emperor of Mexico in 1864. Napoleon hoped to increase French prestige, but United States pressure in 1867 forced him to withdraw his troops and leave Maximilian to be shot. Napoleon also supported French expeditions in central Africa and in what is today Vietnam.

His defeat. Otto von Bismarck, the prime minister of Prussia, wanted to unite Prussia and all the other German states into one country. Napoleon feared that a unified Germany would weaken France's power in Europe, and he hoped to keep Germany divided. Tensions between France and Prussia grew until they exploded in the Franco-Prussian war of 1870. France, however, was not prepared for war. The Germans easily defeated the French, seized territory in eastern France, and created the German Empire. Napoleon surrendered to the Germans at Sedan, France, on Sept. 2, 1870, with 80,000 troops. Two days later, supporters of a new French republic overthrew Napoleon's empire. Peter N. Stearns

Narcissus, nahr SIHS uhs, is the name of a large group of early spring flowers with lovely blossoms. They grow from brown-coated bulbs. They were named for the legendary Greek youth Narcissus. Narcissuses are native to Europe and Asia, but many are cultivated in North America. People like them because they have fragrant and delicately fashioned blossoms of yellow, white, or sometimes pink or orange. The narcissus is a special flower of December. In Europe, in the springtime, fragrant masses of wild narcissuses cover the Alpine meadows. Narcissus bulbs are poisonous.

There are various types of narcissuses. All of them send up shoots with sword-shaped leaves. The flowers have six petals surrounding a trumpet- or cup-shaped tube, which may be long or short. Many botanists consider daffodils to be long-trumpet narcissuses. Jonquils are short-trumpet narcissuses. Gardeners usually plant narcissus bulbs in the fall. The flowers are perennial.

Another short-trumpet species is the poet's narcissus. It produces a single, wide-open blossom on each stalk. Generally, the blossom has white petals surrounding a short, yellowish cup with a wrinkled red edge.

The paperwhite narcissus is a short-trumpet species that can be grown indoors in winter from bulbs placed on pebbles. Most cultivated types have large clusters of pure white flowers that are very heavily scented. When breeders cross the paperwhite narcissus with the poet's narcissus, they get improved varieties, including types with flowers of two different colors on the same plant. People value these beautiful hybrids.

August A. De Hertogh

Scientific classification. Narcissus belong to the amaryllis family, Amaryllidaceae. The daffodil is Narcissus pseudo-narcissus. The poet's narcissus is N. poeticus; the paperwhite is N. tazetta.

See also Bulb; Daffodil; Jonquil.

Narcissus, nahr SIHS uhs, in Greek mythology, was a handsome youth who was courted by many lovers for his beauty. He, however, haughtily rejected all of them, including the nymph Echo. As punishment for his cruelty, the gods condemned Narcissus to contemplate his beauty reflected in a pond on Mount Helicon in Greece. Day after day he lay beside the pond, gazing lovingly at his reflection until he wasted away and died. When searchers looked for him, they found only a flower, now called the narcissus. Echo also wasted away from her love for Narcissus, finally becoming nothing more than a voice in the woods. The best-known version of the Narcissus story appears in the Metamorphoses, a collection of tales by the Roman poet Ovid.

Jon D. Mikalon

Narcolepsy, NAHR kuh LIP see, is a disease that causes excessive sleepiness. People with narcolepsy tend to fall asleep several times a day, even though they get enough sleep at night. The exact cause of the disease is unknown, but much evidence indicates that it is hereditary. Doctors can treat narcolepsy with medication, but it cannot be cured.

Narcolepsy has several symptoms in addition to excessive sleepiness. Narcoleptics experience episodes (attacks) in which their muscles suddenly collapse though they remain awake. This condition is called cataplexy. Many cataplectic episodes are brought on by strong emotions, especially anger and laughter, and last two minutes or less. A person with narcolepsy may also experience sleep paralysis and hypnagogic hallucinations. In sleep paralysis, the person suddenly becomes unable to move as he or she is falling asleep or waking up. A person with hypnagogic hallucinations experiences vivid, realistic sights and sounds that do not really
exist as he or she falls asleep.

Scientists believe the symptoms of narcolepsy are related to REM (Rapid Eye Movement) sleep, the phase of sleep during which people dream. The eyes move rapidly in this phase, and the body is paralyzed while dreams occur. Narcoleptics experience this same sort of paralysis—while awake—during cataplectic episodes. They may feel tremendously tired during the daytime due to an unusual need for REM sleep. Ernest Hartmann

See also Amphetamine (Medical uses); Cataplexy; Sleep.

Narcotic is a substance that has a strong depressant effect upon the human nervous system. Narcotic substances cause insensibility to pain, stupor, sleep, or coma, according to the amount taken. The term narcotic comes from a Greek word meaning to make numb.

Narcotics include opium, codeine, morphine, and heroin. When a narcotic is given in doses large enough to cause sleep or coma, the drug is called a hypnotic. The term analgesic is applied to a drug that relieves pain without causing unconsciousness. The same narcotic may be either an analgesic or a hypnotic, depending on the dosage.

Narcotics produce an analgesic effect by interacting with specific nerve cells called receptors in the central nervous system. Several chemicals that occur naturally in the body, including endorphins and enkephalins, interact with the same receptors. Scientists believe these naturally occurring chemicals control the brain's perception of pain. See Endorphin.

Narcotic drugs are extremely useful in medicine, but they also have dangerous effects. Large doses of narcotics may cause death. The careless use of opium and substances made from it to relieve pain has frequently caused a drug habit. No one should use these and other narcotics except under the direction of a physician.

The United States carefully regulates the importation of narcotics as well as the manufacture and distribution of narcotic by-products. Physicians must state certain facts on narcotic prescriptions, and drugstores must keep records of them. The Drug Enforcement Administration in the United States Department of Justice oversees all narcotics laws. Barbara M. Bayer

Naragonsett Indians, Nar uh Gahn siht, were a tribe that lived on the west side of Narragonsett Bay, in what is now Rhode Island. The Narragonsett spoke an Algonquian language. They made their living by hunting, fishing, and farming and by gathering edible plant foods. The tribe's name is also spelled Narraganset.

At first, the Narragansett were friendly to the English colonists who settled in the area. But relations gradually grew worse. In 1675, more than 4,000 Naragonsett joined forces with Wampanoag Indian chief King Philip to drive out white settlers. But colonial troops killed all but about 100 warriors. In 1676, English settlers took over the Narragansett lands. Conrad E. Heidenreich

Narváez, nahr VAH ayth, Pánfilo de, PAHM fee loh thay (1470?-1528), was a Spanish soldier, explorer, and Indian fighter. He helped conquer Cuba in 1511 and lost an eye trying to arrest Hernando Cortés in Mexico in 1521. Holy Roman Emperor Charles V granted him the unexplored land of Florida in 1526, and he led an expedition there in 1528. Landing near Tampa Bay, he marched inland and lost many of his men in storms and Indian attacks. Having been cut off from their ships, Narváez and his men built five crude barges. They sailed along the coast to what is now south Texas. Narváez's boat was forced out into the Gulf of Mexico by winds and currents, and he was drowned. He was born in Valladolid. Helen Delpar

Narwhal, NAHR hwuhl, is an unusual whale of the Arctic. The male has a spiral ivory tusk about 8 feet (2.4 meters) long jutting out of its upper jaw, slightly to the left of center. This tusk is the narwhal's only tooth. A few narwhals have two tusks, with the right one underdeveloped. The female usually has no tusk. The tusks of most adult narwhals are worn at the tip and are often heavily scarred. Males sometimes fight each other with them.

Narwhals grow up to 17 feet (5.2 meters) long, not including the tusk, and weigh up to 2 tons (1.8 metric tons). They are grayish on top, whitish underneath, and have dark brown spots. Older narwhals are mostly white, with dark pigment spots on the head and neck. Arctic peoples hunt narwhals. They eat the skin and use the bone and ivory to make tools. Bernd Würsig

Scientific classification. The narwhal belongs to the whale order, Cetacea. It is Monodon monoceros.

See also Whale (picture: Some kinds of whales).

NASA. See National Aeronautics and Space Administration.

Nasby, Petroleum Vesuvius (1833-1888), was the pen name of David Ross Locke, a popular American humorist. Locke strongly supported temperance (avoidance of alcoholic beverages), abolition of slavery, women's rights, and integrity in government. He presented Nasby as a scoundrel who displayed the prejudices and excesses Locke himself opposed. Locke wrote many satirical letters as Nasby and also impersonated the character in lectures. The Nasby letters feature the comic mispellings and ungrammatical sentences that were popular among humorists of the day.

Locke was born on Sept. 20, 1833, in Vestal, New York. His first Nasby letter was published in 1862. Nasby's writings were collected in The Nasby Papers (1864), Swingin' Round the Circle (1866), and Nasby in Exile (1882). His other works include poetry, plays, and novels.

David B. Kesterson

Nasdaq, NAZ dakh, is the oldest electronic stock market in the world. The market's official name is The Nasdaq Stock Market. Originally, its name was an acronym for the National Association of Securities Dealers Automated Quotations System (Nasdaq). On the Nasdaq market, brokers called market makers buy and sell stocks through a vast computer network instead of on a trading floor. Participants around the world receive trading information over this computer network. Nasdaq lists nearly 5,000 stocks, including those of many high-technology companies, such as computer manufacturers and software developers.

The National Association of Securities Dealers, the world's largest self-regulatory organization for the securities industry, created the Nasdaq network in 1971. This
network automated the selling of over-the-counter (OTC) stocks, which are stocks not listed on any stock market or exchange. Nasdaq became a stock market in 1975 when it began listing stocks. In 1990, Nasdaq stopped dealing in OTC stocks and changed its name to The Nasdaq Stock Market.

See also American Stock Exchange.

Nash, Charles William (1864-1948), was a pioneer in the United States automobile industry. He became president of the Buick Motor Company in 1910, reorganized the company, and made it financially successful. Nash was elected president of General Motors Company (now General Motors Corporation) in 1912 when it was close to bankruptcy. The company prospered under Nash’s leadership. Nash resigned from General Motors in 1916. He then bought the Thomas B. Jeffery Company, an automobile firm from which he formed Nash Motors Company. He was president of the company until 1932 and board chairman until he died. The Nash firm merged with Hudson Motors in 1954, and became American Motors. Nash was born on Jan. 28, 1864, in De Kalb County, Illinois. William L. Bailey

Nash, John Forbes, Jr. (1928- ), is an American mathematician. He contributed greatly to the development of game theory—a method of studying strategic decision-making situations in which the choices of different participants influence one another. Nash proposed a solution for game situations in which no participant will benefit by changing strategy, thereby creating a balanced and stable point of the system. This concept, known as Nash equilibrium, has influenced many fields, including economics, political science, computer science, and biology. Nash also developed important concepts used in conflict resolution and negotiations.

Nash was born in Bluefield, West Virginia, on June 13, 1928. He received a Ph.D. degree from Princeton University in 1950. He taught at the Massachusetts Institute of Technology (MIT) from 1951 to 1959, when his career was interrupted by periods of mental illness. He later returned to Princeton. Nash shared the 1994 Nobel Prize in economic sciences with the Hungarian-born American economist John C. Harsanyi and the German economist Reinhard Selten.

Roberto Serrano

See also Game theory.

Nash, Ogden (1902-1971), was a famous American writer of humorous and satirical poetry. He created a unique poetic style in his light-hearted verses.

Most of Nash’s poems have lines of unequal length. He often stretched sentences over several lines to produce surprising and comical rhymes. In "The Terrible People," for example, Nash wrote:

People who have what they want are very fond of telling people who haven't what they want that they really don’t want it, And I wish I could afford to gather all such people into a gloomy castle on the Danube and hire half a dozen capable Draculas to haunt it.

Nash also used many puns and frequently made clever comparisons of apparently unrelated subjects. He sometimes invented words or misspelled real words to produce a carefully planned effect.

Although Nash wrote in a comic style, many of his poems make a serious point. He made satirical comments about American society and ridiculed what he considered foolish behavior, including his own. Nash described people as bewildered by all the complications of modern life. He regarded humor as the best means of surviving in a difficult world.

The first collection of Nash's verses, Hard Lines, was published in 1931. His other collections include Many Long Years Ago (1943) and You Can't Get There From Here (1957). I Wouldn't Have Missed It (1975) appeared after his death. Frederic Ogden Nash was born on Aug. 19, 1902, in Rye, New York. Many of Nash’s poems were first published in The New Yorker magazine.

William Harmon

Nashe, Thomas (1567-1601), was an author who wrote some of the first works of prose fiction in English literature. He is remembered chiefly for The Unfortunate Traveller or, The Life of Jack Wilton (1594), a forerunner of the English novel. This energetic narrative combines colorful fictional characters with references to actual people and events. Pierce Penniless, His Supplication to the Devil (1592) is a satire on Elizabethan society.

Nashe was born in Lowestoft, England. His name is also spelled Nash. He studied at Cambridge University and was one of the group of playwrights known as the "University Wits." Nashe's racy style and gift for rough language lent themselves to the pamphlet warfare that was widespread in Elizabethan literary life. In one famous series of pamphlets, Nashe attacked scholar Gabriel Harvey. Nashe also wrote several pamphlets in 1589 and 1590 that defended the bishops of the Church of England against attacks by the Puritans. This heated exchange of pamphlets became known as the Martin Marprelate controversy.

John N. King

Nashua, NASH oo uh (pop. 86,603; met. area pop. 190,949), is the second largest city in New Hampshire. Only Manchester has more people. Nashua lies on the junction of the Merrimack and Nashua rivers (see New Hampshire [political map]). The city's products include computers, electronic equipment for the military, and fabricated metal products. The first permanent settlement was made there between 1665 and 1670. A town charter was granted in 1673 under the name of Dunstable. The town was renamed Nashua in 1837. The early settlers referred to the Indians who lived in the area as the Nashaways. Nashua was incorporated as a city in 1853. It is the home of Rivier and Daniel Webster colleges. A mayor and board of aldermen head the city's government.

Claudette Durrocher

Nashville (pop. 569,891; met. area pop. 1,231,311) is the capital and second largest city of Tennessee. Only Memphis has more people. Nashville lies in the north-central part of the state (see Tennessee [political map]). It is often called the Athens of the South because of its many educational institutions and its buildings in the Greek classical style. Nashville is also called Music City, U.S.A. because it is a major music recording center and the home of "The Grand Ole Opry" radio show.

Nashville was founded in 1779 by settlers from North Carolina looking for fertile farmland. The settlers built a log stockade on a bluff overlooking the west bank of the Cumberland River. They called the settlement Fort Nashborough after Brigadier General Francis Nash, who was a hero in the Revolutionary War in America (1775-1783).
Nashville is the capital of Tennessee and a music recording center. This photo shows the State Capitol, right, and the War Memorial Building, left.

The settlement was renamed Nashville in 1784.

**The city.** Nashville covers all of Davidson County, an area of 330 square miles (1,373 square kilometers). It is one of the nation's largest cities in area. The Nashville metropolitan area covers 4,135 square miles (10,710 square kilometers) and consists of eight counties.

The Cumberland River flows through downtown Nashville. The State Capitol overlooks Memorial Square. The 33-story BellSouth Building in downtown Nashville is the tallest structure in Tennessee.

Most of the people of Nashville were born in the United States. The city's largest ethnic groups include those of French, German, or Irish ancestry. African Americans form about a fourth of Nashville's population. About 5 percent of the city's people are Hispanics.

**Economy.** Large numbers of Nashville's people work for the state government. Many others have jobs with agencies of the federal or city government. Vanderbilt University combined with its medical center ranks as one of the city's largest employers.

Nashville is the headquarters for a number of major companies. The city also has more than 600 industrial plants. Its chief products include aircraft parts, food products, glass, heating and cooking equipment, printed materials, recordings of music, tires, and trucks. General Motors and Nissan automobile manufacturing plants are located near the city. Nashville's economy received a big boost during the 1950's, when the city became a major music recording center. More than 180 recording companies, 20 recording studios, and 400 song-publishing firms operate in the city.

Three interstate highways reach Nashville. Freight railroads and Nashville International Airport serve the city. Barge lines connect the city with ports on the Cumberland River. The Tennessean is the daily newspaper.

**Education.** The metropolitan Nashville public school system consists of about 125 schools and about 65,000 students. The city has about 40 private and parochial schools. Vanderbilt University is the largest of the city's institutions of higher education. Other colleges and universities in the city include Belmont University, Fisk University, Lipscomb University, Meharry Medical College, Scarritt College for Christian Workers, Tennessee State University, and Trevecca Nazarene University.

**Cultural life and recreation.** The city's arts groups include the Nashville Symphony Orchestra, the Nashville Ballet, and theater groups. The Tennessee State Museum is in Nashville. An exact replica of the Parthenon of Athens stands in Centennial Park. The Tennessee Centennial of 1897 was held in the park.

The Hermitage, the home of President Andrew Jackson, lies about 10 miles (16 kilometers) east of Nashville. Jackson and his wife are buried on the grounds of the mansion.

Nashville is the home of the Nashville Predators of the National Hockey League and the Tennessee Titans of the National Football League. The nearby Nashville Super-speedway hosts Indy and stock car races.

**Government.** Nashville has a mayor-council form of government. The voters elect the mayor and the 40 council members to four-year terms.

**History.** The first white people who came to what is now the Nashville area found Shawnee Indians living along the Cumberland River. More settlers arrived after the establishment of Fort Nashborough in 1779. By 1780, the settlement consisted of seven forts with a total population of 300. Tennessee became a state in 1796, and Nashville was chartered as a city in 1806.

The first steamboat arrived in Nashville about 1818, and a brisk trade developed between Nashville and ports along the Ohio and Mississippi rivers. Various cities, including Kingston, Knoxville, and Murfreesboro, served as the capital of Tennessee. Nashville became the permanent capital in 1843. By 1850, the city's population had reached 10,165.

During the American Civil War, Union troops held Nashville from 1862 until the fighting ended in 1865. Confederate General John B. Hood tried to recapture the city in 1864 but was defeated by Union General George H. Thomas. In 1900, Nashville had a population of 80,865. The busy river trade, plus income from the fertile farmlands surrounding the city, contributed to Nashville's prosperity. From 1920 to 1930, the city's population increased from 118,342 to 153,866.

In 1962, Nashville and Davidson County adopted a metropolitan form of government. This government combines city and county functions under one administration and provides services for the entire county.

An urban renewal project for downtown Nashville, completed in 1980, included the widening and landscaping of city streets and the construction of office buildings. Also in the late 1900's, the Nashville Convention Center and Riverfront Park were completed.

Patrick S. 'Pat' Embry

For the monthly weather in Nashville, see Tennessee (Climate). See also Tennessee (pictures).

Naskapi Indians, NAS kuh pee, are a Far North tribe that lives in Schefferville, Quebec, and in Davis Inlet, a
village near Hopedale, on the northeast coast of Labrador, Canada. Nearly 400 Naskapi live in Schefferville and hold a variety of jobs. Most of the approximately 200 members of the tribe who live in Davis Inlet catch fish and hunt seals off the coast. The Naskapi speak an Algonquian dialect related to Macro-Algonquian, which is one of the 10 Indian language groups.

Before the 1900's, the Naskapi lived most of the year in the rugged forests and plains of the Labrador interior. They had moved there in the late 1700's and the early 1800's to hunt caribou, which lived on the plains. These animals supplied the Naskapi with food and clothing. The caribou also provided hide for tents and bone for needles and knives. In the fall, several Naskapi bands united to hunt caribou. In winter, the Naskapi lived on meat that they had stored, and hunted caribou on the animals’ winter feeding grounds. In spring and summer, fish and small game provided food for the tribe.

The Naskapi of Davis Inlet moved to the coast in the early 1900's because of a severe decline in the number of caribou. However, the tribe still has an annual caribou hunt in fall and winter. James A. Tuck

See also Indian, American (illustration: Indian ways of life).

Nasmyth, NAY smith, James (1808-1890), a Scottish engineer, invented the steam hammer in 1839. His steam hammer was able to forge large parts for steamships and railroads. He also developed the self-acting principle in machine-tool design, by which a mechanically held tool moves along a track and works on a stationary workpiece. Using this principle, Nasmyth invented a planing mill and a nut-shaping machine.

Nasmyth was born on Aug. 19, 1808, in Edinburgh. In 1829, he became assistant to a tool designer and manufacturer. In 1834, he started the Bridgewater Foundry at Manchester, which gained fame for machine-tool and steam-engine construction. He retired in 1856 and devoted his time to studying astronomy. David F. Channell

Nassau, NAS aw/pop. 135,437, is the capital and largest city of the Bahamas. The city borders an excellent harbor on the northeast coast of New Providence Island. For the location of Nassau, see Bahamas (map). Its warm, sunny climate has made it a major tourist center.

Near Nassau's harbor are beautiful beaches and luxurious hotels. Nassau also features fine restaurants, colorful markets, and casinos. Most major banks, stores, and government buildings are on Bay Street, which runs along the harbor. Nassau has several historic buildings, including three forts built in the 1700's. The nation's only college, the College of the Bahamas, is in Nassau.

Many of Nassau's people work in the tourist industry and are prosperous. But the city has few manufacturing industries, and unemployment is high. Some Nassau residents live in charming, pastel-colored houses. In the city's older, poorer neighborhoods, people live in rundown houses, some of which have no running water.

Nassau's busy harbor serves as a port for cruise ships that carry tourists to the city. Smaller ships called mail-boats move freight and passengers between Nassau and the many islands that make up the Bahamas. Such products as fish, oil, and rum are shipped through Nassau.

English seafarers founded a settlement named Charles Towne at what is now Nassau in the 1660's. The settlement was renamed Nassau in 1695. During the late 1600's, many pirates used Nassau as a base to attack Spanish ships sailing from Cuba or Mexico. The Bahamas became a British colony in 1717, with Nassau as the capital. Nassau became prosperous during the American Civil War (1861-1865), when ships carried goods from the city to the Confederate States. It also prospered during the U.S. Prohibition Era (1920-1933) as a distribution center for the illegal shipment of alcoholic beverages into the United States. Tourism has been Nassau's principal industry since 1929. In that year, commercial airline flights began operating between the United States and Nassau. In 1973, the Bahamas gained independence from the United Kingdom. Stephen C. Dodge

Nasser, NAH seh r, Gamal Abdel, gah MAHL AHB duhhl (1918-1970), led the revolt that overthrew King Faruk in 1952 and established Egypt as a republic. Nasser served as prime minister from 1954 until he was elected president of Egypt in 1956. Later that year, a world crisis occurred after Egypt seized the Suez Canal, then under international control. Nasser wanted to use the tolls collected from users of the canal to build the Aswan High Dam. When Syria and Egypt formed the United Arab Republic (U.A.R.) in 1958, Nasser became its president. Syria withdrew from the U.A.R. in 1961.

Nasser's book, Egypt's Liberation: The Philosophy of the Revolution (1955), stated his aim to unite all Arabs under Egyptian leadership. Although his efforts toward this goal failed, he became one of the most influential leaders in the Arab world. Nasser favored a neutral foreign policy. His guiding principles were nationalism and economic reform. Nasser redistributed land to farmers and also advanced education. His efforts to develop Egypt's economy were hampered by overpopulation.

Born on Jan. 15, 1918, in Alexandria, Egypt, Nasser graduated from the Royal Military Academy in Cairo. He fought in the Arab war against Israel in 1948 and 1949. Justin McCarthy

Nasser, Lake. See Lake Nasser.

Nast, Thomas (1840-1902), was an American political cartoonist. He popularized the famous political symbol of the Democratic donkey and originated the Republican elephant and the Tammany Tiger (see pictures with Democratic Party; Republican Party). His caricatures of the Tammany Tiger helped break up the notorious political organization headed by William "Boss" Tweed in New York City (see Tweed, William Marcy).

Nast's cartoons began to run in the popular magazine Harper's Weekly in the 1860's. He did his best work during the American Civil War, when his political cartoons
Nast drew the Tammany Tiger to symbolize the corrupt Tammany political machine in New York City. This cartoon appeared after the machine defeated its Republican opponents in 1871.

influenced public opinion in favor of the North. In the presidential campaign of 1872, Nast's barbed cartoons helped bring about the defeat of Horace Greeley (see Greeley, Horace). Nast is also credited with creating the present-day image of Santa Claus in sketches that appeared in Harper's Weekly in the 1860's.

Nast was only an average draftsman. But he excelled at inventing concepts for cartoons and at arranging the elements of his designs. In most cases, Nast drew sketches that were given to other artists, who used the sketches to make engravings in blocks of wood. The engravings were used to print the cartoons.

Nast was born in Landau, Bavaria, and came with his mother to the United States in 1846. He worked as a draftsman on Frank Leslie's Illustrated Newspaper and sketched warfare in Italy for New York City, London, and Paris newspapers. Charles P. Green

For other pictures by Thomas Nast, see Carpetbaggers; New York City; and Santa Claus.

Nasturtium, nuh STUR shuhm, is the common name of a group of perennial plants native to tropical America. Nasturtium is a favorite garden flower of North America. There, it is a trailing or climbing annual that may reach about 10 feet (3 meters). Its blossoms are yellow, orange, or red. Dwarf nasturtiums are also grown.

The nasturtium flower has an interesting structure. There are five small sepals (outer 'petals'). The three upper ones form a long spur that holds the nectar. There are also five petals. The three lower petals are a little apart from the upper two and have long, fringed claws. The long-stalked leaves are shaped like an umbrella. They have a spicy taste and are used in salads. The leaves also make an attractive light green background for the bright flowers.

Nasturtiums grow well from seeds sown outdoors in spring. They can also be potted in the early spring and transplanted in May. The plants cannot stand frost, but may be grown indoors in winter. Nasturtiums are easy to grow. They thrive best in bright sunlight. Small insects, called black aphids, often attack the plants and live on the underside of the leaves. The insects will destroy the nasturtium unless they are controlled with an insecticide. The name nasturtium is also given to the genus of the water cress (see Cressi).

Scientific classification. Nasturtiums belong to the nasturtium family, Tropaeolaceae. The scientific name for the garden flower is Tropaeolum majus.

Daniel F. Austin

Natal, nuh TAL, is a historic region on the east coast of South Africa. The region has been the home of Zulu people for centuries. The region's full name is Terra do Natal, which means Land of Christ's Birth in Portuguese. The name was chosen by the Portuguese explorer Vasco da Gama when he sighted the region on Christmas Day, 1497.

Between 1818 and 1828, a Zulu leader named Shaka established a powerful state known as KwaZulu (Zululand) in northern Natal. The southern part of Natal became a British colony in 1843. White settlers opened sugar plantations and encouraged workers to come from India to Natal. In 1879, after two bloody wars between the Zulu and the Natal colonial authorities, Zululand was made part of the British colony of Natal.

The British gave the government of Natal to the white minority in the region even though more Zulu and Indians lived there. In 1910, Natal became one of the four provinces in the new Union of South Africa. The three other provinces were Cape Province, Orange Free State, and Transvaal. In 1994, black people took over the South African government. That same year, South Africa increased the number of its provinces to nine. The Natal area remained a province, but the province's name was changed to KwaZulu-Natal. The province of KwaZulu-Natal covers about 35,000 square miles (91,000 square kilometers). Pietermaritzburg is its capital. The port city of Durban is its largest city.

Bruce Fetter

See also Bantu; Durban; Pietermaritzburg; Zulu.
Natchez, NACH ihz, Mississippi (pop. 18,464), is the oldest city on the Mississippi River. It lies on the state's southwestern border (see Mississippi [political map]).

Jean Baptiste Le Moyne, Sieur de Bienville, a French governor of Louisiana, built Fort Rosalie on the site in 1716. The white settlement around the fort took the name Natchez from a local Indian tribe. In 1729, the Natchez Indians destroyed the fort, but settlement of the area continued. The United Kingdom gained control of the territory in 1763. Spain controlled it from 1779 until it became part of the United States in 1798. The growth of the cotton industry made Natchez Mississippi's center of wealth and culture before the Civil War (1861-1865).

Natchez attracts many tourists because it has the largest concentration of antebellum (pre-Civil War) houses in the nation. The city is also a retail and manufacturing center. Products include lumber, oil, pecans, and rayon pulp. Natchez has a mayor-council government. It is the seat of Adams County.

Natchez Indians, NACH ihz, were a tribe in North America whose chief had total power over their subjects' lives and property. The tribe once lived near the city along the Mississippi River that was named after them. They were farmers, and they made excellent fabrics and pottery. Each tribe member inherited a place in a society of rigid class distinctions. There were three classes of nobility, as well as a large group of common people. The Natchez had a highly developed religious life based on sun worship. They believed that their chief was descended from the sun. Servants carried him about in a special litter, so that his feet would not touch the ground. When an important Natchez chief died, tribe members paid considerable respect to the leader and performed sacrifices.

The name of the Natchez first occurs in the reports of Sieur de La Salle's descent of the Mississippi River in 1682. The tribe, which probably included about 6,000 people, was the largest and strongest on the lower Mississippi at that time. They fought three major wars with the French, but were so soundly defeated in 1729 that the tribe did not recover. The survivors joined other tribes.

Natchez Trace was an important commercial and military route between Nashville, Tennessee, and Natchez, Mississippi, in the early 1800s. Pioneers who floated their goods on flatboats down the Mississippi River to New Orleans often returned on horseback along this route. Settlers moving into Alabama, Florida, Louisiana, Mississippi, or Texas frequently traveled south on the trace. In 1800, Congress made it a post road (mail route). In 1938, the Natchez Trace National Parkway was established.

See also National Park System (table: Parkways).

National is a large group of people united by a common language, ancestry, history, or culture. People often feel great loyalty to their nation and pride in their national characteristics. Such feelings of loyalty and pride are often referred to as nationalism. See Nationalism.

In international law, nation means a group of people exercising self-government within a defined territory with the recognition of other nations. Recognition is shown by other nations through the exchange of ambassadors. When a new nation is recognized by other nations, it acquires certain rights and duties. Its rights include the right to navigate freely on the high seas. Its duties include the obligation not to threaten or use military force against other nations. Sometimes in international law, a nation is called a country or state. For more information on nations as defined in international law, see Country; International law.

Anthony D'Amato

Nation, Carry Amelia Moore (1846-1911), became well known for her violent efforts to stop the sale of alcoholic liquors. Although she was arrested often for disturbing the peace, she impressed many people with her sincerity and courage. Other people considered her intolerant. She carried the temperance crusade from the level of education to that of action, and helped bring on national prohibition, which was adopted in 1919, after her death (see Prohibition).

She was born on Nov. 25, 1846, in Garrard County, Kentucky. In 1867, she was married to Dr. Charles Gloyd, a drunkard who died soon after their marriage. She then taught school and rented rooms. In 1877, she married David Nation, a lawyer and minister. Her strong religious interests intensified, and she began to see visions. Her belief that she was divinely protected increased in 1889, when a fire in her town left her hotel untouched. She thought, too, that her name (Carry A. Nation) had been preordained.

The Nations settled in Kansas in 1889. An 1880 state law banned liquor sales there. But it was not enforced. Carry Nation began in 1890 to pray outside saloons. Later she began to smash them. Nearly 6 feet (183 centimeters) tall and strong, she did much damage, first with stones and other implements, and later with hatchets. She closed the saloons of her own town, Medicine Lodge, and destroyed saloons in the chief Kansas cities. When she entered states where liquor sales were legal, she was often arrested for disturbing the peace.

Carry Nation opposed tobacco, and immodesty in women's dress. She spoke eloquently, and inspired others to imitate her. Her husband divorced her for desertion in 1901.

Louis Filler

Additional resources

Carry Nation holds the weapons that she used in her crusade against alcoholic beverages in the early 1900s. The Bible was her text for many lectures. She used the hatchet often in her violent saloon-wrecking campaign.
**National Aeronautics and Space**

**Nation of Islam** is a religious group in the United States that preaches black nationalism. American minister Louis Farrakhan established the organization in 1977. He based it on the teachings of Elijah Muhammad, who had led a group of the same name from 1934 to 1975. Farrakhan continued Muhammad's teachings about the need for self-knowledge, the acceptance of black identity, and economic independence.

Farrakhan's Nation of Islam is headquartered in Chicago. Its members are urged to eat only one meal a day and to avoid the use of tobacco and alcohol. Women are expected to emphasize housework and child rearing, though some women serve as ministers. The key groups in the organization are the Fruit of Islam and Muslim Girls Training (MGT). Members of the Fruit of Islam provide security in mosques (places of worship) and public places. Members of the MGT learn domestic skills.

The original Nation of Islam (also called Black Muslims) was founded in Detroit in 1930 by a salesman named Wallace D. Fard (also known as Wali Farad). Elijah Muhammad (formerly Elijah Poole) led the group from 1934 until his death in 1975. He taught that Fard was Allah and he himself was Allah's messenger. Muhammad also taught that white people were "devils" who sought to harm and oppress blacks. He said that whites would eventually be destroyed and blacks would emerge victorious.

Muhammad's son Warith Deen Mohammed (sometimes spelled Muhammad) succeeded him. Instead of continuing his father's teachings, Warith dismantled the Nation of Islam. He led his followers to Sunni Islam, a traditional branch of Islam practiced by many Africans. In time, his group became known as the Muslim American Society. Farrakhan and other discontented followers resurrected the Nation of Islam but rejected the name Black Muslims. Farrakhan also stopped preaching that whites would eventually be destroyed.

In 1997, Farrakhan began to move closer to traditional Sunni Islam. He adopted the orthodox Friday worship service, prayer posture, and fasting. These measures helped end 25 years of separation and hostilities between Farrakhan and Mohammed. The two men declared their unity at the second International Islamic Conference in Chicago in February 2000. But they continue to lead separate movements.

---

**National Academy of Sciences (NAS)** promotes research in the behavioral, biological, physical, and social sciences. It also uses these sciences for the general welfare. The NAS serves as a scientific adviser to the United States government but is not a government agency. The NAS consists of about 1,600 scientists elected to the organization in recognition of their achievements in research. Foreign scientists may be elected as foreign associates. A maximum of 60 Americans and 15 foreign associates may be elected annually.

The NAS has created three organizations—the National Research Council, the National Academy of Engineering, and the Institute of Medicine. The National Research Council carries out most of the work of the other organizations. The National Academy of Engineering and the Institute of Medicine elect their own members but cooperate closely with the NAS in advising the government on matters of technology and health.

The National Research Council enables other scientists to work with members of the National Academy of Engineering, the Institute of Medicine, and the NAS. About 10,000 scientists and engineers belong to committees and other groups organized by the council to solve scientific and technological problems. The council is financed by government and private funds.

The National Academy of Engineering consists of engineers who are elected because of professional achievement. The academy has about 700 members.

The Institute of Medicine has over 300 members. They are chosen because of their interest in problems of health and medicine. At least a fourth of the members come from fields other than health and medicine.

Congress established the NAS in 1863. Its charter requires the NAS to provide free advice to the government on scientific matters in addition to engaging in other scientific activities. The NAS established the National Research Council in 1916. The National Academy of Engineering was established in 1964. The Institute of Medicine was founded in 1970. All four groups have headquarters in Washington, D.C.

Critically reviewed by the National Academy of Sciences.

**National Aeronautics and Space Administration (NASA)** is a United States government agency that conducts and coordinates research on flight within and beyond the earth's atmosphere. NASA employs thousands of scientists, engineers, and technicians in 10 major installations. These facilities include the John F. Kennedy Space Center on Merritt Island, Florida, and the Lyndon B. Johnson Space Center in Houston.

NASA was established in 1958, with headquarters in Washington, D.C. It absorbed the National Advisory Committee for Aeronautics. NASA has launched many space flights both with and without astronauts. The flights that carried no crew included artificial satellites and space probes used for scientific research and practical applications, such as communications and weather forecasting. In 1969, NASA's Apollo 11 spacecraft became the first to land human beings on the moon. In 1981, NASA launched Columbia, the first space shuttle.

In 1986, NASA suffered the worst accident in its history. The shuttle Challenger broke apart shortly after launch on January 28. All seven crew members were
killed. NASA resumed space flight in September 1988 with the launch of the redesigned shuttle Discovery.

NASA’s Mars exploration program also had setbacks. Two remotely controlled probers to Mars, the Mars Climate Orbiter and the Mars Polar Lander, were lost in 1999. Two independent panels that investigated the loss blamed each of them on mix-ups and mismanagement. The failures led NASA to postpone the launch of another Mars lander, which had been planned for 2001. NASA also began a detailed review of its Mars exploration plan.

In 1993, the United States and Russia agreed to work toward the construction of what would be called the International Space Station (ISS). In 1995, in the first phase of the ISS project, the shuttle Atlantis docked with the Russian space station Mir. By the late 1990’s, agencies representing 14 other nations had joined NASA and its Russian partners on the project. NASA was to manage the ISS. Completion is scheduled for the early 2000’s.

In 2000, NASA put a probe called the Near Earth Asteroid Rendezvous (NEAR) into orbit around an asteroid named Eros. NEAR was the first spacecraft to orbit an asteroid. Johns Hopkins University in Maryland built the probe and helped manage the mission. Alex Roland

**National Air and Space Museum**, in Washington, D.C., features exhibits on aviation and space flight. It is part of the Smithsonian Institution. The museum has more than 20 galleries, a theater, and a planetarium. The displays include the Wright brothers’ 1903 Flyer; Charles A. Lindbergh’s *Spirit of St. Louis*; X-1 and X-15 aircraft; and Mercury, Gemini, and Apollo spacecraft. Museum visitors may walk through a Skylab space station. Congress created the National Air Museum in 1946 and gave it its present name in 1966. The museum’s present building, on the National Mall, opened in 1976.

Critically reviewed by the National Air and Space Museum

**National Alliance of Business** (NAB) is a nonprofit organization committed to building a quality work force for the United States. The NAB helps private businesses, state and local governments, education organizations, and labor groups form partnerships to improve education, training, and employment programs.

The NAB helps state and local partnerships (1) develop learning programs in the workplace, (2) involve business in the restructuring and reform of public education, and (3) create job-training for unskilled and unemployed individuals. It provides guidance and information on these efforts through publications, conferences, seminars, and an information center.

President Lyndon B. Johnson established the NAB in 1968. The organization has regional offices in Atlanta, Georgia; Chicago; Dallas; Los Angeles; and New Brunswick, New Jersey. Its headquarters are in Washington, D.C. Critically reviewed by the National Alliance of Business

**National anthem** is the official patriotic song of a nation. National anthems are intended to stir a sense of patriotism and loyalty among citizens of a country. They are performed at official and ceremonial public occasions, international gatherings, and athletic events. They are also played to honor a head of state.

Most national anthems are composed as marches, hymns, and anthems. The words of some commemorate the ideals of the nation. Others celebrate a country’s natural beauty or honor a national hero. Some recall a national crisis or important event in a country’s history.

Many countries have adapted existing music and words for their anthems. For example, John Stafford Smith, an English composer, wrote “To Anacreon in Heaven” (late 1700’s). The song became the music for “The Star-Spangled Banner,” the national anthem of the United States. The words of the anthem are a poem written by Francis Scott Key in 1814.

The idea of an official national anthem dates from about 1825. At that time, Britain’s patriotic song “God Save the King” (or “Queen”) was called “the national anthem.” However, the song had been performed as early as 1745 and ranks as the oldest national anthem in the world.

Leonard W. Van Camp

**National Archives**, *AHR kuvz*, is an independent federal agency that preserves and makes available for public use the permanently valuable records of the United States government. Its official name is the National Archives and Records Administration. The archives, established in 1934, include most of the nation’s presidential libraries (see Presidential libraries).

The National Archives takes care of millions of records, including maps, sound recordings, still pictures, and motion pictures. These records date from 1774 to the present. Many of the records are kept in the National Archives Building in Washington, D.C. The temperature and humidity of the building’s 196 stack areas are carefully controlled. Each year, more than a million people visit the stately Exhibition Hall to see such historic documents as the Declaration of Independence

![National Archives](NationalArchives.jpg)

**Exhibition Hall** in the National Archives Building houses such historic documents as the Declaration of Independence and the Constitution of the United States.
and the U.S. Constitution. These charters of America's freedom are sealed in bronze and glass cases filled with helium. They can be lowered at a moment's notice into a fire-resistant and shockproof safe.

**National Assessment of Educational Progress**

is a government program designed to evaluate the quality and progress of education in the United States. It is sometimes referred to as NAEP or "the Nation's Report Card." The program was created by Congress in 1964 and is directed and funded by the U.S. Department of Education's National Center for Education Statistics. NAEP conducted its first evaluation in 1969. Since then, it has issued more than 300 reports. The program's staff surveys students at three age and grade levels: 9-year-olds and 4th-graders, 13-year-olds and 8th-graders, and 17-year-olds and 12th-graders. The assessment presents profiles based on nationally representative samples of these students. The tests cover such areas as art, computer skills, literature, mathematics, music, science, U.S. history, and writing. In 1988, Congress specified that reading and mathematics be assessed every two years, writing and science every four years, and history and geography at least every six years. Educational Testing Service, a private, nonprofit corporation, has administered NAEP since 1983.

Critically reviewed by Educational Testing Service

**National Association for the Advancement of Colored People (NAACP)** is a civil rights organization in the United States. It works to end discrimination against blacks and other minority groups.

The NAACP achieves many goals through legal action. It played an important part in the 1954 ruling of the Supreme Court of the United States that segregation of blacks in public schools is unconstitutional. Thurgood Marshall, a lawyer from the NAACP Legal Defense and Educational Fund, presented the argument in the case, known as *Brown v. Board of Education of Topeka*.

The organization also achieves its goals through legislative action. It played a leading role in obtaining passage of the Civil Rights Act of 1957, which protects the right to vote. This act established the Civil Rights Division of the Department of Justice and the Commission on Civil Rights. The NAACP worked for passage of the Civil Rights Act of 1964, which forbids discrimination in public places. This law established the Equal Employment Opportunity Commission (EEOC). The association also helped bring into law the Voting Rights Act of 1965, which protects voter registration.

**Activities.** The NAACP has worked successfully to fight discrimination in housing and to strengthen the penalties for violations of civil rights. In the 1970's and 1980's, it helped win extensions of the Voting Rights Act of 1965. The NAACP also led successful efforts in 1972 to increase the power of the EEOC. In 1986, the NAACP successfully campaigned for the United States to impose economic sanctions against South Africa because of its system of racial segregation, called apartheid. The NAACP helped obtain passage of an amendment in 1988 that strengthened the Fair Housing Act of 1968.

The organization strives to protect the rights of prison inmates. Its investigation of problems facing black military personnel led to changes in the system of military assignments and promotions. The NAACP sponsors a program of voter education and registration. It works for desegregation of public schools and fights dismissals and demotions of black teachers and administrators that it considers discriminatory. It urges publishers to produce textbooks that provide an accurate account of the achievements and activities of blacks. The NAACP also seeks to reduce the number of students who drop out of school and to encourage and reward academic, scientific, and artistic excellence among black students.

The NAACP also acts to reduce poverty and hunger. In 1968, the organization established the Mississippi Emergency Relief Fund to feed poor blacks in the Mississippi Delta area.

**History.** The NAACP was founded in 1909 by 60 black and white citizens. In 1910, the organization began to publish *Crisis*, a magazine about blacks who have achieved success in the arts, business, and other fields.

During the NAACP's first 30 years, it worked to prevent violence against blacks, unjust legal penalties, and job discrimination. Much of its activity centered on passage and enforcement of antilynching laws. During World War II (1939-1945), the NAACP tried to obtain equal rights for black military personnel and more job opportunities for black civilians. After the war, the association stepped up its long struggle against the policy that treated blacks as "separate but equal." This policy had been established in 1896 by the Supreme Court's ruling in the case of *Plessy v. Ferguson*.

The NAACP has hundreds of thousands of members and hundreds of youth councils. It receives funds from membership fees and from private donations. It has headquarters in Baltimore. It has a legislative bureau in Washington, D.C. The NAACP Legal Defense and Educational Fund, which has been an independent organization since 1957, is headquartered in New York City.

**National Association of Congregational Christian Churches** is a Protestant religious fellowship. It was founded in 1955 by a number of Congregational Christian Churches. It stresses cooperation among member churches but has no authority over them.

The association operates missions, supports students in seminaries, and conducts training programs for ministers. It also sponsors several commissions dealing with various church affairs and publishes a journal called *The Congregationalist*. The association has about 400 churches and about 95,000 members. The national office is in Oak Creek, Wisconsin.

Critically reviewed by the National Association of Congregational Christian Churches

**National Association of Manufacturers (NAM)** is an organization of American manufacturing compa-
nies. It is the largest broad-based manufacturing advocacy (support) group in the United States. It serves as a policymaking body for the manufacturing industry on industrial and economic matters, and other public issues. It also interprets industry's policies to the federal government and the public. The organization's 12,500 member companies produce about 85 percent of U.S. manufactured products.

Representatives from NAM's member companies form policymaking committees that make recommendations to its Board of Directors. The board and an Executive Committee meet several times a year to determine policies. NAM was founded in 1895. It has headquarters in Washington, D.C.

**National Baptist Convention, U.S.A., Inc.** is the largest black religious body in the world and the parent organization for African American Baptists. The convention has a membership of about 7,500,000 with 30,000 churches and almost 30,000 ministers. The convention was organized in 1880. It preaches the Gospel of Jesus Christ and promotes both home and foreign missions. The convention supports Christian education and prints and sells religious literature through its publishing house in Nashville. See also **Baptists**.

Critically reviewed by the National Baptist Convention, U.S.A., Inc.

**National Baptist Convention of America, Inc.** is an organization of black Baptists. It originated with the founding of the Foreign Mission Baptist Convention in 1880. The National Baptist Convention was formed in 1895, when the Foreign Mission Baptist Convention merged with two other Baptist conventions. In 1913, this group split into the National Baptist Convention of America and the National Baptist Convention, U.S.A., Inc. The National Baptist Convention of America, Inc., is an agency of Christian education and missionary work. It combines the efforts of Baptist churches and organizations in missionary activity nationally and internationally. It supports foreign missions in Jamaica, Liberia, and Panama. The convention has about 3 million members.

**National budget** is the financial plan for a nation's government. The budget forecasts the government's income and expenditures for one fiscal year (from October 1 to September 30 in the United States). It forecasts how much money the government will collect from taxes and other sources, and suggests how much money each government department should spend.

In the United States, the Office of Management and Budget prepares the federal budget, and the congressional budget committee reviews and amends it. The government gets most of its income from individual and corporation income taxes and payroll taxes for social insurance. Most government expenditures are for social insurance benefits, national defense, and interest on the national debt (see **National debt**). Thomas F. Dernburg

See also **Budget** (Government budgets); Congressional Budget Office; Management and Budget, Office of; Taxation (illustration: The federal government dollar).

**National Bureau of Economic Research** is a private nonprofit corporation that conducts research on economic issues. It provides universities, professional associations, corporations, and the United States government with information and objective analyses of economic problems. The bureau is not affiliated with any university or government agency, or with any other organization.

The bureau is perhaps best known for its studies of business cycles, the rises and falls in economic activity. For example, it determines when U.S. recessions (periods of reduced economic activity) begin and end. The bureau also researches such matters as international trade, taxation, investment, and labor markets. Other projects deal with private pensions and social security, and with the historical development of the economy.

Researchers at the bureau have developed important statistical methods now used to measure economic performance. For example, they devised ways to estimate national income and studied the rate of capital formation (growth in the stock of machinery, buildings, and other productive goods). Business people, economists, and government officials use these figures to determine economic conditions and to plan for the future.

The National Bureau of Economic Research was founded in 1920. It is governed by a board of directors, which includes industrial leaders, bankers, financial experts, university economists, and accountants. The bureau's offices are located in Cambridge, Massachusetts, New York City, and Palo Alto, California.

**National Catholic Educational Association** is a group that encourages cooperation and mutual helpfulness among Roman Catholic educators, and promotes, by study, conference, and discussion, Catholic educational work in the United States. The group was founded as the Catholic Educational Association in 1904 in St. Louis, Missouri, and, in 1927, became the National Catholic Educational Association. Its work is carried on by a Parents Organizations Commission and various departments. These departments are the Boards of Education, Chief Administrators of Catholic Education, College and University, Elementary School, Religious Education, Secondary School, Seminaries, and Special Education. The organization has about 14,500 members. Its headquarters are located in Washington, D.C.

Critically reviewed by the National Catholic Educational Association

**National cemetery** is a burial place for men and women who served in the armed forces of the United States. Veterans are eligible to be buried in a national cemetery unless they received a dishonorable discharge. In addition, the spouses and dependent children of these veterans may be buried in national cemeteries. The government maintains about 130 national cemeteries throughout the United States and Puerto Rico. More than 50 of them have no space for additional graves. Almost 2 million people are buried in national cemeteries.

Four government agencies operate the national cemeteries. The Department of Veterans Affairs maintains 114 of the cemeteries. The National Park Service is responsible for 14 national cemeteries that are part of historic sites. The Department of the Army operates 2
cemetery—Arlington National Cemetery in Arlington, Virginia, and Soldiers Home National Cemetery in Washington, D.C. The American Battle Monuments Commission maintains all U.S. military cemeteries outside the United States and its possessions. The Department of Veterans Affairs provides headstones and markers for all graves in national cemeteries and for all graves of veterans that do not have them. These graves include those of Civil War soldiers.

The national cemetery system was established in 1862, during the American Civil War. That year, Congress granted President Abraham Lincoln permission to establish cemeteries for Union Army veterans.

One of the best-known national cemeteries operated by the National Park Service is in Gettysburg, Pennsylvania. A crucial Civil War battle was fought in Gettysburg in July 1863. On November 19 that year, Lincoln delivered his Gettysburg Address at a ceremony dedicating part of the battlefield as a cemetery. The other historic cemeteries operated by the National Park Service are Andersonville in Georgia; Andrew Johnson, Fort Donelson, Pittsburg Landing, and Stones River in Tennessee; Antietam in Maryland; Battleground in Washington, D.C.; Chalmette in Louisiana; Custer at Little Bighorn Battlefield National Monument in Montana; Fredericksburg, Poplar Grove, and Yorktown in Virginia; and Vicksburg in Mississippi.

See also American Battle Monuments Commission; Arlington National Cemetery; Little Bighorn Battlefield National Monument.

National Collegiate Athletic Association (NCAA) is an organization that establishes athletic standards and official playing rules for college sports. It conducts 81 national collegiate championships in 19 sports for men and 17 sports for women and keeps the official national statistics and records of selected college sports. In addition, the association conducts studies on issues in athletics, and it maintains a large film and video library covering play in championship events. The association also sponsors a postgraduate scholarship program and a degree-completion program for student-athletes who have exhausted their intercollegiate athletics eligibility.

The NCAA was founded in 1906. The association’s membership has grown from 13 schools to over 1,000, including colleges and universities, athletic conferences, and coaches’ associations. The headquarters of the NCAA are in Indianapolis.

Critically reviewed by the National Collegiate Athletic Association

National Conference of Christians and Jews is a nonprofit human relations organization engaged in a nationwide program to eliminate prejudice and discrimination and to promote religious, social, and ethical participation in American society. The conference works to foster understanding among all ethnic, racial, and religious groups. The organization’s educational program includes creative dialogues, institutes, seminars, workshops, and camps.

The National Conference of Christians and Jews works with teachers, parents, young people, police, clergy, business, labor, and community leaders. It sponsors Brotherhood/Sisterhood Week (see Brotherhood/Sisterhood Week). The conference was founded in 1927.

Its headquarters are in New York City.

Critically reviewed by the National Conference of Christians and Jews

National Congress of American Indians is the oldest, largest, and most representative national American Indian organization in the United States. It represents about 250 tribes and has more than 750,000 individual members.

The NCAI is organized as a representative congress to reach agreement on important national issues. It evaluates and monitors government policies on Indian affairs and promotes government initiatives and programs to improve the economic well-being, educational opportunities, and health of American Indians and Alaskan natives. The NCAI works to persuade members of the U.S. Congress to support legislation that benefits Native Americans.

The NCAI is governed by a president and an executive council, which consists of members democratically elected from 12 geographic areas of the United States. The organization operates under the leadership of an executive director. The NCAI publishes the Sentinel, a bimonthly newsletter.

The NCAI was founded in 1944. Its national office is in Washington, D.C.

Leon F. Cook

National Congress of Parents and Teachers is a volunteer organization that unifies the forces of home, school, and community to promote the education, health, and safety of children. The National Congress is commonly called the National PTA. Local units of the organization, known as Parent-Teacher Associations (PTAs), operate in individual schools from the elementary to the high school level and in other community locations. In many high schools, the local groups are called Parent-Teacher-Student Associations (PTSA's) because students also take part in their activities. PTAs and PTSA's urge their members to become fully informed about education and to take an active interest in school programs. The units conduct regularly scheduled meetings and organize workshops and community service programs to benefit children, teen-agers, and families.

PTA's and PTSA's design their programs to fit both their own needs and the goals of the National PTA. One of the National PTA's goals is to provide students with the best possible mental and physical education. The group also calls for adequate laws to protect children and young people. In addition, the PTA promotes the welfare of youth in the community, home, and school.

The National PTA conducts programs at the national, state, and local levels. At the national level, projects have dealt with parent education and the prevention of alcohol and drug abuse. The National PTA issues an award-winning magazine, PTA Today, as well as planning kits, videos, and pamphlets for use by local units.

State branches of the National PTA are located in all 50 states, in Washington, D.C., and in Europe and Japan for U.S. military personnel in those countries. Membership in local units is open to anyone who wants to help the association achieve its goals. A person who joins a local PTA or PTSA automatically becomes a member of the state branch and the national organization.

The National Congress of Parents and Teachers was founded as the National Congress of Mothers in 1897. State branches were organized the same year. The organization has more than 7 million members. The
group’s headquarters are located in Chicago.

**National Consumers League** is an organization founded in 1899 to develop a sense of responsibility for the promotion of safety, health, and economic welfare of consumers and workers. The league worked for child labor laws, the elimination of sweatshops, the 8-hour day for women, social insurance, and national health insurance for the elderly under Social Security. The league introduced the idea of minimum wage laws in the United States. It also worked for the establishment of the Food and Drug Administration, meat inspection, and other consumer protection legislation.

Today, the National Consumers League works to promote affordable health care, awareness of hazardous chemicals used in jobs and in the community, food and drug safety, fair tax policies, child labor laws, and consumer protection. Its headquarters are in Washington, D.C.

Critically reviewed by the National Consumers League

**National Council of Churches** is an organization of 32 United States Protestant and Orthodox denominations with a combined membership of 42 million. Its members promote Christian unity, working together on programs that serve the churches and wider society. Much of the council’s work is done overseas. It includes disaster relief and refugee assistance. The council carries out many ministries, including education, social justice, theological dialogue, and interfaith relations.

A 270-member governing board meets twice a year to set council policy. A little over half its members are clergy of member churches. The others are lay leaders.

The council was formed in 1950 by 29 member denominations and through the merger of 14 interdenominational agencies. Its full name is the National Council of the Churches of Christ in the U.S.A. The council publishes a monthly newsletter called *Ecu-Link*. Headquarters are in New York City.

Critically reviewed by the National Council of Churches

**National Council of La Raza** is an organization that aims to improve life opportunities for Hispanic Americans. The council addresses such issues as poverty, discrimination, health, and education. It is the largest Hispanic organization in the United States, serving Hispanic nationality groups in all parts of the country. The organization began in 1968.

The National Council of La Raza uses two main approaches to meet its goals. First, it provides capacity-building assistance to community-based Hispanic organizations. Its help in management, programming, and resource development enables smaller programs to reach greater numbers of people. Second, the council conducts research and analysis on matters of government policy and public concern. It publishes many materials and holds frequent media activities to raise awareness of Hispanic issues.

The organization takes its name from the writings of Mexican scholar José Vasconcelos. Vasconcelos originally used the term *La Raza Cósmica*, which roughly translates into English as *The Cosmic People*. The phrase reflects the diversity of races and cultures in the Hispanic community.

**National Council of Senior Citizens (NCSC)** is a nonprofit organization that advances the interests of older people in the United States. The NCSC consists of more than 5,000 senior citizen clubs throughout the country. They have about 5 million members.

National Council of Senior Citizens is a nonprofit group that supports the interests of older Americans. *Here*, members are protesting a government proposal to reduce retirement benefits.

The NCSC sponsors housing, community service jobs, and other programs for the aged. It calls for improvements in nursing homes and in the funding for Social Security and health care. In addition, the NCSC supports legislation of general concern, such as antipollution laws. The local clubs help senior citizens with problems, provide social and recreational activities, and sponsor community service projects.

The NCSC was founded in 1961. Its national offices are in Washington, D.C.

**National debt** is the total amount that the federal government owes because of money it has borrowed by selling bonds or other securities. In Canada, this debt is commonly known as the **federal government debt**. The national debt exists because the government’s expenses frequently exceed its income from taxes. In such situations, the government sells bonds to get the extra money that it needs. The government must repay the amount of the bonds on a specified date. In addition, it must pay interest on this indebtedness.

Government debt differs from private debt because the government is not required to post any collateral (pledge of security) to guarantee payment of a loan. However, the United States government has always repaid its loans.

**Causes of national debt.** The United States debt originated in the 1790’s, when the newly established federal government assumed debts that the individual states had run up during the Revolutionary War in America (1775-1783). Until the 1980’s, wars were by far the most common cause of increases in the United States national debt. For example, the federal debt was only $1 billion before World War I (1914-1918). The war raised it to about $25 billion. By the end of World War II
in 1945, the national debt had risen to about $259 billion.

The Korean War in the early 1950's and the Vietnam War in the 1960's and early 1970's caused it to rise sharply again. Between 1980 and 1985, major reductions in taxes and increases in defense spending also contributed to a sharp rise in the debt. By 2000, the U.S. national debt was more than $5 trillion.

Wars have also been responsible for high national debts in other countries. In 1867, the newly formed Dominion of Canada assumed the Canadian debt of $93 million. After increases caused chiefly by Canada's participation in two world wars, the debt totaled about $19 billion in the mid-1940's. By 2000, the Canadian national debt had risen to about $650 billion.

Public improvements also increase the national debt. These include such long-lasting improvements as canals, highways, and dams. Some of these public works yield enough income to pay the principal and interest on the bonds issued to finance them. Other projects, such as roads, benefit the nation but generally do not yield income.

United States gross national debt and economic growth since the Civil War (1861-1865)
The gross national debt of the United States is nearly 2,200 times as large today as it was in 1865. But the U.S. population is only about 8 times as large. As a result, the debt per person is about 270 times as great as it was in 1865. In 1945, the year World War II ended, the national debt exceeded the U.S. gross domestic product (GDP). The GDP is the total value of goods and services produced within a country in a year.

Today, the debt is nearly three-fifths of the GDP.

Ownership of the debt. About a fourth of the national debt is held by government agencies. However, banks and private individuals are the largest owners of the debt. Banks and insurance companies buy government bonds as a safe investment and to earn interest on funds not used for other purposes. Individuals also buy bonds for family security and for patriotic reasons. During World War II, millions of Americans bought war bonds. In addition, businesses buy government bonds when they have extra cash that they wish to keep in a safe place while it earns interest. For those who wish to invest for a short time only, the government issues securities known as Treasury bills that mature after 13, 26, or 52 weeks. These securities must be repaid out of income from taxes or from sales of newly issued bills to other investors. Banks and businesses buy most Treasury bills.

Debt policy. It is important to consider the national debt in relation to the nation's total economic strength. One way of doing this is to compare the national debt to the gross domestic product (GDP). The GDP is the total...
value of goods and services produced within a country in a year. For example, the United States national debt rose from about $259 billion in 1945 to about $5 \frac{1}{2} trillion in 2000. But the 1945 debt amounted to 122 percent of that year's GDP, while the 2000 debt was only about 62 percent of the 2000 GDP.

Some people argue that, just as in a family or business, federal government spending should be kept equal to or below its income. Others declare that this comparison is misleading. They point out that, except for the small portion of the debt held by people in other countries, the debt's size is not as important as the effects that increasing or reducing the debt might have on the economy. Both groups usually agree that taxes in prosperous times should be high enough to cover government spending and to reduce the debt.

Those who call for a balanced budget would not favor measures that would increase the national debt if a recession occurred or threatened to occur. But members of the second group would urge government borrowing to pay for public improvements as a sound way to prevent or end recession. They believe it is the government's responsibility to take such action to stimulate business activity, thereby creating more jobs to reduce unemployment.

National defense. See Defense, Department of; Government (Defense); Homeland Security, Office of. National Defense Education Act (NDEA) is a law enacted by the United States Congress in 1958. It was one of the most significant education bills in U.S. history. The NDEA provides financial aid to states, educational institutions, and individuals to improve educational programs in the United States.

The NDEA provides federal loans to students who show financial need. Students working on bachelor's degrees may borrow money for their education. NDEA also will lend money for vocational education. Repayment begins after the student leaves school. The borrower has a number of years to repay the loan but must pay a certain amount every month. A borrower who enters certain fields of teaching or teaches in certain schools may have part of the debt canceled.

The NDEA also provides funds for states to buy teaching equipment in science, mathematics, language, English, reading, history, civics, and geography. Private schools also can borrow money for this purpose. Other NDEA programs include graduate fellowships, research into the use of communications media for educational purposes, the improvement of counseling and testing programs, expanded teacher-training programs in critical subjects, and the improvement of vocational education. States must match federal funds in order to get NDEA funds. The NDEA is administered by the United States Department of Education.

Douglas Sloan

National Education Association of the United States (NEA) is the largest professional education organization in the world. The NEA has more than 2 million members, most of whom are teachers. The organization's main goals include improving public education and classroom conditions in the United States, and increasing the salaries and benefits of school employees. It works toward these goals through professional activities, judicial and legislative efforts, and collective bargaining. In 1979, the NEA was instrumental in the creation of the U.S. Department of Education.

The NEA has affiliates in every state and in Puerto Rico. It also represents U.S. citizens who teach overseas. Delegates from state and local associations meet annually in a Representative Assembly to establish the NEA's policies. A board of directors and an executive committee act for the NEA between the assembly's sessions.

The history of the NEA can be traced back to 1857, when 43 leaders from state teachers' associations organized the National Teachers Association. In 1870, this group merged with the Association of School Superintendents and the American Normal School Association to form the National Educational Association. For many years, school administrators provided much of the NEA leadership. However, by the mid-1960's, classroom teachers held almost all offices in the NEA. The NEA re-
quires that teachers make up at least 75 percent of the members of each committee. The NEA also has a program for college students preparing for careers in education.

The NEA publishes a number of periodicals, including *NEA Today*, a monthly newspaper. It also publishes books, filmstrips, and leaflets, and materials for American Education Week. The NEA's headquarters are at 1201 16th Street NW, Washington, DC 20036.

**National Farmers Organization (NFO)** is an organization set up by farmers and ranchers to negotiate prices and other terms of sale for their commodities (products). The NFO's main form of negotiation is collective bargaining, in which it negotiates on behalf of many farmers and ranchers at once.

The NFO also uses risk management techniques to decrease the chance that its members will lose money. In one such technique, called forward contracting, the buyer signs a contract to pay a certain price for an agricultural commodity. The agreement occurs well before the commodity is actually produced. Forward contracting protects the farmer against loss if the market price of the product falls after the contract is signed.

The NFO collects payments from buyers and distributes shares of the money to its members. In addition, the organization provides reserve funds to protect members in case a buyer does not pay. The NFO also checks the credit quality of potential buyers.

The National Farmers Organization was set up in 1955. National headquarters are in Ames, Iowa.

**National forest** is an area set aside by the United States Congress to be protected and managed by the federal government. The Forest Service, a part of the Department of Agriculture, manages 156 national forests in the United States and Puerto Rico. These forests cover an area of about 180 million acres (73 million hectares), nearly as large as the states of California and Nevada combined. Many of the forests are named for Indian tribes or for famous people in American history.

**Uses.** Originally, the national forests served primarily as a source of timber and water. Today, the Forest Service manages these areas, along with the country's national grasslands, to maintain a continuous supply of a wide variety of resources. These resources include wood, water, and such minerals as lead and uranium; grazing land for cattle and sheep; and recreational areas. The lands also serve as a home for wildlife. The national forests and grasslands together have nearly 60 percent of the wildlife in the nation.

Managing the national forests is difficult because of their many competing uses. Through public involvement, partnerships linking the Forest Service with environmental and industry groups, and volun-

teer programs, citizens can participate in caring for and managing these areas.

Administration. A forest supervisor administers each national forest. The forests are divided into ranger districts, each headed by a district ranger. A ranger's first duty is to manage all forest uses and services. These include production of wood, water, forage, wildlife, and resources for outdoor recreation. The ranger is also responsible for protecting the forests from such threats as fire, harmful insects, and disease.

United States national forests are grouped into nine regions. Regional foresters head each region. They direct the work of the forest supervisors in their regions. The regional foresters, in turn, report to the chief of the Forest Service in Washington, D.C.

History. Early settlers in the United States adopted the first conservation laws. Nevertheless, destruction of forests became widespread during the settlement of the United States. In 1891, Congress established the first national forest-conservation policy. In that year, Congress authorized the president to set aside areas known as forest reserves. The first one was established in Wyoming. In 1907, the name was changed to national forests.

National Foundation-March of Dimes. See March of Dimes Birth Defects Foundation.

National Foundation on the Arts and the Humanities is an independent agency of the federal government. The foundation develops and promotes a national policy of support for the humanities and the arts.

The foundation is administered by a National Endowment for the Arts and a National Endowment for the Humanities. Each endowment is guided by a council composed of 26 private citizens distinguished for their knowledge and experience in the two allied cultural areas, the arts and the humanities. A Federal Council on the Arts and the Humanities coordinates the foundation's activities with related federal agencies.

The Arts Endowment is authorized to assist individuals and nonprofit organizations in a wide range of artistic endeavors. Additional funds are authorized to aid activities in the arts that are sponsored by the states. The Humanities Endowment also makes grants to its state councils. It directly supports projects in education, public programs, preservation, research, and scholarship in the humanities.

Each endowment is headed by a chairperson, who serves on the federal council, along with representatives of federal agencies whose programs are related to the arts and humanities. The foundation was established in 1965. It is located in Washington, D.C.

National Gallery of Art, in Washington, D.C., is one of the world's leading art museums. Its collections begin with works from the 1100's and represent some of the Western world's greatest achievements in painting, sculpture, and the graphic arts. The collections are especially rich in European Old Master paintings and American, British, French, Italian, and Spanish paintings of the 1700's and 1800's. The museum also displays sculptures from the late 1100's to the present, medals and bronzes from the early 1400's to the early 1900's, and porcelain from China. In addition, it has over 75,000 works of graphic art from the 1100's to the present.

The National Gallery of Art was established in 1937, when American financier Andrew W. Mellon gave most of his magnificent art collection to the government. He also provided money to construct the museum's original building, now called the West Building. American architect John Russell Pope designed the marble neoclassical structure. It opened in 1941. The East Building, designed by Chinese American architect I. M. Pei, was completed in 1978. It houses the museum's growing collection of art from the 1900's. It also includes offices, a library, a sculpture garden, space for temporary exhibitions, and the Center for Advanced Studies in the Visual Arts.

All the works in the gallery have been donated or bought with private funds. Major donations include the collections of Samuel H. Kress, Rush H. Kress, Joseph Widener, Chester Dale, Ailsa Mellon Bruce, Lessing J. Rosenwald, Edgar William and Bernice Chrysler Garbisch, Paul Mellon, and the Mark Rothko Foundation.

The National Gallery of Art is affiliated with the Smithsonian Institution, but it is governed by its own board of trustees. The museum receives operating funds from Congress.

National Gallery of Canada, in Ottawa, Ontario, exhibits the most important collection of Canadian art in Canada. The gallery also has important collections of American, Asian, and European art. It houses more than 40,000 works, including paintings, sculptures, prints, drawings, photographs, videotapes, and films.

Major donations to the gallery include the Massey Collection of English Painting, the Henry Birks Collection of Canadian Silver, the Bronfman Gift of Drawings, and the Heerameneck Collection of Southeast Asian Art. The gallery also includes a fine arts reference library. In addition, the gallery provides guided tours and lectures on its collections and exhibitions.

The National Gallery was founded in 1880 to display a collection of works by members of the Royal Canadian Academy of Arts. Before moving to its present location, the gallery had been housed at a series of temporary sites, none of which was designed for the gallery's special needs. Today, the gallery is housed in a three-story building designed by Moshe Safdie, located in the nation's capital's southwest quadrant.
The National Gallery of Canada, in Ottawa, occupies a modern building designed by Canadian architect Moshe Safdie.

The building is of stainless steel, glass, and rose-colored granite. This building, designed by the Israeli-born Canadian architect Moshe Safdie, opened in 1988.

National Geographic Society is the world's largest nonprofit scientific and educational organization. It was formed in 1888 to gather and spread geographic information throughout the world. It has more than 10 million members in approximately 185 countries. The society has supported and sponsored more than 4,000 expeditions and research projects.

The society distributes information through National Geographic Magazine, a monthly journal; National Geographic World, a magazine for children; Research and Exploration, a scholarly research journal; National Geographic Traveler, a travel magazine; authoritative books; and an information service for the press, radio, and television. It produces atlases, globes, maps, filmstrips, computer and videodisc programs for schools, and television programs. The society also sponsors a program to train geography teachers and promote the teaching of geography to classrooms.

Among the projects the National Geographic Society has helped sponsor are the historic polar expeditions by Richard E. Byrd and Robert E. Peary. The society also helped back the first successful United States expedition to the top of Mount Everest and aided in the discovery of the wreckage of the sunken Titanic. It also sponsored excavations in east Africa that uncovered fossils of primitive human beings who lived about 2 million years ago. The National Geographic Society's headquarters are located in Washington, D.C.

Critically reviewed by the National Geographic Society

National Guard is one of the organizations of the United States Army and Air Force. An outgrowth of the volunteer militia that was first authorized in 1792, the National Guard is a reserve group. Other civilian reserves, such as the Army, Air Force, and naval reserves, have no connection with the National Guard.

Each state, each territory, and the District of Columbia has its own National Guard. The National Guard Bureau of the Department of the Army directs Army units. The Department of the Air Force supervises Air National Guard units. About 350,000 men and women serve in Army units of the National Guard. About 110,000 serve in the Air National Guard.

Members of the National Guard enlist voluntarily and are formed into distinctive units. The Army and Air Force supervise the training of the National Guard. State funds provide armories and other storage facilities. Federal funds provide clothing, weapons, and equipment.

During peacetime, National Guard personnel attend one weekend of training each month. They also receive two weeks of field training every year. The federal government pays them for the time they spend training. About 80,000 members serve full-time to help organize, administer, recruit, and train the National Guard.

Guard members have a dual status because they take an oath of allegiance to their state and to the federal government. Until 1903, the state controlled the militia units. The President had to call units into federal service through the governors of the states (see Militia). The National Defense Acts of 1920 and 1933 extended federal authority. Since that time, the President may order units to active duty for up to two years upon declaring a national emergency, or for up to six months without declaring a national emergency. State governors may order units to active duty during emergencies, such as strikes, riots, and disasters.

National income is the total of all income earned in a nation during a specific period, usually a year. This figure shows whether a nation's economy is growing or declining. Economists use national income figures to compare the economies of various nations.

Determining national income. Economists calculate national income in either of two ways. One way is based on what individuals and businesses earn. The other is based on the production of goods and services. Each method provides the same national income figure because the amount that people earn equals the value of the goods and services produced.
United States national income

National income has risen sharply since the depression of the 1930s. This graph shows how much of the rise comes from the income of employees, the income of businesses, and interest and rent.

National income based on earnings includes all the income earned in a nation during a certain period. This income consists of wages and salaries, interest, profits, and rents.

To find national income based on production, economists first determine a nation's gross national product. This figure represents the total value of the goods and services produced by a nation during a specific period. Economists find the national income by subtracting depreciation and indirect business taxes from the gross national product. Depreciation includes the normal decline in the value of buildings and machinery as a result of doing business. Indirect business taxes are paid by buyers of goods and include sales and excise taxes. The difference between gross national product and depreciation is called the net national product.

National income may be affected by both inflation (rising prices) and deflation (falling prices). For example, if the amount people earn increases 10 percent in one year, the national income figure for that year will rise 10 percent. But if prices also rise 10 percent, people will not be able to buy any more goods or services than they did during the year before. Thus, the national income figure is 10 percent higher because of inflation, not because of economic growth.

In order to compare national income figures for two or more years, economists adjust the national income to include inflation or deflation. The adjusted figure is called real national income.

Importance of national income. National income figures show the rate at which a nation's economy changes. These figures also show the stability of the economy. For example, the economy may be unstable if national income varies greatly from year to year. National income figures also show how income is distributed in the forms of wages, interest, profits, and rent. In the United States, wages, salaries, and employee benefits account for about 70 percent of the national income. Interest, profits, and rent provide the rest of the national income.

Both government and industry adjust their budgets in terms of the level, distribution, and rate of change in national income. If national income falls, for example, the government might decrease taxes in order to allow people more after-tax income to spend. If people spent this additional income on goods and services, business activity would rise. As a result, more jobs would be created, and national income would increase.

National income figures include only payments and losses for which records are kept. As a result, these figures do not fully show the level of a nation's well-being. A homemaker receives no salary for doing housework, and so his or her work does not raise the national income. On the other hand, environmental pollution causes great economic loss. But no one knows the total cost of this loss, and so economists cannot subtract it from the national income.

Changes in national income. National income varies, depending on the efforts of workers, the level of employment, and the quality and quantity of fixed capital. Fixed capital includes the buildings and machinery used to provide goods and services. Improvements in fixed capital may create more jobs and raise the national income. National income in the United States has generally risen from year to year. It has increased mainly because of additions to fixed capital, growth of the labor
force, and improvements in the efficiency of both capital and labor.

National Institute for Occupational Safety and Health (NIOSH) is an agency of the United States Department of Health and Human Services. The institute's investigators study working conditions to determine the causes of employee illness and accidents. These investigations are often conducted at the request of employees or employers. NIOSH also recommends standards to control hazards on the job. It reports its findings to the Occupational Safety and Health Administration (OSHA), which establishes and enforces the standards.

NIOSH submits recommended standards that are determined by studies of worker exposure to dangerous chemicals or radiation, excessive noise, and other conditions on the job. The agency also examines existing health and safety policies in factories and businesses and develops methods to evaluate job hazards. Its duties also include approving respirators and other personal safety equipment and providing job safety and health training for employers and employees. NIOSH was created by the Occupational Safety and Health Act of 1970.

National Institute of Standards and Technology is an agency of the United States Department of Commerce. The institute, often called NIST, develops measurement standards and techniques for American science and industry and for other government agencies. NIST also helps U.S. companies adopt new technologies to increase their international competitiveness.

The institute works to maintain, improve, and apply fundamental systems of measurement, including those of length, time, and mass. It compares and coordinates its measurement standards with those of other countries by working with international agencies. Although the institute has no regulatory authority, it helps private organizations promote the establishment of voluntary standards for commerce and industry.

NIST provides research and technical services in such areas as computer science and technology, materials science, building and fire safety, electronics, and automated manufacturing. Published information on the agency's research can be obtained from the National Technical Information Service of the Department of Commerce.

NIST was established as the National Bureau of Standards in 1901 and became part of the Department of Commerce in 1903. The agency received its present name in 1988.

National Institutes of Health (NIH) is an agency of the United States government. It is part of the Public Health Service of the Department of Health and Human Services. NIH conducts and supports a broad range of biomedical research and provides funds for the training of research scientists. It also classifies and distributes biological and medical information.

NIH conducts research at its laboratories in Bethesda, Maryland. There are 18 NIH institutes. They deal with (1) aging; (2) alcoholism; (3) allergy and infectious diseases; (4) arthritis and musculoskeletal and skin diseases; (5) cancer; (6) child health and human development; (7) deafness and other communication disorders; (8) dental research; (9) diabetes and digestive and kidney diseases; (10) drug abuse; (11) environmental health sciences; (12) the eye; (13) general medical sciences; (14) the heart, lungs, and blood; (15) human genes; (16) mental health; (17) nursing; and (18) neurological disorders and stroke. The Magnuson Clinical Center, a research hospital, serves the institutes. NIH also includes the National Library of Medicine; the Fogarty International Center for Advanced Study in the Health Sciences; the Center for Complementary and Alternative Medicine, and three support divisions that deal with information technology, research resources, and scientific review.

NIH traces its history to 1887, when the Hygienic Laboratory was set up at the U.S. Marine Hospital on Staten Island. The agency adopted its present name in 1948.

Critically reviewed by the National Institutes of Health

National Labor Relations Act, usually called the Wagner Act, is a law that guarantees the right of workers in the United States to form unions. It also ensures the right of employees to engage in collective bargaining—that is, to negotiate as a group with employers about wages, hours, and working conditions.

The rights of workers were originally protected by the National Industrial Recovery Act (NIRA) of 1933, which the Supreme Court declared unconstitutional in 1935. The Wagner Act was passed later that year to reaffirm those rights. Its main sponsor was Senator Robert F. Wagner, a New York Democrat.

The Wagner Act bans certain practices by employers. For example, it prohibits them from interfering with union efforts to bring workers into unions. The act also requires employers to negotiate with representatives elected by workers. The act established the National Labor Relations Board (NLRB) to enforce such provisions (see National Labor Relations Board).

The Wagner Act enables employees of individual companies to decide which union or person will negotiate for them. A worker or employer may request the NLRB to conduct an election among the workers to choose a representative. The employer must then bargain only with the elected representative.

Many employers believed the Wagner Act gave unions too much power. They complained that it allowed unions to force a business to hire only union members. Such a business is called a closed shop. The Taft-Hartley Act of 1947 amended the Wagner Act and outlawed some union activities.  
James C. Scoville

See also New Deal; Taft-Hartley Act.

National Labor Relations Board (NLRB) was created as an independent agency by Congress in 1935 to administer the National Labor Relations Act, often called the Wagner Act. The NLRB works to correct or prevent unfair labor practices committed by either employers or unions. When a union represents 30 percent or more of a group of employees covered by the National Labor Relations Act, the NLRB conducts secret-ballot elections to determine whether employees wish to be represented in collective bargaining.
The president of the United States appoints the five board members and the general counsel, with the consent of the Senate. Each board member serves a five-year term. The general counsel has a four-year term. The NLRB’s main offices are located in Washington, D.C. Petitions for elections and charges of unfair labor practices are filed at regional offices. James G. Scoville

See also Industrial relations; National Labor Relations Act.

**National laboratory** is any one of nine major scientific laboratories owned and supervised by the United States Department of Energy. The laboratories do work for that department and for other federal agencies, such as the Department of Defense, National Research Council, and Environmental Protection Agency. Activities at the laboratories range from fundamental research intended to provide a better understanding of the universe to applied programs in national security, energy, and conservation. Research at the facilities has led to advances in such areas as nuclear power and nuclear medicine. Today, the laboratories are also studying human genetics, superconducting materials, fusion energy, global environmental change, and computers. In addition, the laboratories conduct programs for students and teachers to improve science education at all levels.

The national laboratories are operated by employees on contract from universities and private industries. Physicists, chemists, engineers, and environmental scientists often work as a team to pursue the solution to scientific problems. University faculty and students and industrial scientists also often work with the scientists at the laboratories.

Some of the laboratories developed as nuclear research centers during World War II (1939-1945). For example, a team of scientists created the first controlled, self-sustaining nuclear chain reaction at the University of Chicago in 1942. A few months later, the scientists moved the experiment to a site that was to become Argonne National Laboratory.

**National League.** See Baseball (Major leagues; Professional baseball).

**National League of Cities** is the largest organization that represents United States cities. Membership is open to all cities and state federations of cities.

The league works to improve the quality of life for people who live in cities and to strengthen local government. Its officials discuss urban problems with members of Congress, officials in the executive branch, and other leaders to win support for a national urban policy. The organization sometimes takes legal action in federal courts on matters involving cities. It publishes a weekly newspaper called *Nation’s Cities Weekly* and various reports on city policies and procedures. The league holds an annual convention called the Congress of Cities that is attended by mayors, city managers, council members, and other city officials. At this meeting, league members review, amend, and approve the organization’s national municipal policy.

The history of the league dates back to 1924, when leaders of 10 state federations of cities formed the American Municipal Association. The organization changed its name to the National League of Cities in 1964. Its headquarters are in Washington, D.C.

**National Library of Canada.** See Library (Canadian government libraries).

**National Library of Medicine.** See Library (Government libraries).

**National Mediation Board** is a United States government agency that administers the Railway Labor Act. This law, enacted in 1926, governs labor-management relations in the railroad and airline industries. The board’s two main functions are (1) to ensure the right of employees to organize into free and independent labor organizations, and (2) to help settle disputes over wages, rules, and working conditions.

In a dispute, either side may ask the board to mediate by suggesting solutions. The board may also enter the dispute without invitation. If mediation fails, the board asks the two sides to accept voluntary arbitration. If the parties agree, the board appoints a referee, whose decision is binding. If the parties refuse to arbitrate, the board formally notifies them that it has not been able to settle the dispute. A 30-day cooling-off period then follows while the board tries to settle the dispute. If an agreement is not reached by the end of this period, the parties are free to act on their own. As a last resort, the president of the United States may establish an emergency board to help end the dispute.

Congress created the board in 1934. It has three members, who are appointed by the president subject to the approval of the Senate.

**National Medical Association (NMA)** is a professional organization that represents the interests of African American physicians. It was founded in 1895. The NMA is dedicated to ensuring that all career paths in the field of health care are open to African American physicians; that African Americans are well represented in the medical and health professions; and that quality health care is available and accessible to all patients, regardless of their ability to pay. The NMA publishes periodic reports and the *Journal of the National Medical Association*, a monthly scientific journal. The association also holds an annual convention. It has national headquarters in Washington, D.C.

**National Motto, United States, is In God We Trust.** Congress made this phrase the official motto of the United States in 1956. It has appeared on coins since 1864, and probably originated from verse 4 of "The Star-Spangled Banner": "And this be our motto: In God is our trust." See also E Pluribus Unum.

**National Museum of African Art,** a bureau of the Smithsonian Institution in Washington, D.C., features the
The National Museum of Natural History in Washington, D.C., is a world center for the study of the natural sciences. The museum’s Discovery Center offers an Immersion Cinema experience, shown here, which allows museum visitors seated at touch-screen monitors to interact with an on-screen narrative.

National Museum of Natural History ranks as one of the world’s major centers for the study of the natural sciences. The museum consists of the United States government’s collections of items relating to human beings, the earth and its environment, and outer space. In addition, the museum carries on educational and research work. It is in Washington, D.C.

Research conducted at the museum contributes to the advancement of medical knowledge, agricultural and mineral production, and environmental conservation. The museum houses exhibits on such subjects as the cultures of the Americas, the Pacific, Africa, and Asia; the evolution of human beings; dinosaurs and other fossils; and the ice age. The museum also has displays of gems and minerals, moon rocks, meteorites, mammals, birds, and marine life. Special features at the museum include a live insect zoo, a living coral reef, a naturalist center, and a “discovery room” where people of all ages can handle natural history specimens.

The museum is a branch of the Smithsonian Institution, which was founded in 1846. The American naturalist Spencer F. Baird began to develop the natural history collections during the 1850’s. The collections have grown to more than 119 million items. The National Museum of Natural History is supported largely by annual grants from Congress.

National Naval Medical Center, in Bethesda, Maryland, is the largest United States Navy facility for medical care, research, and training. It covers 242 acres (98 hectares) about 10 miles (16 kilometers) northwest of Washington, D.C. The National Naval Medical Center includes a hospital, medical and dental schools, and a school of hospital administration. It opened in 1942. The first nuclear reactor installed in a hospital solely for medical use was dedicated at the center in 1957.

**National Optical Astronomy Observatories (NOAO)** are a group of astronomy research centers funded by the United States government. The NOAO consists of three observatories. The observatories are Kitt Peak National Observatory near Tucson, Arizona; Cerro-Tololo Inter-American Observatory in northern Chile; and the National Solar Observatory in Arizona and New Mexico.

The NOAO was established in 1984 to combine the nation’s major centers for optical astronomy into a single organization. Optical astronomy involves the use of optical telescopes, which capture visible light and infrared (heat) radiation to form images of the sun, planets, stars, galaxies, and other celestial objects.

The NOAO provides major research facilities to astronomers. Any astronomer can apply for time on NOAO telescopes to carry out research. In addition, the NOAO maintains a staff of astronomers who improve and develop the observatories’ instruments, as well as conduct research.

Kitt Peak National Observatory is on Kitt Peak, about 60 miles (95 kilometers) southwest of Tucson. The observatory has 16 optical telescopes, the world’s largest collection. Its biggest telescope is the 4-meter Mayall telescope, which contains a mirror 158 inches (4 meters) in diameter. Between 300 and 400 astronomers from throughout the United States and other countries use Kitt Peak facilities each year.

Cerro Tololo Inter-American Observatory is on Cerro Tololo, a mountain about 50 miles (80 kilometers) east of La Serena, Chile. The observatory’s 158-inch (4-meter) telescope is one of the largest optical telescopes south of the equator. Astronomers at the observatory study celestial objects that cannot be seen from the Northern Hemisphere.

The National Solar Observatory, based in Tucson, conducts studies of the sun. It operates the Vacuum Tower telescope and other telescopes on Sacramento Peak, New Mexico, and the Robert R. McMath solar telescope and a vacuum telescope at Kitt Peak. Vacuum telescopes are enclosed in a vacuum chamber to eliminate the air turbulence produced inside other telescopes by the sun’s heat. The McMath telescope is the world’s largest solar telescope, with a mirror 60 inches (1.5 meters) in diameter. It produces an image of the sun about 30 inches (75 centimeters) in diameter.

The NOAO also conducts special programs in astronomy. One such program, called the Global Oscillation Network Group Project (GONG), uses a worldwide network of automated observatories to continuously study vibrations on the sun’s surface. The NOAO’s United States Gemini Program participates in an international partnership that operates two 319-inch (8.1-meter) telescopes. The Gemini North telescope is on Mauna Kea in Hawaii, and the Gemini South telescope is on Cerro Pachón, near Cerro Tololo in central Chile.

The NOAO is operated by the Association of Universities for Research in Astronomy, Incorporated (AURA), which consists of 21 U.S. universities. AURA is under contract to the National Science Foundation, a federal agency.

**National Organization for Women (NOW)** is one of the largest associations in the United States devoted to achieving full equality between women and men. NOW pushes for equality through elections and legislation as well as through rallies, demonstrations, and marches. The organization has hundreds of thousands of members in chapters throughout the nation. Almost all the members are women.

NOW seeks to increase the number of women in policymaking positions in government, businesses, schools, and other institutions. It works to replace male elected officials with women who support equality between the sexes. NOW also calls for giving women equal access to jobs, pensions, and Social Security benefits. It tries to ensure that women get the same pay as men for similar work.

The organization supports legalized abortion and access to birth control. It seeks to guarantee women a right to prenatal care (medical care during pregnancy) and child care. NOW also works to protect women against sexual assault and other violence. In addition, it seeks to enable both female and male homosexuals to live in security and with self-respect.

NOW calls for the passage of an Equal Rights Amendment to the Constitution of the United States. The amendment would require that men and women be treated equally by law. NOW’s first attempt to win approval of the amendment failed because only 35 of the necessary 38 states had approved it by a 1982 deadline. Since then, the amendment has been reintroduced in Congress a number of times but has not been passed.

Many people, including a large number of women, oppose NOW’s goals, its methods, or both. Some of these people object to the organization’s support for abortion. Many of NOW’s opponents believe that the welfare of society and of the family depends on preserving the traditional roles of men and women. These people criticize NOW for working to change women’s roles. Some people dislike NOW’s use of rallies, marches, and demonstrations to achieve its goals.

NOW disagrees that its activities weaken society or the family. The organization also points out that it supports the rights of all women, including homemakers, and that it acknowledges homemakers’ vital contributions to society and the family.

NOW was established in 1966. Betty Friedan, one of its founders, served as the organization’s first president. NOW headquarters are located in Washington, D.C.

Susan Lutz Wallace

A **national park** is an area set aside to protect natural beauty or other notable features. The magnificent scenery of Banff National Park in Canada includes snow-covered Mount Victoria and sparkling Lake Louise, above. Such beauty makes Banff one of the favorite parks in North America.

**National park**

**National park** is an area set aside by a nation's government to protect natural beauty, wildlife, or other remarkable features. National parks also preserve places of cultural, historical, or scientific interest. In addition, some parks protect entire environments, such as coral reefs, deserts, grasslands, mountain ranges, or rain forests. Governments create national parks to guard their natural treasures from the harmful effects of farming, hunting, logging, mining, and other economic development.

National parks serve important purposes. Many parks allow us to enjoy and appreciate majestic peaks, sparkling lakes, spectacular waterfalls, and other scenic wonders. Others let us see fascinating wild animals in their natural settings. Still others provide opportunities for boating, camping, hiking, and other forms of recreation. As a means of attracting tourism, national parks are vital to the economies of many nations.

In addition, many national parks foster education by preserving important buildings, battlegrounds, and other features of a nation's cultural and historical heritage. Parks help save endangered animals and plants, and they provide natural laboratories for scientists seeking to understand relationships of animals and plants to their environment. Another goal of many parks is to protect the area's **biodiversity** (variety of plant and animal species). In this way, parks help maintain a healthy balance among species and help preserve the natural processes that support life on the earth.

National parks face a number of challenges. Many park managers must deal with pressures to develop park resources. They also are concerned about poaching (illegal hunting), the collection of rare plants, pollution, and overcrowding. Other concerns include the rights of the people who were the parks' original inhabitants, and the wise management of natural forces such as fire and wildlife.

The world's first national park, Yellowstone National Park, was established in the United States in 1872. National parks gradually spread throughout the world. Today, about 1,500 national parks protect about 1.4 million square miles (3.9 million square kilometers) in more than 120 countries. Many countries use the term **nature reserves** for areas similar to national parks. There are about 6,000 of these areas. Together, the world's national parks and nature reserves cover an area about the size of the mainland United States.

**Notable national park systems**

A number of countries have developed important national park systems. These countries include Argentina, Australia, Canada, Japan, Kenya, New Zealand, South Africa, and the United States.

---

Craig W. Allin, the contributor of this article, is Professor of Political Science at Cornell College and the editor of International Handbook of National Parks and Nature Reserves.
Argentina has about 20 national parks. The parks cover a total of about 10,000 square miles (26,000 square kilometers). The country’s first national park, the National Park of the South, was established in 1922 to preserve an area of scenic mountains.

Argentina’s national parks protect a huge range of geographical features, plants, and animals. The most notable parks include Nahuel Huapi, Los Glaciares, and Iguazu. Nahuel Huapi was originally called National Park of the South. It took its present name in 1934. It is Argentina’s largest national park, covering about 3,000 square miles (7,800 square kilometers). Only slightly smaller is Los Glaciares, which has nine major glaciers. Together, Iguazu National Park in Argentina and Iguazu National Park in Brazil protect the magnificent Iguazu Falls and about 900 square miles (2,300 square kilometers) of tropical rain forest. The waterfall actually consists of about 275 separate falls. The combined falls measure about 2 miles (3 kilometers) wide and drop 237 feet (72 meters).

Australia has about 500 national parks. The first one, established in 1879, was National Park (now called Royal National Park). Today, the system extends over 100,000 square miles (275,000 square kilometers).

Australia’s history makes its parks especially important to scientists. About 200 million years ago, Australia broke apart from a huge land mass that is now Africa and South America. As a result, Australia’s wildlife developed differently from the wildlife on the other continents. Kangaroos, koalas, wombats, and thousands of other animals and many plants are unique to Australia.

Australia’s Great Barrier Reef Marine Park and Kakadu National Park are of exceptional interest. Great Barrier Reef, a large group of coral reefs in the South Pacific Ocean, is the largest marine reserve in the world. It extends about 1,400 miles (2,300 kilometers) along Australia’s northeast coast. The park is home to about 400 species of coral, 200 kinds of birds, and thousands of different species of fish and shellfish.

Kakadu National Park protects evidence of human life from about 30,000 years ago. This evidence includes one of the world’s greatest collections of prehistoric cave paintings. Kakadu is a pioneer in cooperative management. Most of the park belongs to groups of Aborigines, whose members are descendants of hunting and gathering people who were Australia’s earliest inhabitants. The Aborigines have leased their lands to the federal government with the understanding that the park will be managed to preserve their traditional ways of life.

The spectacular Iguazu Falls lies on the border between Brazil and Argentina and forms a part of national parks in each country. The waterfall actually consists of about 275 separate falls. The combined falls measure about 2 miles (3 kilometers) wide and drop 237 feet (72 meters).
The Great Barrier Reef Marine Park stretches about 1,400 miles (2,300 kilometers) along Australia's coast. Its approximately 400 species of colorful coral attract many divers.

Canada has about 35 national parks that occupy a total of about 85,000 square miles (220,000 square kilometers). The Canadian system of national parks began in 1885, with land near Banff, Alberta. This area became part of what is now Banff National Park.

Canada has pioneered an ecosystem approach to park planning. An ecosystem consists of all the living and nonliving things in a given area and the relationships among them. An area's air, climate, soil, and water are part of its ecosystem. Under the ecosystem approach, Canada's park service has divided the country into about 70 areas, each with a different combination of land, water, plants, and animals. National parks are developed around the relationships among the natural features in each area.

The Canadian park system is exceptionally diverse. Banff, Jasper, Kootenay, and Yoho national parks protect almost 8,000 square miles (20,700 square kilometers) of mountain ecosystem. These four adjacent Rocky Mountain parks have rugged peaks, active glaciers, glistening lakes, thundering waterfalls, and boiling hot springs. The parks are home to grizzly and black bears, bighorn sheep, deer, elk, moose, mountain goats, and dense forests of evergreen trees.

In addition, Canada has begun to develop a system of marine parks to protect underwater environments in the Atlantic, Pacific, and Arctic oceans and in the Great Lakes. Its first national marine park, Fathom Five, was established in 1987 in Lake Huron's Georgian Bay. The bay's cold, clear waters preserve several historic shipwrecks and provide opportunities for recreational divers. For a complete listing of Canada's national parks and historic sites, see Canada (National park system).

Japan has about 80 national parks. The parks cover about 13,000 square miles (34,000 square kilometers). The national parks of Japan are rooted in both religion and recreation. Japan's major religions, Buddhism and Shintoism, stress harmony with nature and deep respect for living things. The Japanese people regard forests, islands, mountains, and other places of special beauty as sacred. For centuries, they treated such places as shrines and left them unspoiled. To protect the beauty of Japan's scenic mountains, the government created the country's first national park in 1934. In the mid-1900's, the growing popularity of mountain climbing led to the expansion of Japan's national park system.

Japan's park planners have been challenged by the country's huge population and small area. Japan is one of the most densely populated nations in the world. As a result, little unused land is available for the creation of national parks. Japan's solution has been to establish national parks that include private lands. The government then works with the landowners to save the natural beauty of each area. About a fourth of Japan's parkland is privately owned.

Japan's best-known scenic treasure is Mount Fuji, a beautifully shaped volcano in Fuji-Hakone-Izu National Park. This park lies near Tokyo and other large cities and attracts about 100 million visitors each year.

Kenya has about 30 national parks and reserves. Its national park system covers about 14,000 square miles (36,000 square kilometers) and protects a spectacular variety of wild animals. The national parks of Kenya date to the early 1900's, when colonial governments set aside wildlife reserves mainly to provide sightseeing and hunting opportunities for Europeans. Today, the money spent by tourists visiting the national parks is a major source of Kenya's national income.

Kenya's most famous protected areas include Tsavo National Park and Maasai Mara Game Reserve. Both lie in the grasslands of East Africa. Tsavo is Kenya's largest park. It covers about 8,000 square miles (20,700 square kilometers) and is known for its elephants and rhinocer-
os. Maasai Mara lies next to the Serengeti National Park in Tanzania. It is home to antelopes, buffaloes, cheetahs, elephants, giraffes, hippopotamuses, hyenas, jackals, leopards, lions, rhinoceroses, and many kinds of birds. Between August and October, hundreds of thousands of migrating zebras and wildebeests from the Serengeti Plain cross into Maasai Mara.

**New Zealand** has about 15 national parks. These parks cover about 9,000 square miles (23,000 square kilometers). New Zealand’s national park system grew from the beliefs and vision of its original inhabitants, the Maori. The Maori feared that Europeans settling in the country in the late 1800s would not respect their sacred volcanoes. In 1887, a Maori chief gave land to the government for a park. The area was expanded and became Tongariro National Park in 1894.

Saving nature has special importance in New Zealand, an island country. New Zealand separated from the other continents about 80 million years ago. When Europeans began arriving in the 1800s, more than half of New Zealand’s native plants and animals were unique to the island. But European settlers introduced many new plants and animals to New Zealand. The results have been disastrous for the native species. In many parts of the country, most native plants and animals have been destroyed.

Fiordland, New Zealand’s largest national park, has about 15 **fjords** (narrow inlets from the sea) that extend up to 27 miles (43 kilometers) long and about 1,600 feet (500 meters) deep. This park also includes evergreen forests and Sutherland Falls, which drops 1,904 feet (580 meters) and ranks as one of the world’s highest waterfalls. The national parks have helped make tourism and outdoor recreation major industries in New Zealand.

**South Africa** has about 15 national parks. The parks occupy about 12,000 square miles (31,000 square kilometers). The country’s first national park, Kruger National Park, was established in 1926. Nature observers have called South Africa’s animal population "the greatest wildlife show on earth." Not surprisingly, the history of South Africa’s national park system has focused on wildlife protection. Kruger National Park and Kalahari Gemsbok National Park stand out for their enormous size and great variety of wildlife.

Kruger covers about 7,500 square miles (19,500 square kilometers) and may have the largest variety of mammals in any African park or reserve. It has thousands of buffaloes, elephants, impalas, and zebras, as well as hundreds of species of birds and plants. The park’s grasslands are home to antelopes, cheetahs, giraffes, hyenas, jackals, leopards, and lions. Crocodiles and hippopotamuses live in the rivers. Kruger has become a world center for wildlife research.

Kalahari Gemsbok National Park was established in 1931 to protect herds of migrating animals. It covers about 3,700 square miles (9,600 square kilometers) and lies next to Gemsbok National Park in Botswana. These parks are famous for their various species of antelopes, including elands, gemsboks, springboks, steenboks, and wildebeasts, as well as for cheetahs, hyenas, jackals, and lions.

The **United States** has about 50 national parks. These parks and over 300 other protected areas in the country’s National Park System occupy about 125,000 square miles (325,000 square kilometers). The U.S. government’s work in establishing and managing national parks has

---

The sprawling Kruger National Park in South Africa is home to thousands of mammals, including impalas and waterbucks, *shown here*. The park covers about 7,500 square miles (19,500 square kilometers) and ranks as one of the leading centers of wildlife research in the world.
served as a model for countries around the world. The opening of Yellowstone National Park in 1872 was soon followed by the creation of many other important national parks. To preserve recreational opportunities in natural settings, the government set aside more than 400 wilderness areas, mostly within national parks, national forests, and national wildlife refuges. For more information on U.S. parks, see National Park System.

Other interesting national parks

More than 120 countries have established national parks. A number of these parks are famous throughout the world and attract millions of visitors annually. Tourists are often drawn by the variety of wildlife in a country's national parks. Costa Rica's parks are especially popular because they have more species of birds—about 850—than do the United States and Canada combined. This small country's national parks also protect about 9,000 species of plants.

Many people are attracted by the outstanding features of individual parks as well. Some of these parks are considered world treasures. For example, Nepal's Sagarmatha National Park includes "the peak whose head touches the sky," according to local peoples. Westerners know this majestic, snow-capped peak as Mount Everest, which rises to 29,035 feet (8,850 meters) and is the highest peak in the world. Guatemala's Tikal National Park protects pyramids of the ancient Maya civilization.

Another famous protected area, Ecuador's Galapagos National Park, preserves the natural laboratory that influenced the British biologist Charles Darwin. Darwin's studies there contributed to his famous theory of evolution. England's Lake District inspired the British poet

(Continued on page 42h)
### Interesting national parks throughout the world

By 2000, there were about 1,500 national parks in the world. These parks protected about 1.7 million square miles (3.9 million square kilometers) in over 120 countries. Examples of interesting national parks throughout the world are described below and on page 42g.

Wildlife preservation is a key goal of national parks throughout the world. Indonesia’s Komodo National Park protects the endangered Komodo dragon, above left, and China’s Wolong Natural Reserve shelters the rare giant panda, above right.
William Wordsworth long before it became a national park in the 1950's. Victoria Falls National Park in Zimbabwe and Mosi oa Tunya National Park in Zambia share protection of Africa's most famous waterfall. This landmark, the magnificent Victoria Falls, drops 355 feet (108 meters).

Many of the world's national parks are vital to wildlife preservation. Wolong Natural Reserve in China shelters rare giant pandas. Indonesia's Komodo National Park provides a habitat for the endangered Komodo dragon, a lizard that may grow over 10 feet (3 meters) long and weigh up to 300 pounds (135 kilograms). India's national parks, such as Ranthambhore, have probably saved the Indian tiger from extinction. The marshlands of Doñana National Park in Spain provide food and shelter to nearly half the bird species in Europe.

**Challenges for the parks**

People often think of the world's national parks as islands of unspoiled nature. We assume these parks are safely separated from a world rapidly becoming more urban, more industrial, and more artificial. The world's national parks, however, are part of the world in which we all live. What we do affects the parks and may threaten their existence.

Today, national parks face several major challenges. Major threats come from pressures to develop park resources, from environmental change, and from overcrowding. Park managers also struggle to guarantee the rights of the land's original inhabitants and to ensure sound management of fire and wildlife.

**Development of park resources.** Many national parks were set aside in the belief that they had little or no commercial value. Later, however, people discovered that many of the parks contain valuable resources. There are trees that might be cut, minerals that might be mined, grass that might be grazed, and land that might be farmed. There are also animals that might be captured or killed for sport or financial gain. The resources inside the parks will become increasingly valuable as resources outside the parks are exhausted. The commercial development of park resources often will produce more jobs and economic growth in the short term than will preservation of the parks.

Pressures to develop park resources generally cause only minor problems for governments of rich nations, where economic growth is strong. These governments have more ways to protect their national parks than developing nations. People of wealthy nations also do not need to use park resources for survival.

In developing nations, however, the situation is different. In such countries, especially in Africa and South America, governments may be forced to sacrifice parks in favor of economic development. Large corporations may acquire the right to use park resources by paying public officials for their cooperation. Many landless peasants seek park resources for survival. They may view the parks as the only lands available for collecting firewood, for building homes, for hunting food, or for raising crops.

Poachers also invade many parks. Many of these illegal hunters seek profits by killing animals for valuable body parts. For example, poachers slaughter leopards for their skin, elks for their antlers, elephants for their tusks, and rhinoceroses for their horns. Poachers also collect live animals for illegal sale, especially small birds that can be sold as pets. Some people also take rare plants from the parks. Where all or most of these pressures on park resources are severe, the parks may not survive.

**Changes in the environment** also endanger the parks. Various forms of pollution—especially air and water pollution—present major threats because they easily cross park boundaries. For example, the scenic views of Grand Canyon National Park in the United States are often reduced due to air pollution from Los Angeles, which lies about 300 miles (480 kilometers) away. In addition, the park's environment has suffered from the construction of dams upstream on the Colorado River, which flows through the Grand Canyon. Changes in the flow of water have harmed water birds and other wildlife in the park.

Worldwide environmental problems also threaten national parks. These problems include an increase in the so-called greenhouse effect and the rapid reduction of tropical rain forests. The greenhouse effect is a warming at the earth's surface that results when the earth's atmosphere traps the sun's heat. The heat is trapped when it is absorbed by carbon dioxide and other gases in the atmosphere.

The amount of carbon dioxide in the atmosphere has grown because of the increased burning of such fuels as coal, gas, and oil. Rain forests absorb large amounts of carbon dioxide. But the forests can handle less and less carbon dioxide because developers and farmers...
Some scientists are concerned about the effect of higher temperatures on the earth's surface. They warn that global warming may produce mass extinction of plants and animals and other harmful effects.

Overcrowding. The world's national parks have experienced dramatic growth in tourism during the 1900's. However, some popular parks are actually endangered by their admiring visitors, especially in the United States, Japan, and other wealthy nations with large populations. Too many visitors can harm the natural environments that national parks are set aside to protect. In some popular national parks, for example, visitors' automobiles create traffic jams, kill wildlife, and pollute the air. In addition, overcrowded campgrounds increase the level of litter and destroy the unspoiled beauty of scenic areas.

Overcrowding creates a difficult choice for park managers. Tourist spending demonstrates that park preservation has economic as well as spiritual value. In fact, income from tourists visiting the national parks in Africa is vital to the economies of many nations there. Nevertheless, managers have had to limit the number of cars and campers, and to establish other restrictions to protect park resources for future generations.

The rights of original inhabitants. The peoples who live in and near national parks are especially concerned about who benefits from tourism in the parks. In some countries, the benefits have gone to political officials who control the parks and to large foreign-based corporations. The original inhabitants may then see the parks as a foreign idea and one damaging to their lives. As a result, they may oppose the establishment and preservation of national parks.

Some park managers concerned for the rights of local peoples look to New Zealand and Australia for solutions. In those countries, the Maoris and the Aborigines support the creation of national parks as a way to preserve their sacred places and traditional ways of life. The cooperation of the Aboriginal groups and the Australian National Park and Wildlife Service at Kakadu National Park, for example, may serve as a model for other countries.

Management of fire and wildlife. Fire and wildlife often cause problems for park managers. Both fire and wild animals must be handled naturally to preserve a park's ecosystem. If allowed to burn freely, fire destroys old and diseased trees and shrubs and helps nourish the soil. These conditions promote new growth. Allowing animals to hunt and roam freely helps parks maintain a balanced and varied wildlife community.

However, fire and wild animals may threaten neighboring crops, livestock, property, and people. Neither fire nor animals recognize park boundaries. As a result, park managers must find ways to prevent fire and wildlife from passing over park boundaries. Solving this problem is difficult because some solutions can lead to other problems. For example, park officials can use modern techniques to extinguish fires, and they can build fences to prevent animals from roaming outside the parks. But such actions can upset the delicate balance required for healthy wildlife populations and damage the ecosystem.

Park managers also must maintain an adequate amount of vegetation in the parks for plant-eating animals. Overgrazing can lead to starvation for such animals. This problem may result if a park lacks animals that prey on the plant-eating animals. Overgrazing has developed in Yellowstone National Park in the United States, partly because of an elk population unchallenged by predators.

The Grand Canyon of the Yellowstone cuts across Yellowstone National Park in the United States for about 20 miles (32 kilometers). The Yellowstone River flows through the canyon, creating two waterfalls. Yellowstone, the world's first national park, was established in 1872.
by natural predators. Park managers have added wolves, a natural enemy of elk, to the park's wildlife.

History

Throughout history, people have preserved and protected places they considered special. But it was not until the 1800's that governments became active in establishing national parks.

The early national parks. The United States pioneered the development of national parks. Americans became interested in protecting the nation's wilderness as the country expanded westward during the 1800's. In 1832, the artist George Catlin became one of the first noted Americans to publicly call for the creation of a national park. In 1858, the writer Henry David Thoreau also promoted the idea. Both Catlin and Thoreau also saw national parks as places where American Indians could preserve their vanishing cultures. The dream of a great national park became a reality in 1872, when President Ulysses S. Grant signed a law creating Yellowstone National Park.

The national park idea spread to other countries. In 1885, the Canadian government established a park around the hot springs at Banff, Alberta. During the next 40 years, national parks opened in Australia, Germany, Italy, New Zealand, South Africa, Spain, Sweden, and Switzerland. Also during this period, Belgium and France established national parks in their colonial possessions in Africa.

International concern for national parks. The growth of national parks around the world led to the formation of international conservation organizations. In 1948, the International Union for the Protection of Nature was founded. In 1956, it was renamed the International Union for the Conservation of Nature and Natural Resources and became known as the IUCN. In 1960, the IUCN established the International Commission on National Parks. The commission became the Commission on National Parks and Protected Areas in 1975. This commission has taken the lead in organizing world conferences on national parks.

The United Nations Educational, Scientific and Cultural Organization (UNESCO) established two other important conservation programs. It founded the Man and the Biosphere Program in 1971 to preserve ecosystems throughout the world for scientific and educational purposes. In 1978, UNESCO released the first World Heritage List, which recognized areas of unique natural or cultural importance.

The national park movement today. By the 1990's, the idea of establishing national parks had proved popular and had spread to most of the world's countries. Planners put more emphasis on creating parks to preserve the full range of a nation's plants, animals, and landscapes. They stressed the value of establishing parks in areas of scientific and environmental importance even if those parks might not be particularly popular with tourists.

People also increasingly recognized that national parks are not natural islands that can be maintained separately from the world around them. Now we know that the survival of national parks depends on what we do both inside and outside the parks. Craig W. Allin

Questions

What are some purposes of national parks?
Why does Australia's history make its parks especially important to scientists?
What is Canada's ecosystem approach to park planning?
Why are Japan's national parks rooted in both religion and recreation?
What is the Man and the Biosphere Program? The World Heritage List?
Which park was the world's first national park?
What problems does overcrowding cause in some popular parks?
Why may the peoples who live in or near national parks oppose the establishment of parks?
What have people increasingly recognized about national parks?
What worldwide environmental problems threaten national parks?

Additional resources

National Park Service is a bureau of the United States Department of the Interior. It manages the more than 380 areas of the National Park System. The bureau preserves many natural landscapes and historic and archaeological sites and structures. The bureau was established in 1916, when the U.S. park system consisted of 37 areas. These areas included Yellowstone National Park, the world's first national park. The U.S. secretary of the interior appoints a director to head the bureau in its Washington, D.C., headquarters. The bureau has 10 regional offices, a planning and service center, and two training centers. Critically reviewed by the National Park Service

See also National Cemetery; National Park System.
National Park System

The president of the United States appoints a director to head the National Park Service. The director names a superintendent to manage an individual area or a group of areas close together. Park rangers work to protect the parklands from damage and provide various services for visitors (see National Park Service). See also the articles on the various parklands listed in the tables with this article. For information on national parks throughout the world, see the World Book article National park.

Kinds of parklands

There are about 20 different types of areas in the National Park System, including national parks, national monuments, national memorials, and national historic sites. See the table of Types of areas.

The different types of areas in the National Park System are preserved for three basic reasons. Areas may have (1) beautiful or unusual natural features, (2) historical importance, or (3) attractive recreational features. Many areas are set aside for more than one reason.

Areas preserved for natural features. Most national parks are preserved chiefly for the outstanding beauty or scientific importance of their natural features. For example, Yellowstone National Park, which covers parts of Idaho, Montana, and Wyoming, is world famous for its natural wonders. They include hot geysers that erupt from the ground, thundering waterfalls that plunge into deep gorges, and sparkling lakes that lie high among snow-capped mountains. Death Valley National Park, partly in Nevada and partly in California, is preserved for...
Parklands of the National Park System

These maps show the locations of the parklands in the National Park System. Because of space limitations on the large map, the parklands within the metropolitan areas of Boston, New York City, Philadelphia, and Washington, D.C., are listed on the right side of this map.
its strange and beautiful rock formations. It has the lowest land surface in the Western Hemisphere—282 feet (86 meters) below sea level.

Many national monuments are preserved for unusual features. Among these are Agate Fossil Beds National Monument in Nebraska, which has deposits of ancient animal fossils, and Craters of the Moon National Monument in Idaho, which features lava fields with volcanic caves, cinder cones, craters, and tunnels.

**Areas preserved for historical importance** include ancient ruins, such as the remains at Georgia's Ocmulgee National Monument of Indian mounds and towns, some dating from 8000 B.C. Others honor important people or events in the history of the United States. These areas include battlefields, forts, and other military sites, and historic bridges, buildings, dams, canals, and farms. The homes of many U.S. presidents and other noted Americans are among the national historic sites. The most famous historical area is probably the White House, in Washington, D.C.

The historical areas look much as they did when they became important. Staff members sometimes restore buildings and natural features, raise animals on the farms, and wear clothing styles from the past.

**Areas preserved for recreational use.** National recreation areas, national seashores, and national lake-shores provide land and water resources for outdoor activities. For example, 68 miles (109 kilometers) of white sand beaches and dunes line the Gulf of Mexico at Padre Island National Seashore in Texas. The area's fishing, horseback riding, sailing, and swimming attract visitors from all parts of the country.

In other areas of the National Park System, such features as roads, trails, and water reservoirs have been developed to provide recreational opportunities. For example, one of the world's largest artificially created lakes, 250-square-mile (650-square-kilometer) Lake Mead, is a popular playground for water sports. Formed by Hoover Dam, the lake is part of the Lake Mead National Recreation Area, which lies partly in Arizona and partly in Nevada.

The park system also has cultural areas that provide attractive settings for fine arts performances. One such area is the Wolf Trap Farm Park for the Performing Arts in northeastern Virginia, which presents concerts and other fine arts programs in its auditorium. Lawns around the auditorium provide seating space for thousands of additional people.

**Visiting the parklands**

Hundreds of millions of people visit the parklands in the National Park System each year. Many parklands offer free admission. Some areas allow camping or have lodgings for overnight stays.

**Planning a visit.** Learning about a parkland beforehand will increase the enjoyment of a visit. It is helpful to know what natural or historical features to look for and why they are important. For an overnight stay, visitors should find out whether the area has lodgings or campgrounds that will be open. It is also useful to know about available services and recreational activities, traveling routes, and various fees.

The tables with this article show which parklands have overnight lodgings, permit camping, are closed part of the year, or are not yet open to the public. The National Park Service provides additional information through its Web site at www.nps.gov to help plan a park visit. Area superintendents will mail other information upon request. For their addresses, write to Public Inquiries, National Park Service, 1849 C Street NW, Washington, DC 20240.

Visitors should stop at a parkland's visitor center for pamphlets and maps that tell about the area's features and activities. At many parklands, staff members offer campfire talks, guided trips, and amphitheater programs.

**Visitors' costs.** About two-thirds of the parklands are free to the public. The others charge a daily entrance fee. People under the age of 16 and organized groups of high school age pay no entrance fee.

The Park Service sells Golden Eagle Passports, which may be used for a year at all parklands that charge an entrance fee. People 62 or older may obtain a free Golden Age Passport. People who are blind, have permanent disabilities, or qualify for disability benefits may obtain a free Golden Access Passport. These two passports offer the same privileges as the Golden Eagle Passport as well as a 50 percent discount on other fees.

Overnight lodgings vary in price, according to quality. They include cabins, cottages, lodges, motels, hotels, and trailer villages. These lodgings, available in dozens of areas, are operated privately under contract with the National Park Service. Visitors should make reservations early. The busiest periods, except in warm climates, are

*Listed in the order that they appear in the following tables in this article.
from late May to mid-October, and weekends and holidays the rest of the year.

Camping is permitted in about 100 national parkslands—in the wilderness or on campgrounds. A wilderness site may be a great distance from such conveniences as drinking water and food supplies. Wilderness campers must notify the superintendent or a park ranger of their plans. Back-country camping opportunities are available in more than 100 parks.

Inexperienced campers should camp on campgrounds. Some of these sites have few conveniences, and others have many, including play areas for children. Some campgrounds are designed for individuals or for families or other small groups. Other sites are intended for large, organized groups, such as school groups. Reservations can be made for group sites. Commercial reservation service is available for a few popular campgrounds. For camping tips, see the Camping article.

Visitors' responsibilities. Visitors share with park rangers the responsibility of protecting the parklands. Carelessness can start a forest fire that could destroy lives and valuable resources. Visitors are not allowed to remove or damage any natural feature—not even a flower. The National Park Service repeatedly warns the public not to feed, tease, or touch any animals of the parklands.

Preserving the parklands

Limits on activities. To keep the parklands in an unspoiled condition, the National Park Service strives to disturb the plant and animal life as little as possible. The Park Service allows fishing, but hunting, lumbering, and mining are prohibited in most areas. Livestock grazing is limited and is steadily being eliminated. In most areas, water resources may not be used for such purposes as irrigation or the production of hydroelectric power.

The National Park Service encourages recreational activities in the parklands if they do not disturb the surroundings. The service tries to teach people about the natural processes that have made the land of each area what it is. Park rangers and other staff members are trained to explain natural and scientific features to visitors. The service also encourages research and educational activities in all of the nation's parklands.

Fires are an essential process in many natural areas, including forests and prairies. For this reason, the Park Service permits fires started by lightning to burn in certain parks, as long as the flames do not threaten human lives, buildings, or rare resources. But the Park Service fights any fire started by people, such as careless campers or smokers.

Crowds. The ever-increasing number of visitors puts pressure on the national parkslands. Problems include demands for such basic services as food, water, lodging, and transportation. Only through careful planning and management can these problems be handled without spoiling the parklands. Otherwise, overcrowding could result in too much automobile traffic, air pollution from automobile fumes and campfire smoke, dirty streams, and jammed campgrounds.

The National Park Service has taken many steps to correct early mistakes in parkland development. It has tightened controls on air and water pollution, food supplies, and health care. In Yosemite National Park, for example, public transportation was begun to reduce automobile traffic. The Park Service also cut the number of campers permitted in overcrowded Yosemite Valley.

Establishing new parklands

National parks can be created only through acts of the U.S. Congress. Congress must also approve nearly all other new areas for the National Park System. The president may establish a national monument if the government owns the land. The secretary of the interior may approve a national historic site.

Congressional committees usually hold hearings about adding particular lands to the park system. The secretary of the interior makes recommendations based on a study of an area's significance conducted by Park Service personnel.

The National Park Service acquires new land through donations, exchanges, purchases, or reassignment of federal properties. Many parklands in the system include some land that the government does not own. The government is gradually acquiring these sections. Dozens of areas are owned by state, local, or private agencies. The National Park Service may contribute funds or provide technical advice and assistance to the agencies that manage these areas.

Continued on page 58

Redwood National Park is a redwood forest with some of the world's tallest trees. Visitors enjoy hiking in the forest.

## Outstanding features

- **Voyageurs**
  - Minnesota
  - Beautiful northern forests of aspen, birch, pine, and spruce; more than 50 lakes

- **Wind Cave**
  - South Dakota
  - Limestone caverns; prairie wildlife

- **Wrangell-St. Elias**
  - Alaska
  - Country's largest collection of glaciers and of peaks over 16,000 feet (4,877 meters)

- **Yellowstone**
  - Idaho, Montana, Wyoming
  - World's greatest geyser area; canyons and waterfalls; wide variety of wildlife

- **Yosemite**
  - California
  - Mountain scenery with deep gorges and high waterfalls

- **Zion**
  - Utah
  - Colorful canyons and mesas

Saint-Gaudens National Historic Site, in Cornish, New Hampshire, was once the home of the famous American sculptor Augustus Saint-Gaudens. The site includes his studio, shown here.

Oklahoma City National Memorial has chairs that represent the 168 people killed on April 19, 1995, when a terrorist bomb destroyed the Murrah Federal Building that stood on this site.

History

During the 1800’s, hunters and trappers returned from the Yellowstone region with reports of strange natural wonders. These stories—of hot springs, spouting geysers, and a mountain of black glass—seemed unbelievable. In 1870, an expedition led by General Henry D. Washburn, surveyor general of the Montana Territory, visited the region to check the reports.

After exploring by horseback, the men camped near the Madison River. They talked about the sights they had seen and discussed developing the land for resorts, or for lumbering and mining. Then, Cornelius Hedges, a Montana judge, proposed that the region be preserved as a national park to benefit all people for all time. Then, other men agreed enthusiastically.

Members of the expedition promoted the national park idea by writing articles in newspapers and magazines, giving lectures, and meeting with high government officials. Their efforts succeeded in 1872, when Congress established Yellowstone National Park, the world’s first national park. During the 1890’s, four more national parks were established—General Grant (now Kings Canyon), Sequoia, and Yosemite in California, and Mount Rainier in Washington.

In 1906, Congress passed the Antiquities Act to stop looting and destruction at prehistoric Indian sites in the Southwest. This law gave the president the power to establish national monuments on land owned or controlled by the government. Later in 1906, Devils Tower National Monument in Wyoming became the first such area. More than 30 national monuments were established during the next 10 years.

In 1916, Congress set up the National Park Service as a bureau of the Department of the Interior. Stephen T. Mather, a Chicago businessman, became its first director. Mather did much to promote and expand the National Park System. In 1916, there were 16 national parks and 21 national monuments, with a total area of nearly 5 million acres (2 million hectares). When Mather retired in 1929, the system consisted of 25 national parks, 32 national monuments, and a national memorial. It had a total area of about 10 million acres (4 million hectares).

In 1933, Congress transferred more than 50 areas from other government agencies to the Department of the Interior. These areas, most of them historical, were added to the National Park System. In 1935, the Historic Sites Act gave the secretary of the interior the power to approve national historic sites.

The Park, Parkway, and Recreation Area Study Act of
1936 led to establishment of recreational areas in the National Park System. The first such area, the Blue Ridge Parkway, was established later that year. An act of 1946 allowed the Park Service to manage recreational areas under cooperative agreements with other government agencies that controlled the areas.

In the last half of the 1900's, much land was added to the National Park System. By the early 2000's, the system had grown to include over 380 areas and totaled more than 84 million acres (34 million hectares).

Critically reviewed by the National Park Service.

   B. Fires

IV. Establishing new parklands

V. History

Questions

Where is the largest national park in the United States? What efforts are made to preserve the plant and animal life in the parklands? What was the first national monument? Who was the first director of the National Park Service? What is a Golden Eagle Passport? How does the National Park Service acquire land? What area became the first national park in the world in 1872? What are the three basic reasons for including land in the National Park System? What government agency must establish a new national park? What national park has the smallest land surface in the Western Hemisphere?

Additional resources

National Primitive Baptist Convention in the U.S.A. is a religious organization that has more than 2,000 churches. Each church is independent in controlling its own membership. These Baptists follow three ordinances (established religious ceremonies) — baptism, Holy Communion, and foot washing rites. They believe that a definite number of the human race were chosen for redemption before the world was created, and these persons will be saved before the final judgment. The convention was formed in 1907. It consists of state conventions and associations. It operates a publishing house, women’s auxiliaries, training unions, and church schools. The organization’s headquarters are in Tallahassee, Florida. See also Baptists.

Critically reviewed by the National Primitive Baptist Convention in the U.S.A.

National PTA. See National Congress of Parents and Teachers.

National Public Radio (NPR) is a public radio system in the United States. It acquires or produces news, cultural, and information programming and distributes it to more than 600 member stations in the United States, Puerto Rico, and Guam.

Member radio stations produce many of the cultural programs presented nationally by NPR. The cultural programming includes live performances of classical and jazz music. Reporters from member stations regularly file stories heard on NPR’s newsmagazines.

The Corporation for Public Broadcasting, a private organization funded mainly by the federal government, created NPR to provide news programming and to link noncommercial radio stations across the United States. NPR was incorporated in 1970. Its first program transmission was live coverage of U.S. Senate hearings on the Vietnam War on April 19, 1971.

In 1977, NPR merged with the Association of Public Radio Stations and took on that organization’s former responsibilities. For example, it began providing member stations with training and program promotion, and representing the interests of public radio before Congress and the Federal Communications Commission. In 1979, it established the first nationwide, satellite-delivered radio distribution network. NPR’s headquarters are in Washington, D.C.

Critically reviewed by National Public Radio.

See also Corporation for Public Broadcasting.

National Radio Astronomy Observatory (NRAO) is an organization that operates radio telescopes at Socorro, New Mexico; Kitt Peak, Arizona; and Green Bank, West Virginia. Scientists from the United States and other countries use these telescopes. The NRAO is financed by the U.S. National Science Foundation and has scientific offices in Charlottesville, Virginia.

The NRAO operates the world’s most powerful radio telescope, the Very Large Array, near Socorro. This instrument consists of 27 large, dish-shaped metal mirrors called reflectors that collect radio signals from space. Each reflector measures 82 feet (25 meters) in diameter. The reflectors operate as a single instrument. Another NRAO instrument, the Very Long Baseline Array telescope, consists of 10 reflectors at sites across United States territory, from Hawaii to the Virgin Islands. They are controlled from Socorro by radio signals sent by a computer, and act as a single telescope.

The NRAO telescope at Kitt Peak has a 39-foot (12-meter) reflector designed to collect radio signals of extremely short wavelengths. At Green Bank, the NRAO operates the Robert C. Byrd Green Bank Telescope. The telescope’s reflector has an unusual shape. Its rim is a flattened circle with a shortest diameter of 328 feet (100 meters) and a longest diameter of 361 feet (110 meters). Also at Green Bank, the NRAO operates a radio telescope that is 140 feet (43 meters) in diameter.

The NRAO was founded in 1956 by the National Science Foundation, Associated Universities, Inc., an association of nine U.S. universities, operates it. Scientists using NRAO telescopes have detected radio waves given off by nearly all types of objects in space. These objects range from nearby planets to distant quasars.

Critically reviewed by the National Radio Astronomy Observatory.

National Railroad Passenger Corporation. See Amtrak.

National Recovery Administration (NRA) was a United States government agency in the early 1930’s. It was established in 1933 under the National Industrial
Recovery Act as part of the New Deal program (see New Deal). The NRA prepared and oversaw codes of fair competition for businesses and industries. Hugh S. Johnson was the first head of the NRA. President Franklin D. Roosevelt abolished the NRA in 1935, after the Supreme Court of the United States ruled the National Industrial Recovery Act unconstitutional. James T. Patterson

National Republican Party was a political party that arose when the Democratic-Republican Party split during President John Quincy Adams's administration (1825-1829). The National Republican Party supported Adams's administration, and the split pitted the party against the followers of Andrew Jackson. During Jackson's presidency (1829-1837), the National Republicans and other groups formed the Whig Party (see Whig Party).

William W. Freehling

National Research Council is a private, nonprofit organization in the United States that carries out much of the work of the National Academy of Sciences, the National Academy of Engineering, and the Institute of Medicine. The council aids the academies and the institute in furthering the development of science and technology and in advising the U.S. government and other organizations. Thousands of scientists, scholars, and researchers serve as volunteers on its study committees.

The National Research Council was created by the National Academy of Sciences in 1916. It undertakes most of its activities at the request of the U.S. government. The council also initiates its own studies and carries out research at the request of private foundations and other organizations. It is financed by government and private funds. Its headquarters are in Washington, D.C.

Critically reviewed by the National Research Council

See also National Academy of Sciences.

National Rifle Association of America is an organization that encourages sharpshooting and the use of firearms for hunting and other shooting sports. It opposes what it considers unnecessary restrictions on the right to own guns. Such restrictions include laws that impose cost or inconvenience on law-abiding gun owners. The association, also known as the NRA, supports laws that provide longer prison terms for people who commit crimes with firearms.

The NRA has based its opposition to gun control laws on the Second Amendment to the Constitution of the United States. This amendment reads: "A well-regulated militia, being necessary to the security of a free state, the right of the people to keep and bear arms shall not be infringed." However, in 1939, the Supreme Court of the United States ruled that the amendment does not prohibit most gun control laws.

Many people, including many law enforcement professionals, believe that stricter laws against owning and using guns would reduce the crime rate. The NRA feels that such laws would not help fight crime but would restrict the legal use of guns. The NRA has been effective at persuading Congress to block the passage of gun control bills. The NRA was founded in 1871. Its headquarters are in Fairfax, Virginia.

Franklin E. Zimring

See also Gun control; Second Amendment.

National Right to Life Committee is a leading organization in the movement against legalized abortion in the United States. Members try to influence Congress and the state legislatures to pass laws restricting access to abortion. The committee also attempts to defeat legislation that would extend abortion rights. In addition, the committee works to end infanticide (the killing of infants) and euthanasia (helping or allowing people to die).

The committee collects contributions from its members and gives the funds to political candidates it favors. The committee also conducts educational and outreach programs. These programs include National Teens for Life, a movement of young people opposed to abortion.

The committee was founded in 1973. That year, the Supreme Court of the United States made a landmark ruling in Roe v. Wade that states may not forbid abortions during the first three months of pregnancy. The committee has headquarters in Washington, D.C., and chapters in all 50 states. David M. O'Brien

National Road. In the early 1800s, many pioneers began moving into the territory west of the Ohio River. These settlers wanted their section to grow rapidly and began demanding a better route from the East to the West. In 1811, work began on a road that, when completed, led from Cumberland, Maryland, to Vandalia, Illinois. Over $7 million in federal funds was eventually spent on the road. It was known at first as the Great National Pike but later came to be called the National Road or the Cumberland Road. For many years, it was the chief road west. As railroads developed, the road became less important. See also United States, History of (picture: The National Road).

National Safety Council is a non-profit public service organization that works to increase safety and occupational health in the United States. The council has more than 35,000 members, including individuals, businesses, government agencies, schools, and civic, labor, and trade organizations. It promotes safe practices on and off the job and supports accident prevention laws and standards. The council produces films, pamphlets, and other materials on preventing accidents and illness.

The National Safety Council was founded in 1913 and chartered by the U.S. Congress in 1953. Its headquarters are in Chicago.

National Science Foundation is an independent agency of the United States government. It promotes science and engineering research in the United States by (1) providing fellowships (monetary awards) to individuals for research and graduate study; (2) funding research institutions; and (3) supporting national research facilities, including the National Center for Atmospheric Research in Colorado and various supercomputing centers. The National Science Foundation (NSF) also funds and coordinates U.S. research in the Arctic and Antarctica, and it supports international research programs.

In addition, the NSF seeks to improve education in mathematics, science, and engineering. It supports programs that enhance the skills of teachers and improve curricula (courses of study) at the elementary through high school levels.

Congress established the NSF in 1950. A director, deputy director, and a 24-member National Science Board head the foundation. They are appointed by the president, subject to Senate approval. The agency's
headquarters are in Arlington, Virginia.

Critically reviewed by the National Science Foundation

**National Security Agency/Central Security Service** is an agency of the United States Department of Defense. It has two primary missions: (1) ensuring the security of U.S. information systems and (2) gathering secret information transmitted by other countries. The agency is responsible for providing centralized coordination, direction, and performance of U.S. government activities related to these missions. The National Security Agency was established in 1952. The Central Security Service was created in 1972. Critical reviewed by the National Security Agency/Central Security Service

**National Security Council (NSC)** is a part of the Executive Office of the President of the United States. The council serves as an interdepartmental cabinet on defense, foreign policy, and intelligence matters. Members include the president, the vice president, and the secretaries of state and defense.

The NSC advises the president on many security problems. It brings together the departments and agencies most concerned with foreign policy and military matters. The council supervises the Central Intelligence Agency (see Central Intelligence Agency). The president calls meetings of the NSC. If a crisis develops, the president may call the group into immediate session.

The NSC is assisted by a staff headed by the assistant to the president for national security affairs. The staff works with the member departments and agencies to prepare studies and policy papers for the council's actions. Congress created the council in 1947.

In 1986, the NSC was criticized for exceeding its authority as an advisory agency. This criticism arose when it was revealed that the NSC staff carried out secret arms sales to Iran and provided the profits to U.S.-supported rebels in Nicaragua. Some legal experts argued that both activities violated federal government policies at the time. In 1987, President Ronald Reagan responded to the criticism by adding a special legal adviser to the staff of the NSC.

Harvey Glickman

**National Trails System** is a network of pathways and historic routes throughout the United States preserved for public enjoyment and in commemoration of significant periods or events in U.S. history. The system includes national scenic trails, national historic trails, national recreation trails, and connecting or side trails that provide access to these paths. The trails wind through rural, wilderness, and even urban areas. Three federal agencies—the National Park Service, the Forest Service, and the Bureau of Land Management—administer and coordinate the system.

National scenic trails provide opportunities for the enjoyment of outdoor activities and of spectacular natural beauty. The Appalachian National Scenic Trail, for example, extends more than 2,140 miles (3,444 kilometers) from Maine to Georgia. The trail, open only to hikers, hugs the crests of the Appalachian Mountains.

National historic trails mark significant periods or events in U.S. history. For example, the Oregon National Historic Trail preserves the 2,000-mile (3,200-kilometer) trail that was the pioneers' chief route to the Northwest during the westward expansion of the 1840's and 1850's.

National recreation trails are shorter trails that can be used for a wide variety of outdoor recreational activities, including bicycling, cross-country skiing, hiking, horseback riding, and snowmobiling.

The U.S. Congress established the National Trails System in 1968. The system originally included scenic trails, recreation trails, and connecting or side trails. Congress added the category of national historic trails in 1978.

**National Urban Coalition.** See Urban Coalition, National.

**National Weather Service.** See Weather Service, National.

**National Wildlife Federation** is an organization founded to create interest and promote public education in the conservation of wildlife and wildlife habitats in the United States. The federation issues several free or inexpensive publications. It also publishes several magazines, including *National Wildlife* and *International Wildlife* for its adult members; *Ranger Rick* for younger members; and *Your Big Backyard* for preschoolers.

State wildlife federations and conservation leagues, made up of local clubs, are affiliated with the national organization. The federation has about 6 million members, counting members of affiliated organizations. The national group is financed by membership fees and the sale of nature-related items. The federation began in 1936. Critical reviewed by the National Wildlife Federation

**National Wildlife Refuge System** consists of over 450 refuges established by the United States government to protect and increase wildlife and their habitat. The refuge system covers over 90 million acres (35 million hectares). The smallest refuge is Mille Lacs National Wildlife Refuge, a 3 1/2 -acre (0.2-hectare) island in Minnesota. The largest refuge is Yukon Delta National Wildlife Refuge, which has almost 20 million acres (8 million hectares) in Alaska. The national refuges are managed by the U.S. Fish and Wildlife Service.

Each refuge has a specific purpose. Most were established to protect migratory birds. Some also protect species of wildlife in danger of becoming extinct. These species include bald eagles, brown pelicans, whooping cranes, sea turtles, and manatees. Refuges have played a major role in rebuilding the populations of buffaloes, elk, trumpeter swans, and pronghorns.

People also benefit from refuges. Refuges protect marshes, swamps, and other wetlands, which help con-

---

**Water birds** feed at St. Vincent National Wildlife Refuge near Apalachicola, Florida. The National Wildlife Refuge System has over 450 refuges that protect wildlife and their habitats.
trol flooding, filter pollutants, and refill the supply of underground water. Most refuges are open to the public, and many offer educational programs on protecting the environment. Hunting and fishing are permitted on some refuges, but these activities are strictly regulated.

The first wildlife refuge in the United States was established in 1903 on Pelican Island, off the east coast of Florida. President Theodore Roosevelt created this refuge to help protect brown pelicans and other birds that nest on the island. More refuges were set up through the years. In 1966, the U.S. Congress made these refuge areas the National Wildlife Refuge System.

National Zoological Park is a 163-acre (71-hectare) zoo maintained by the Smithsonian Institution along Rock Creek in Washington, D.C. The zoo exhibits about 5,000 animals of 500 different species (kinds). Wherever possible, animals, plants, and other living things are presented together in natural settings. Approximately 3 million people visit the zoo every year. National Zoological Park provides educational services to the public and conducts scientific research in animal behavior, ecology, zoo biology, animal reproduction, and exotic animal medicine. Conservation of endangered animal species is a major research focus.

Nationalism is a people’s sense of belonging together as a nation. It also includes such feelings as loyalty to the nation, pride in its culture and history, and—in many cases—a desire for national independence.

Since the late 1700’s, nationalism has become an important force in international relations. Nationalistic feelings, particularly the desire of each country to govern itself, have helped change the map of Europe several times since the 1800’s. Since the late 1940’s, nationalism has also transformed the maps of Africa and Asia.

Although nationalism is widespread today, it once did not even exist. People have not always had a sense of nationhood. Early people felt they belonged to cities or tribes. In the Middle Ages, people were loyal to a number of groups and rulers. For example, a French citizen might have owed loyalty to the duke of Burgundy, the king of France, the Holy Roman emperor, and the pope.

The rise of nationalism occurred along with the development of a political unit called the nation-state. A nation is a group of people who share a common culture, history, or language and have a feeling of national unity. A state is an area of land whose people have an independent government. A nation-state exists if a nation and a state have the same boundaries.

Nation-states began to develop during the late Middle Ages. Travel and communication improved at that time. As a result, people became increasingly aware of the part of their country that lay outside their own community. Loyalty to local and religious leaders began to weaken, and allegiance to kings grew stronger. By the 1700’s, England, France, Spain, and several other countries had become nation-states.

Other peoples developed a sense of nationhood by the early 1800’s. But most had not become nation-states. Many people believed that a national group had the right to form its own state. This belief, known as the doctrine of national self-determination, caused many nationalistic revolutions in Europe. For example, Greece won independence from the Ottoman Empire in 1829, and Belgium became independent of the Netherlands in 1830.

Different forms of nationalism later developed in various parts of the world. In the United States, the spirit of nationalism expressed itself in rapid westward expansion during the 1800’s. Many Americans became convinced that their nation had a manifest destiny—that is, a clear mission to take over all North America.

In Western Europe, new feelings of nationalism united the Italians and then the Germans, both of whom were still divided into many states. Each of these peoples combined to form one country out of the states. The unification of Italy was completed in 1870, and Germany became a nation-state in 1871.

In Eastern Europe, on the other hand, national groups sought to create smaller states out of the huge Austro-Hungarian, Ottoman, and Russian empires. These demands for national self-determination helped cause World War I (1914-1918) and broke up the empires after the war (see World War I: The rise of nationalism).

During the 1930’s, two dictators—Adolf Hitler of Germany and Benito Mussolini of Italy—used nationalism in demanding extreme loyalty from their people. They promoted integral nationalism, the belief that a certain nationality was superior to all others. This idea also placed strict limits on who could claim that nationality. In support of integral nationalism, the Nazis killed millions of Jews and other people they considered inferior. Germany and Italy also set out to conquer the world. Their actions helped bring on World War II (1939-1945).

After World War II, nationalism led many African and Asian colonies to demand self-government. India and Pakistan won independence from the United Kingdom in 1947. In 1948, a nationalistic movement called Zionism resulted in the establishment of Israel (see Zionism).

By the 1970’s, more than 80 other nations had become newly independent. Many of them lacked the long history of shared experiences that had produced nationalism in Europe. But their leaders encouraged nationalism to help develop national unity. In the early 1990’s, nationalism again contributed to the breakup of a number of states in Eastern Europe. These states included the Soviet Union, Yugoslavia, and Czechoslovakia.

Effects of nationalism can be both good and bad. Nationalism gives people a sense of belonging and pride and a willingness to make sacrifices for their country. They also take a greater interest in their nation’s achievements in such fields as literature and music.

But nationalism also produces rivalry and tension between nations. Desires for national glory and military conquest may lead to war. Extreme nationalism may result in racial hatred and in persecution of minority groups. Joseph S. Nye, Jr.

Nationalist China. See Taiwan.

Nationality, in law, is a person’s status as a member of a certain country. Usually, a person’s citizenship is the same as his or her nationality. But the terms do not mean exactly the same thing. For example, before the Philippine Islands became independent, their people were nationals of the United States. They owed alle-
giance to the United States but were not U.S. citizens.

Nationality is acquired at birth according to either of two principles. The first is the *jus sanguinis, or right of blood*, which gives to a child the nationality of one of the parents, usually the father. The second, called *jus soli, or right of the place of one's birth*, makes a person a national of the country in which he or she is born. Most countries use both principles. Every country has the right to determine who its nationals shall be.

**In the Commonwealth of Nations**, the difference between nationality and citizenship was once important. The Commonwealth is an association of mainly independent countries formerly under British rule. All people living in the Commonwealth were considered to be British subjects and citizens of their own countries. Today, however, citizens of Commonwealth nations are not considered British subjects. A British subject also may be a citizen of a Commonwealth nation if the subject meets that nation’s citizenship requirements.

**Nationality groups.** Nationality also refers to the fact that many people continue the habits, the customs, and even the language of their native land when they go to live elsewhere. Many groups of people in U.S. cities try to keep alive the customs and traditions of other countries. Some of these people were born outside the country. But in some cases, every member of the group was born in the United States. —Robert J. Pranger

See also Citizenship; Naturalization.

**Nationalization** is the control and ownership of an industry on a national scale by the government of a country. Industries that are most commonly nationalized include airlines, electric and gas utilities, mines, postal services, railroads, and telephone companies.

In some countries, nationalization plays a vital role in a set of economic, political, and social beliefs called *socialism*. These countries nationalize certain industries to provide better products or services for their citizens. Socialists say that nationalization ensures democratic control of these industries. In the past, Britain and France nationalized many industries for these purposes. But in recent years, political changes have resulted in the sale of many of the British and French industries to private investors. The selling of nationalized industries to private investors is called *divestiture* or *privatization*.

Other countries, especially some developing nations, have nationalized certain industries to remove them from foreign ownership. In the 1960's and 1970's, for example, some countries in the Middle East and elsewhere began to take over oil companies that had been owned chiefly by Americans or Europeans. These countries gained higher profits for themselves by removing the oil industry from foreign ownership.

**Forms of nationalization.** There are several forms of nationalization, based on how the nationalized industry is managed. In the most common form, a *public corporation* is set up as an independent body by law. The government appoints a board of directors that manages the industry. In another form, a government department has control of the industry. Such action gives the government close control of the industry. In a third form, the government buys part of the stock in an ordinary corporation, and private investors own the rest.

**Advantages and disadvantages.** Nationalized industries have some advantages over private industries. A nationalized industry can provide vital products or services to the public that would not be profitable for private industry to provide. The government can encourage a nationalized industry to invest and expand during an economic *recession* (slowdown). Nationalized industries can also develop weak parts of the economy and help hold down prices during periods of inflation.

Supporters of nationalization say that—in certain industries—a nationalized corporation can provide more efficient service than private industries. Such industries include electric and gas utilities and telephone companies. Supporters also say that government is too weak unless it has some control over vital industries.

Nationalization has some disadvantages. Many nationalized industries do not make a profit. As a result, the government uses money from taxes to *subsidize* (help pay for) them. Critics of nationalization charge that a lack of competition causes nationalized industries to become inefficient. They say government subsidies keep unprofitable industries alive even though the industries are no longer useful. Opponents also fear that too much power is concentrated in a government if it controls vital industries. —Dennis L. Thompson

**Natsume Soseki, NAHT SOH MEH SOH seh KEE (1867-1916),** was Japan's first great modern novelist. Soseki was a member of the first generation of Japanese youth exposed to Western books and ideas. His writing reflects his response to the problems of living in the modern world. He wrote about doubt and faith; self assertion and self questioning; alienation from industrial, mechanized society; and personal identity.

Soseki wrote 10 novels and several short stories. His first works were satires of the Japanese society of his time. He gained immediate fame with his first novel, *I Am a Cat* (1903). This episodic story is narrated by a cat who sardonically observes his master and neighbors. *Little Master* (1906) also indict modern society. The story is narrated by a country teacher whose old-fashioned virtues are of little use in his changing world. The best known of Soseki's later, and more somber, works is *Kokoro* (1914). The novel tells the story of a young man's relationships with an older man and his father, told partly through letters. His other novels include *The Three-Cornered World* (1906) and *Grass on the Wayside* (1915).

Soseki was born in Tokyo. His real name was Natsume Kinnosuke. He trained as a scholar of English literature, studying in England from 1900 to 1902. In 1907, he joined the staff of the *Asahi* newspaper, which published many of his novels in serial form.

Laurel Rasputic Rodd

**Natural gas.** See Gas (fuel).

**Natural gas liquids** are certain chemical compounds that can be obtained in liquid form from natural gas. These compounds rank among the world's most valuable energy resources. Natural gas liquids, also called NGL, are widely used as fuel, and in manufacturing petrochemicals and other products.

The chief NGL compounds, in order of increasing mo-
molecular weight, are ethane, propane, butane, pentane, hexane, and heptane. Chemical manufacturers use ethane in making ethylene, an important petrochemical. Butane and propane, and mixtures of the two, are classified as LPG (liquefied petroleum gas). LPG is chiefly used as a heating fuel in industry and homes. Pentane, hexane, and heptane are called natural gasoline or condensate. Refiners blend natural gasoline with other gasoline.

Natural gas liquids are classified as light hydrocarbons. Hydrocarbons, which occur in natural gas and petroleum, are a group of compounds that contain only the elements hydrogen and carbon. All hydrocarbons become liquid under certain combinations of temperature and pressure, depending on their molecular weight. Light hydrocarbons liquefy at lower temperatures and higher pressures than do heavy hydrocarbons.

There are two main methods of producing NGL, condensation and absorption. In condensation, natural gas is chilled until it becomes a liquid from which the NGL are extracted. In absorption, processors mix gas with an oil that absorbs light hydrocarbons. NGL are then distilled from the oil. Natural gas processing plants produce most NGL. The United States produces about 40 percent of all NGL.

See also Butane and propane; Ethane; Gas (fuel).

Natural history. See Nature study.

Natural number. See Number theory.

Natural resources are those products and features of the earth that permit it to support life and satisfy people’s needs. Minerals, land, and water are natural resources, as are such biological resources as flowers, trees, birds, wild animals, and fish. Mineral resources include oil, coal, metals, stone, and sand. Other natural resources are air, sunshine, and climate. Natural resources are used to make (1) food; (2) fuel; and (3) raw materials for the production of finished goods.

This article discusses natural resources in general. For information on the natural resources of specific areas, see the Natural resources section in each state and province article, and in various country articles.

Uses and importance. Biological resources are the most important natural resources. All the food we eat comes from plants or animals. Since early days, people have used wood from trees for fuel and shelter. Biological resources, in turn, are dependent on other natural resources. Most plants and animals could not live without air, sunshine, soil, and water.

Mineral resources are also extremely important to modern living. Mineral fuels—including coal, oil, and natural gas—provide heat, light, and power. Minerals serve as raw materials for making finished goods, such as cars, plastics, and refrigerators.

Natural resources contribute—but are not essential—to a nation’s wealth. Such wealthy nations as Canada and the United States are rich in natural resources. But some less-developed nations, such as Denmark and Japan, have few of them. Some poor, or less-developed, countries have few natural resources, though some, like Peru and Congo (Kinshasa), have many.

Conservation and development. Because modern civilization—even life itself—depends on natural resources, many people have been concerned about whether there will always be enough.

Scientists and economists believe that people can never use up all the mineral raw materials like iron, aluminum, sand, and fertilizer. There are sufficient quantities in the land and the sea, and most of the materials can be reused. For example, scrap iron can be melted down and used again in steel making. But people may have to explore farther and dig deeper to get what they need. Or they may have to substitute one material for another that has become too scarce. For example, aluminum may be used in place of copper for many purposes. While copper is scarce, deposits of bauxite and clay contain more aluminum than people can ever use.

Mineral fuels are different and can all be used up. The earth contains enough mineral fuels to last only one or two centuries at current rates of use. When these supplies run out, people may depend more on solar energy to power autos and factories and on nuclear energy to heat homes. Even today, uranium and other nuclear fuels generate electric power. Such fuels will last for many centuries. Sunlight is already used to run the instruments in space satellites and may someday be widely used to provide energy. Scientists are now trying to generate power by combining the nuclei (cores) of hydrogen atoms. This process, called nuclear fusion, is a potentially limitless source of energy.

Preserving the delicate balance of nature in biological resources appears to be the most difficult and important part of saving our natural resources. People have often upset this balance. For example, poor farming methods have ruined much farmland and left it barren. Each year, millions of tons of fertile topsoil that could produce good crops are washed away by rains. Chemicals sprayed on crops and washed off by rain sometimes end up in rivers and streams. Some of these chemicals kill the fish in the streams. Some entire species of birds and animals have been killed off by hunters.

Fumes from automobiles and trucks and smoke from factories poison the air. This air pollution in many cities kills trees and endangers human health. As more cars and factories are built, the problem tends to get worse. To correct these conditions, people have to reduce the amount of pollution produced by factories and automobiles. In the United States, the quality of both air and water has improved significantly since the 1970s because of government regulations. See Air pollution.

If natural resources are conserved and developed, Earth could not provide enough food if the population increases too much. With much effort, the amount of land under cultivation could be doubled, and farms in many developing countries could produce three or four times as much as they now do. Improved crop varieties can greatly increase yields. All this might increase the food supply 5 to 10 times what it now is. But eventually the growth of world population must slow if everyone is to have enough food.

Natural selection is a process in nature by which the organisms best suited to their environment are the ones
most likely to leave offspring. This process has been called survival of the fittest, though a more accurate term would be reproduction of the fittest. The theory of natural selection was first explained in detail in the 1850s by the British naturalist Charles R. Darwin. He believed all plants and animals had evolved—that is, developed by changing over many generations—from a few common ancestors by means of natural selection. Plants and animals produce many offspring, but some of the young die before they can become parents. According to Darwin’s theory, natural selection determines which members of a species die prematurely and which ones survive and reproduce.

The theory of natural selection is based on the great variation among even closely related individuals. In most cases, no two members of a species are exactly alike. Each has a unique combination of such traits as size, color, and ability to withstand cold or other harsh conditions. Most of these traits are inherited.

Only a limited supply of food, water, and other necessities of life exists for all the organisms that are produced. Therefore, the organisms must constantly compete for these necessities. They also struggle against such dangers as being destroyed by animals that prey on them or by unfavorable weather. In any environment, some members of a species have combinations of traits that help them in the struggle for life. Other members have traits that are less suitable for that environment. The organisms with the favorable traits are most likely to survive, reproduce, and pass on those traits to their young. Organisms that are less able to compete are likely to die prematurely or to produce few or inferior offspring. As a result, the favorable traits replace the unfavorable ones in the species.

If the environment changes, different traits or combinations of traits may become favorable to survival, and the overall character of a species might change. In this way, a species adapts to its environment and avoids extinction. If two populations of a species live in different environments, they will probably develop differently. Eventually, they may differ so much that they become two separate species.

In 1858, Darwin and another British naturalist, Alfred R. Wallace, presented similar theories of natural selection. Many biologists rejected the idea at first. They incorrectly thought that natural selection and evolution would eventually stop because a species would have used up all its possible variations. Since then, scientists have learned that the cells of every living thing have tiny structures called genes, which determine the organism’s hereditary traits. An organism inherits a set of genes from each parent. Variations occur in part because genes for new traits are constantly being introduced into a species and shuffled among individuals by reproduction. See Gene; Heredity (Heredity and natural selection).

Virtually all biologists believe that natural selection is an important process in evolution. But some religious groups reject the theory because it conflicts with their beliefs about the creation of life.

Jerry A. Coyne

See also Evolution; Darwin, Charles; Races, Human (Natural selection); Wallace, Alfred R.

Naturalism, in literature, is the attempt to apply scientific theory and methods to imaginative writing. Naturalists concentrate on the physical world to the exclusion of the supernatural. Naturalism thrived in the late 1800s and early 1900s and has been most important in the novel and in drama.

Theory of naturalism. Naturalists have been the most uncompromising realists. They believe that knowledge is acquired through the senses, and that the function of the writer is to report accurately what he or she observes. The naturalist tries to be as objective as a laboratory scientist. In their theory of life, naturalists are more pessimistic than realists. The realist believes people can make moral choices, but the naturalist doubts that they can. Naturalists believe everyone people do is determined by their heredity, or environment, or both. Naturalists believe people are trapped by forces such as money, sex, or power.

In picturing people as trapped, the naturalist usually deals with the more sordid aspects of life. Characters in naturalistic literature are driven by their most basic urges. They are often brutal and usually failures. They use coarse language, and their view of life is often bleak and without hope. Yet in the best naturalistic works, there is a tone of compassion and even admiration for those characters who struggle against overwhelming odds.

Naturalism in fiction. The principles of naturalistic fiction were first stated by the French author Émile Zola in The Experimental Novel (1880). Zola argued that novelists should treat their material as scientists treat theirs. Before 1880, psychological and physiological studies such as Zola recommended had appeared in works by Honoré de Balzac, Jules and Edmond de Goncourt, Gustave Flaubert, and other French writers. Zola’s books shocked English and American readers, but his theories and novels established naturalism as an important literary movement.

Naturalism never became popular in England, but it has been a major influence in the United States since the 1890s. Stephen Crane, Hamlin Garland, and Frank Norris were the first Americans consciously to adopt the naturalistic style. Jack London and Edith Wharton developed it further. Most critics, however, consider Theodore Dreiser the best American naturalist. Dreiser’s novel An American Tragedy (1925) is a moving account of a young man trapped by circumstance. Later American naturalistic novelists include Nelson Algren, John Dos Passos, James T. Farrell, Norman Mailer, and Richard Wright.

Naturalism in drama has the same goals as naturalism in fiction. A highly realistic setting provides a sense of environment overwhelming the characters. The staging, acting, and plots try to resemble life, not art. Everything focuses upon the hopeless, but often admirable, struggle of the characters against fate.

Zola also led the movement in drama with his adaptation of his novel Thérèse Raquin into a play in 1873. August Strindberg of Sweden and Gerhart Hauptmann of Germany rank among the best European naturalistic playwrights. Strindberg’s The Father (1887) and Miss Julie (1889) are two violent studies of sex. The Weavers (1893) by Hauptmann, a grim portrait of a workers’ revolt, set the style for German naturalism. Naturalism also appears in plays by Henrik Ibsen of Norway and Leo Tolstoy and Maxim Gorki of Russia.
In the United States, naturalism became most popular and important in the plays of Eugene O'Neill. Many of O'Neill's plays, especially the trilogy *Mourning Becomes Electra* (1931), have pathetic characters and depressing atmosphere. Other American playwrights whose works contain naturalistic elements include Arthur Miller, Clifford Odets, and David Mamet.

Naturalism today has declined in influence, but its methods and its view of life are responsible for much of the imaginative power in today's fiction and drama. Excessive though naturalism may have been in its hopelessness and brutality, modern literature reveals life more honestly because of it.

Lawrence Lipking

Each person mentioned in this article has a separate biography in *World Book*.

**Naturalist.** See *Nature study* and its list of Related articles.

**Naturalization** is a legal process by which a person becomes a citizen of an adopted country. Some nations, including Canada and France, give naturalized citizens the rights and duties of citizens by birth. Naturalized citizens of the United States cannot become president or vice president, but they have all the other rights and duties of people born as U.S. citizens.

A nation's naturalized citizens have the right to the protection of their adopted government when they travel abroad. However, some nations do not grant the right to give up citizenship. Such a nation could claim as a citizen any person who returned after being naturalized by another country. The adopted government might not be able to protect the individual in this situation.

Naturalization laws differ from nation to nation. For example, foreigners cannot be naturalized in the United States or Canada unless they have lived in their new country for a certain number of years. Israel, however, allows Jews from another country to be naturalized on the day they arrive. Many nations naturalize only people who understand the rights and obligations of citizenship and can use the national language. In many countries, foreigners who meet the requirements for citizenship take part in a naturalization ceremony. This ceremony includes an oath of loyalty to the adopted nation. In the United States and other countries, the oath of loyalty includes giving up citizenship in any other nation.

A special act by a government may naturalize groups of people without requiring them to follow the usual naturalization procedure. For example, an act by the U.S. Congress naturalized the people of Puerto Rico in 1917. The United States had gained Puerto Rico following the Spanish-American War (1898). Treaties also may include naturalization provisions.

**Naturalization in the United States**

The Immigration and Naturalization Service administers naturalization in the United States. The present naturalization law took effect in 1952. Until then, a person had to submit a declaration of intention to become a naturalized U.S. citizen. This declaration, sometimes called *first papers*, was required at least two years before the next step could take place.

The naturalization process consists of three steps: (1) an application, (2) an examination, and (3) the final hearing. Some states still require foreigners who plan to practice certain professions, including medicine and law, to submit first papers. However, these declarations are not part of the naturalization process.

**An application** must be submitted to an office of the Immigration and Naturalization Service. Applicants also must submit a fingerprint card and a biographical information form. The necessary forms and other materials may be obtained from offices of the Immigration and Naturalization Service, from naturalization courts, and from many social service agencies.

**An examination** of the applicant's qualifications for citizenship takes place after the application has been processed. Immediately before the examination, the applicant prepares and submits a *petition for naturalization*. The applicant, accompanied by two U.S. citizens who serve as witnesses, then appears before an officer of the Immigration and Naturalization Service. The witnesses testify to help the officer determine whether the applicant qualifies for citizenship.

Applicants must prove their qualifications in three areas: (1) age and residence, (2) character and loyalty, and (3) education.

**Age and residence.** Applicants must be at least 18 years old. They must have legally lived in the United States as permanent residents for at least the previous five years. Husbands and wives of U.S. citizens may qualify after a three-year residence. Short trips abroad, as well as longer trips for certain purposes, may be taken during the required period of residence. All applicants must have lived in the state where they seek naturalization for at least the previous three months.

**Character and loyalty.** Applicants must prove that they have lived by generally accepted moral standards throughout the last five years. They must follow these standards until naturalization has been granted.

The U.S. naturalization laws specify a number of practices that disqualify applicants on the basis of moral standards. These practices include habitual drunkenness or gambling, lying to gain benefits under immigration or naturalization laws, and crimes involving drugs or sex. No person who has ever been found guilty of murder can become a naturalized citizen of the United States.

Applicants must prove their loyalty to American principles of government. During the previous 10 years, they must not have willingly supported the Communist Party or any other organization considered disloyal.

**Education.** During the examination, applicants must read, write, and speak English unless a physical disability prevents them from doing so. Certain elderly persons are excused from this requirement. All people applying for U.S. citizenship must show that they have a basic knowledge of the history and the form of government of the United States.

**The final hearing.** After the examination, naturalization officers may request additional evidence of an ap-
Applicants and their citizenship.

The final hearing is held at least 30 days after the petition for naturalization has been filed. The hearing takes place in a court authorized to grant citizenship. In most cases, a naturalization officer tells the judge whether the applicant has been recommended for naturalization, and the judge does not interview the person. An applicant who fails to win recommendation for citizenship may dispute the officer's findings, perhaps with help from a lawyer.

If the judge decides to grant citizenship, the applicant takes an oath of loyalty to the United States. The oath includes giving up any foreign citizenship and all loyalty to any other country. It also includes a promise to obey orders from the government to serve in the U.S. military forces. However, an applicant whose moral beliefs forbid bearing arms in war is excused from this promise.

After taking the loyalty oath, applicants receive certificates of naturalization and are considered citizens. In certain cases, children who are under the age of 18 automatically become citizens of the United States if at least one parent is naturalized. Parents may obtain citizenship certificates for such children. Applicants who are not granted citizenship in the final hearing may appeal to the next higher court.

Naturalization in Canada

Unlike the United States, Canada allows naturalized citizens to remain citizens of their native country. The registrar of Canadian citizenship, an official of the Department of the Secretary of State, issues certificates of citizenship. About 130,000 persons are naturalized in Canada yearly.

There are three steps in Canada's naturalization process. These steps are: (1) an application, (2) a hearing, and (3) a citizenship ceremony.

The application is submitted to a citizenship court. Application forms can be obtained from citizenship courts, superior county courts, and provincial courts, and from the registrar of Canadian citizenship.

The hearing takes place before a citizenship examiner. Applicants must prove that they qualify for citizenship. They must be at least 18 years old and must have legally lived in Canada as permanent residents for three of the previous four years. Applicants must show that they can use French or English well enough to be understood in their community. They also must demonstrate a basic knowledge of the history, government, and geography of Canada.

If the examiner approves the application, the person takes an oath of citizenship at a special ceremony. The applicant swears to remain loyal to the monarch of Canada, who is the king or queen of England. In addition, the individual promises to obey the laws of Canada and fulfill the duties of Canadian citizenship. The applicant receives a certificate of citizenship at this ceremony.

History

Until the 1800's, few people became citizens by naturalization. In general, citizenship in a city or nation was acquired only by being born there or by being the descendant of a citizen. However, the ancient Romans naturalized many of the peoples whom they conquered. The British government provided for the naturalization of settlers in the American Colonies through the Plantation Act of 1740.

During the late 1700's and the 1800's, a number of nations began to grant citizenship by naturalization. Millions of people were leaving their native countries to settle in the New World. Many of them wanted the full rights of citizenship in their new land.

The spread of democracy, which emphasized equality among people, also encouraged nations to grant citizenship more freely. During the late 1800's, some nations began to allow naturalized American citizens to give up citizenship in the country of their birth. People who gave up their citizenship in these countries could return to visit their homelands without fear of being claimed as citizens.

Since 1900, increasing international travel has resulted in easier naturalization procedures. Many people have no connection with the country of their birth. Many others are the children of immigrants and have no link with their parents' former country. In 1948, the United Nations stated in its Universal Declaration of Human Rights that people have the right to change citizenship.

Nature Conservancy is an international conservation organization that saves rare plants and animals from extinction by protecting the places where they live. One of the many ways that the organization accomplishes this goal is to acquire land, which it purchases or receives as a gift.

With 1,200 preserves, the Nature Conservancy owns and manages the largest private system of nature sanctuaries in the world. Its Pine Butte Swamp Preserve in western Montana contains the site of the world's first discovery of baby dinosaurs in nests.

The Nature Conservancy was founded in 1951. Since then, it has protected more than 5 million acres (2 million hectares) of critical habitats in the United States. The Nature Conservancy has also helped preserve several million acres in Latin America, including tropical rain forests. The organization has more than 550,000 members. It publishes The Nature Conservancy Magazine, a journal issued six times a year. The organization's headquarters are in Arlington, Virginia.

Critically reviewed by The Nature Conservancy

Nature study means watching and learning about things in nature. Students of nature may go on hikes in the countryside to observe the birds or to look for wildflowers. In the city, nature lovers may visit gardens, museums, parks, and zoos to learn about the natural world. Many youth organizations have nature study programs. Such organizations may sponsor outings or carry out special projects for the protection of the natural environment.

Careful observation is necessary in nature study. Many naturalists (students of nature) keep detailed records of their observations in the form of notes, sketches, or photographs. Some students of nature collect such things as flowers, insects, leaves, rocks, or shells. Natu-
nalists have made many important contributions to our understanding of nature.

Nauru, NAH roo, is a small island country in the central Pacific Ocean. It is part of Micronesia, one of the three groups of the Pacific Islands. Nauru consists of a single island, which has an area of only 8 square miles (21 square kilometers). It is the third smallest country in the world. Only Vatican City and Monaco are smaller. Nauru is rich in phosphates—valuable chemical compounds used in making fertilizers. Phosphate exports earn a large part of the Nauruan government's revenue.

Nauru has no capital city. The main government offices of the country are located on the southwestern part of the island. The Australian dollar is Nauru's basic unit of currency. For a picture of the flag of Nauru, see Flag (picture: Flags of Asia and the Pacific).

Government. Nauru is a republic and a member of the Commonwealth of Nations. An 18-member Parliament makes the country's laws. Parliament members are elected by the people to three-year terms. All Nauruans who are 20 years old or older may vote. The Parliament elects a president to a three-year term. The president selects a Cabinet. The president and the Cabinet carry out the executive functions of the government.

Land. Nauru, an oval-shaped coral island, lies about 40 miles (65 kilometers) south of the equator. Most of the island is a plateau, 200 feet (61 meters) high, which contains deposits of phosphates. Near the center of the plateau is a lagoon surrounded by a small area of fertile land. Another belt of fertile land lies along the coast.

Most of the people live along the 12-mile (19-kilometer) coastline. In the past, the people raised their own food. Now, they import most of their food and other products they need. Nauru has a tropical climate that is cooled by trade winds. Temperatures range from 76 °F (24 °C) to 93 °F (34 °C). About 80 inches (200 centimeters) of rain falls yearly.

People. About half of Nauru's population of 12,000 are Nauruans—people of mixed Polynesian, Micronesian, and Melanesian ancestry. They are Christians. Most of them speak both the Nauruan language and English. The rest of Nauru's people are from Kiribati, Tuvalu, China, and Australia. They come for limited periods of time to help mine the phosphates.

The government provides Nauruans with modern homes at low rents, and 2 government hospitals and 11 clinics give them free medical care. The law requires Nauruan children between the ages of 6 and 17 to attend school. Nauru has five nursery schools, an elementary school, a high school, a Roman Catholic mission school, and a teacher training college. The government pays the expenses of students who attend universities in other countries.

Economy. Phosphates are Nauru's only important resource and its only export. A government-owned shipping company in Nauru serves many regions in the Pacific Ocean. A government-owned airline provides service to many Pacific areas. Nauru's government encourages such local industries as fishing and canoe building. Products that are imported include automobiles, food, furniture, machinery, medicine, and shoes.
Nauru also imports water for its needs.

History. Captain John Fearn, an English explorer, was the first European to visit Nauru. He came in 1798. In 1888, Germany took over the island and administered it until 1914 when Australia took control. After World War I (1914-1918), Australia began to administer the island under a League of Nations mandate held also by Britain, Australia, and New Zealand.

Japan seized Nauru during World War II (1939-1945). In 1945, Australian forces retook the island. In 1947, the United Nations (UN) provided for Australian control of the island under a trusteeship held also by Britain, Australia, and New Zealand. In 1964, Nauru began to work for independence and control of the phosphate industry. Nauru became independent in 1968 after a UN-supervised plebiscite (popular vote). In 1970, the Nauruan government gained control of the phosphate industry. Since then, the government has used revenue from phosphate exports to build homes, schools, and hospitals. It has also saved and invested much of the revenue to help support the Nauruan people after all the phosphates have been mined. Michael R. Ogden

**Nausea, NAW shuh or NAW shee uh**, is a disagreeable sensation in the area of the stomach. It is often followed by vomiting. In nausea, the muscles of the stomach wall slow or stop their movement. In turn, digestion of the contents of the stomach slows or stops. This action can help prevent the body from absorbing a poisonous substance that has been swallowed. If vomiting takes place, most of the substance will be expelled.

Nausea also may result from many other causes, both mental and physical. Mental causes of nausea include unpleasant sights, disgusting odors, and severe anxiety. Physical causes include severe pain, obstruction or irritation of the digestive tract, excessive physical exercise, and unnatural stimulation of the **vestibular system**, the organs of balance of the inner ear. Nausea that results from disturbances of the vestibular system is called **motion sickness** (see Motion sickness). Nausea often accompanies pregnancy, especially in the mornings of the first three months.

Some poisonous substances cause nausea by stimulating nerve endings in the lining of the stomach or intestine. Other poisons cause nausea after being absorbed into the blood. The blood carries the poison to special cells in the **medulla**, the lower part of the brain stem. These cells cause nausea by sending impulses to higher parts of the brain, where sensations are received. Various drugs, including chlorpromazine and Dramamine, are used to control certain types of nausea (see Chlorpromazine; Dramamine). K. E. Money

**Nautical mile.** See Knot; Mile.

**Nautical terms.** See Ship.

**Nautilus.** See Submarine (early submarines; Nuclear submarines); Connecticut (picture: The Nautilus).

**Nautilus, NAW tuh luhs,** is a marine animal whose soft body is partly covered with a coiled shell. The nautilus belongs to the same class of animals as the squid and octopus. A nautilus shell contains about 30 chambers which are lined with a rainbow-colored substance called **mother-of-pearl** or **nacre**. Because of this substance, the animal is often called a **peary nautilus**. The nautilus lives at depths of 20 to 1,000 feet (6 to 300 meters) in the South Pacific and Indian oceans. It eats crabs and other crustaceans. About six species of nautilus are living today. At least 2,000 fossil forms are known.

The body of a full-grown nautilus is about the size of a person's fist. Its cone-shaped head is surrounded by about 90 short tentacles (feet). As the animal grows, its shell develops in the form of a spiral. The nautilus adds a new chamber to its shell each time it outgrows its old one. Each new chamber is closed at the rear, so the animal always lives in the outermost chamber of its shell. The closed chambers behind the animal are filled with nitrogen and other gases. The siphuncle, a coiled, blood-filled tube that is enclosed in a limy covering, extends through all the chambers of the shell.

**Scientific classification.** The nautilus is in the phylum Molusca. It belongs to the nautilus family, Nautilidae. The pearly nautilus is **Nautilus pompillius**. Robert Robertson

See also Argonaut; Shell (Octopuses and squids; pictures: Nautilus shell).

**Navajo Indians, NAV uh hoh,** also spelled Navaho, are the second largest Indian tribe in the United States. Only the Cherokee tribe has more members. The Navajo reservation, which covers 16 million acres (6.5 million hectares), is the nation's biggest reservation. It includes parts of Arizona, New Mexico, and Utah. The growth of industry on the reservation promises to make the Navajo one of the wealthiest tribes in America. The Navajo call themselves **Diné** (pronounced **dih EH**), meaning the people.

About 150,000 Navajo live on the Navajo reservation. Some of the people live in traditional tribal houses called **hogan**s, which are made of earth and logs (see Hogan). Many Navajo practice the tribal religion. Large numbers of the tribe are farmers or sheep ranchers, but others are engineers, miners, teachers, or technicians. Skilled Navajo craftsmen weave wool blankets and make turquoise jewelry. The Navajo earn millions of dollars yearly, mainly from the mining of their vast coal deposits. The tribe also has a lumber mill and a manufacturing plant leased by an electronics firm. Navajo Community College, the first college owned and oper-
ated by Indians, is in Tsailé, Arizona, near Lukachukai, on the reservation.

About A.D. 1000, the ancestors of the Navajo migrated to the southwestern United States from what is now Alaska and Canada. Their Pueblo neighbors taught them to raise crops. During religious rituals, Navajo medicine men and medicine women created symbolic sand paintings to help heal the sick (see Sand painting).

During the 1600’s, the Navajo began to raise sheep. An increasing number of white settlers established ranches on the Navajo lands, and the Indians fought to drive the ranchers away. In 1864, U.S. Army troops led by Kit Carson destroyed the farms and homes of the Navajo. The soldiers forced about 8,000 Indians to march more than 300 miles (480 kilometers) to Fort Sumner, New Mexico. The Navajo call this march the "Long Walk." Thousands of Indians died during the march and their imprisonment at the fort. In 1868, the Navajo agreed to settle on the reservation.

The Navajo reservation surrounds the Hopi Indian Reservation. The two tribes have disagreed over land ownership and use for many years, and the U.S. government has tried to solve some of these disputes. In 1974, Congress gave each tribe half of a 1,800,000-acre (730,000-hectare) land area in Arizona that the tribes had used jointly since 1962. However, many members of the Navajo tribe refused to move off the Hopi land. In the early 1990’s, the Navajo and Hopi tribes reached an agreement, allowing Navajo families to remain on Hopi land for 75 years, living under Hopi law. Congress ratified this agreement in 1996. By the early 2000’s, most Navajo families had either moved off Hopi land or had signed an agreement with the Hopi tribe. Delilah Orr

Naval Academy, United States. See United States Naval Academy.

Naval Observatory, United States, is the country’s oldest national observatory. It was founded in 1830 and is operated by the U.S. Navy. It includes a main station in Washington, D.C., and substations in Flagstaff, Arizona; Richmond, Florida, near Miami; and Black Birch, New Zealand. It also operates radio telescopes in Green Bank, West Virginia.

The United States Naval Observatory is responsible for measuring the positions and motions of the sun, moon, planets, and stars, and for monitoring the position of the earth. It also maintains the U.S. reference for precise time. The observatory distributes its data through such means as almanacs and related publications, electronic data links, and satellites. Information from the observatory is used by U.S. and international civilian and scientific agencies, primarily for navigation and scientific research.

The observatory’s largest telescope, located in Flagstaff, is a reflecting telescope with a diameter of 61 inches (155 centimeters). In 1978, this instrument was used to discover Pluto’s only known satellite, since named Charon. A 26-inch (66-centimeter) refracting telescope, now located in Washington, D.C., was used to discover the two moons of Mars in 1877.

Critically reviewed by the United States Naval Observatory

Naval War College, in Newport, Rhode Island, is the postgraduate educational institution of the United States Navy. The college improves the professional decision-making abilities of senior officers in both command and management positions in the United States Navy. It also conducts research aimed at developing strategies and tactics for use in future naval warfare.

The Naval War College consists of four resident colleges and the Center for Naval Warfare Studies. Two resident colleges train U.S. officers from all branches of the armed forces. The other two train officers from other countries. The Center for Naval Warfare Studies coordinates research and computerized war games. War games train officers to make decisions in battle by imitating actual combat conditions. Commodore Stephen B. Luce founded the Naval War College in 1884.

Navigation is the process of determining a vehicle’s position and directing its movement. Navigation is used chiefly to guide airplanes, ships, and spacecraft, but it also can be used for vehicles that travel on land. The word navigate comes from two Latin words meaning ship and to drive. Navigation involves many sciences, including astronomy, mathematics, and physics, and a variety of equipment.

Basic navigation aids include a chart and a compass. A chart shows the physical characteristics of an area and is used to plot a vehicle’s course and position. An aeronautical chart provides such information as the location of airports, the height of mountains, and the location of radio transmitters that aid navigation. A nautical chart provides the depth of the water, the location of buoys and lighthouses, and other sailing information. A navigator uses either a magnetic compass or a more complex electronic instrument called a gyrocompass. Gyrocompasses are more precise than magnetic compasses.

Vehicles also have such basic navigation aids as an extremely accurate timepiece called a chronometer and a device to determine speed. The speed gauge of a plane is known as an air-speed indicator. The one on a ship is a log and on a land vehicle is a speedometer.

There are five primary methods of navigation: (1) dead reckoning, (2) piloting, (3) celestial navigation, (4) electronic navigation, and (5) inertial guidance. A navigator uses one or more of these methods, depending on such factors as the type of vehicle and the weather.

Dead reckoning

Dead reckoning (DR) involves estimating a vehicle’s position by considering how far and in what direction it has traveled. This method is not extremely accurate. However, navigators generally use dead reckoning along with any of the other methods.

In dead reckoning, the navigator determines the vehicle’s position in relation to its last fix. A fix is a vehicle’s known position. Starting at the fix, the navigator draws a line on a chart that represents the direction and distance traveled by the vehicle. The vehicle’s DR position is at the end of this line. The navigator determines the direc-
tion with a compass. The distance is calculated by multiplying the vehicle's speed by the time traveled.

Dead reckoning does not consider such factors as current, steering errors, or the wind. Any of these factors may cause a vehicle to be at a location other than the calculated DR position. The navigator must then use a more accurate method to establish a new fix.

Dead reckoning helps the navigator keep track of a vehicle's position between fixes. It is also used to plot future positions and to estimate when the vehicle will arrive at its destination. Some large ships use a device called a dead reckoning tracer to plot their position electronically. The tracer monitors the ship's gyrocompass and log to ascertain the direction and distance traveled. This information is automatically and continually drawn on a chart or displayed on dials.

Piloting

In piloting, a navigator finds the position of a vehicle in relation to one or more landmarks. An up-to-date chart is a necessary aid. The chart shows the positions of natural landmarks, including mountains and islands, and of such artificial landmarks as buildings, buoys, and lighthouses. Piloting involves determining a landmark's bearing (direction) and distance from the vehicle.

A bearing is determined by using a compass or a pelorus. A pelorus is a compasslike device that measures the bearing of a landmark in relation to a ship. It has a circular face marked off in degrees and a sight vane that rotates above it. The navigator aims the sight vane at a landmark, and the bearing is shown on the face of the pelorus. A device called an azimuth circle can be attached to a compass and rotated like a sight vane to determine bearings. A hand compass can also be used.

The simplest method of piloting involves finding the bearings to two or more landmarks. A landmark's bearing is represented on a chart as a line called a line of position. The navigator determines the bearing of one landmark and draws a line of position from the landmark in the direction shown by the compass or pelorus. The vehicle's position is somewhere along this line. The navigator then ascertains the bearing of another landmark and draws a second line of position. The vehicle's location is the point where the two lines cross. Other methods of piloting include (1) observing the bearings of a single landmark at various intervals of time, and (2) observing when two landmarks lie on a single bearing.

Piloting can be used to navigate most types of vehicles. Ships use this method when entering or leaving ports, or when sailing close to land. Many small boats are piloted with only a chart and compass. Navigators may also use a depth finder, a device that measures the depth of the water. A navigator compares the depths indicated by this device with the depths on the chart.

Celestial navigation

Celestial navigation is a method of determining a vehicle's location by observing certain celestial bodies—the sun, the moon, the stars, and the planets. A publication called an almanac lists the positions of these bodies at all times during the year. Celestial navigation uses Greenwich Mean Time (GMT), the time in Greenwich, England (see Time Worldwide time zones).

There are many variations of celestial navigation. In one common method, the navigator finds a vehicle's position in relation to an assumed position (AP). An AP is a point chosen by the navigator that is at or near the vehicle's dead reckoning position.

To determine the position of the vehicle, the navigator uses a sextant. This instrument measures the angular distance of a celestial body above the horizon. Such a measurement is called the observed altitude of the body. The navigator then calculates the computed altitude, which is what the body's altitude would be if the vehicle were at the AP. The navigator finds the computed altitude by solving a mathematical problem involving a spherical triangle. The points of the triangle are (1) the AP, (2) the North Pole or the South Pole, and (3) the geographic position (GP) of the celestial body. The GP is the point on the earth directly beneath the body. The navigator finds the GP of the celestial body in the almanac.

A special calculator or a navigation aid called a sight reduction table can be used to solve the triangle and determine the computed altitude. The navigator then performs certain calculations to compare the computed altitude with the observed altitude. A computer program may be used to determine the computed altitude and to perform the calculations. The calculations place the vehicle on a line of position. A fix is established by repeating the process with one or more celestial bodies.

For most ships, celestial navigation can be used only when the sky is clear. Celestial navigation can be used on airplanes and spacecraft at any time these vehicles fly above the clouds. Submarines have a special navigation periscope that enables a navigator to view celestial bodies while the ship is underwater.

Electronic navigation

Various navigation systems are based on electronic devices, most of which use radio signals. Radio signals
A common method of celestial navigation

To find a vehicle's position, a navigator first chooses an assumed position (AP). An AP is a point that is at or near the vehicle's estimated location. The navigator then uses an instrument called a sextant, above left, to measure the angular distance between the horizon and a star or other celestial body. This measurement is called the star's observed altitude, above right.

Light rays from the star strike various points on the earth at different angles, above left. At the point directly beneath the star, the rays intersect the earth at an angle of 90°. This point is called the star's geographic position (GP). The GP, AP, and North Pole are the points of a spherical triangle, above right, which the navigator uses in calculating the star's computed altitude.

Determining the fix. The computed and observed altitudes are used to place the vehicle on a circle of position. The GP of the star is the center of the circle. Additional circles of position, involving observations of additional stars or other celestial bodies, are then established, above left, to determine the vehicle's location, or its fix. The navigator marks this position on a chart, above right.
vary in frequency, the rate at which a radio wave vibrates as it travels through air or space. High-frequency navigation signals generally can be used with great accuracy. However, high frequency signals cannot be transmitted beyond the horizon. Low-frequency signals usually are not as accurate in establishing position as are high-frequency signals, but they can be received thousands of miles away.

Common navigation systems that involve reception of radio waves include loran, omega, omnirange, and radio direction finding. In the United States, transmitters for these navigation systems are based on land, and most are operated by the government. Other systems that use radio signals include radar and satellite navigation. Radar equipment is carried aboard a vehicle or based on land. Satellite transmitters are based in space.

Loran is used to guide ships and some airplanes as they approach coastal waters from the sea. The word loran stands for long range navigation. A loran system uses two types of stations called a master station and a secondary station. Special equipment aboard a ship or a plane uses the low- or medium-frequency signals sent by these stations to establish a loran line of position. The location of a vehicle is at the point where the lines of position derived from two pairs of loran stations intersect on a chart. In most cases, a single master station is paired with each of two secondary stations.

The type of loran system used in the United States and Canada is loran-C. A loran-C signal has a range of more than 1,000 miles (1,600 kilometers) during the day. Under certain atmospheric conditions, it can be received more than 3,000 miles (4,800 kilometers) away at night, when low-frequency radio waves travel farther. A position can be located within 1/2 mile (0.4 kilometer). See Loran.

Omega is a worldwide navigation system for planes and ships. The system has eight transmitters located throughout the world and requires international cooperation to operate. Special equipment aboard a vehicle receives and processes the radio signals sent by two pairs of omega transmitters. This equipment establishes two lines of position for the vehicle. The vehicle's position is at or near the point where the lines of position cross.

Omnirange is a short-range navigation system for aircraft flying over land. A special receiver electronically traces the signal of an omni range transmitter to determine the bearing of the transmitter from a plane. The location of the transmitter is shown on the aeronautical chart. Many omni range stations also transmit signals for airborne distance-measuring equipment, which calculates a vehicle's distance from a transmitter.

Radio direction finding involves locating the bearing of a transmitter called a radio beacon. A radio beacon's signal is received aboard a vehicle by a device called a radio direction finder (RDF). The navigator turns the antenna of the radio direction finder to find the direction of the radio beacon. The RDF shows when the antenna is pointing toward the beacon.

Radio direction finding is one of the oldest electronic navigation systems for aircraft and ships. It is generally used as a piloting aid along coastal waters. The range of a radio direction finding signal depends on the type of radio beacon.

Radar is based on the transmission of radio signals toward an object and the reception of the signals that are reflected from the object. The return signals create an image on a radar screen, which shows the direction and distance of the object from the vehicle.

Radar has many uses in navigation. It helps a navigator carry out a piloting operation by locating the vehicle's position in relation to landmarks at night or in bad weather. Radar also is used to locate obstructions and to prevent collisions with other vehicles. In addition, navi-
The Global Positioning System includes satellites that circle the earth and broadcast their positions. A receiver can find its location by computing its distance from at least three satellites.

Navigators use radar to track the positions of airplanes, missiles, ships, and spaceships.

**Satellite navigation.** There are several satellite-based navigation systems. Probably the best known is the Global Positioning System (GPS), which became fully operational in 1993. The GPS contains 24 Navstar satellites, which are controlled by the U.S. Air Force. The word Navstar stands for Navigation Satellite Tracking and Ranging. The satellites circle the earth in six different orbits. Each satellite broadcasts its exact position and the time. A computerized receiver on a vehicle analyzes how long it takes the broadcast from at least three different satellites to reach it. The receiver then determines its location by calculating its distance from these satellites. The GPS enables all types of vehicles on the earth and in the air to find their position under all weather conditions. Handheld GPS receivers may also be used outside a vehicle.

**GLONASS,** a satellite navigation system controlled by Russia, also provides global positioning information. It consists of a constellation of 24 satellites.

**Inertial guidance**

Inertial guidance involves the use of a computer and a device called an inertial navigator. An inertial navigator constantly monitors changes in the vehicle’s motion and sends this information to the computer. The computer uses these changes, plus the distance and direction traveled, to calculate the vehicle’s course and position. Inertial navigation is used to guide aircraft and submarines. Some guided missiles also use this method. See **Inertial guidance.**

**History**

In ancient times, sailors navigated by observing various celestial bodies and constellations and by studying the seasonal directions of the wind. During the Middle Ages (A.D. 400’s-1500’s), navigators drew simple charts that included wind directions for different seasons, plus compass directions.

Many of today’s navigation instruments developed from crude equipment used hundreds of years ago. For example, the first compass consisted of a magnetized piece of metal on a straw. The straw floated in a container of water. The sextant developed from the astrolabe and the octant: two early instruments for measuring the angle between a celestial body and the horizon. An astrolabe consisted of a disk, plus a sight that turned on a pivot. An octant had the same arrangement of mirrors as a sextant.

In the 1700’s, James Cook, a British navigator, became the first person to use modern celestial navigation methods. Cook used these techniques in several voyages to the Pacific Ocean.

The development of radio, followed by its use on ships and airplanes in the early 1900’s, marked the start of electronic navigation. During World War II (1939-1945), German scientists developed navigation systems.

A compass rose, like this one on a 1612 map of Virginia, indicates direction. Lines radiate from it in 32 points of direction.

to guide V-1 and V-2 rockets. On the Allied side, British and American scientists made important advances in radar technology that aided navigation.

Satellite navigation began in 1960, when the United States Navy launched a satellite called TRANSIT IB. The TRANSIT satellite navigation system began daily operation in 1964. It consisted of seven operating satellites placed in widely spaced orbits, plus several spares. A computerized receiver could fix its position by analyzing the Doppler shift of the signals broadcast by any TRANSIT satellite as the satellite passed overhead (see Doppler effect). In the 1970s, the United States launched the first of several satellites of the Navstar Global Positioning System (GPS). The system became fully operational in 1995. The TRANSIT system was shut down in 1996.

Navigation Acts were several laws passed in the 1600's by the English Parliament. The purpose of the laws was to protect English trade. In 1645, Parliament passed a law that forbade the importation of whale oil into England in non-English vessels, or in ships that were not operated by English sailors.

The act known as the First Navigation Act was passed in 1651. It was aimed against the American Colonies and the Dutch, who were profiting from much of the overseas trade between the West Indies and Europe. The act provided that no products from any foreign country might be shipped into England in any but English-built ships operated by crews that were at least 75 percent English. But the act was not strictly enforced.

Parliament passed other trade laws in 1660, 1663, and 1672. The act of 1660 required that all the tobacco from the colonies must be brought to England. The act of 1663 (Second Navigation Act) declared that almost all goods imported into the colonies must be landed in England first. In 1672, an act was passed requiring that goods had to be shipped to England before they could pass from one of the American Colonies to another.

Before 1761, 29 acts limiting colonial trade had been passed. These included one law banning importation of molasses and sugar. America suffered little from these laws because of smuggling by the colonists. Several parts of the acts favored American industry, especially shipbuilding, because they encouraged American shipping. But the Americans vigorously opposed the restrictions on commerce. This opposition was one of the main causes of the Revolutionary War in America (1775-1783). The British Parliament, in 1849, repealed (canceled) all the Navigation Acts.

A naval task force consists of a temporary unit of ships formed to carry out an operation. In this British task force, a V/STOL aircraft carrier leads a group of smaller Royal Navy warships.

Navy

Navy is the branch of a nation's armed forces that consists of warships and support ships, their crews, and land bases and their personnel. Many navies also have an air force. Some navies include combat forces called marines, who are trained to fight in the air and on land.

Most nations that have a coastline have a navy. But the world's navies differ greatly in size, in fighting strength, and in the types of ships and aircraft that they have.

Smaller navies consist mainly of warships called small combatants, such as patrol boats, missile boats, and minesweepers. The main task of a small navy is to defend its nation's coastline. Larger navies also have major warships, such as aircraft carriers, submarines, and frigates. These warships can operate far out at sea without returning to port for weeks or months. Nations use large navies to control the sea and, during times of war, to attack enemy shores.

The United States and Russia have the world's largest navies. Other countries with large navies include Britain, China, France, and India. For centuries, the most powerful nations were often those with the strongest navies. The development of aircraft and missiles in the 1900's reduced the importance of seagoing forces. Nevertheless, navies still have tremendous military and political
value. Warships are flexible in operation, and they can travel the seas freely. International law allows ships to sail within 12 nautical miles (22.2 kilometers) of any country's coast without permission. Thus, a group of warships can serve as a temporary military base. More importantly, ships can carry out their mission independent of foreign land bases.

The role of navies

Nations use their navies in many different roles. A navy's role depends on its size and composition, and whether the nation is at war or at peace.

**Peacetime roles.** When a nation is at peace, it may show political support by sending its ships to an ally's port or by training with an ally's navy. Navies may also help deliver food, medicine, and other humanitarian aid to war-torn countries or to areas struck by a natural disaster. In addition, nations may use their navies to collect intelligence (information about potential enemies).

Sometimes, navies perform limited military operations during peacetime. For example, in the late 1980s, U.S. warships escorted oil tankers in the Persian Gulf to protect them from attack during the war between Iran and Iraq. This was a military action, even though the United States was not directly involved in the war.

**Wartime roles.** During a war, the primary role of a small navy is to defend its nation's coastline against enemies. Large navies have two principal wartime roles: (1) controlling the sea and (2) providing a base from which to launch attacks against the shore.

Controlling the sea means that a navy takes over specific areas of the ocean to ensure the safe passage of its own ships and to deny passage to enemy ships. Control of the sea involves defending ships against attack. It also may involve blockading enemy land bases so that enemy ships and aircraft cannot use them. A navy may control some areas of the sea by laying naval mines (explosive devices in the water). Naval mines can damage or destroy ships that try to pass over them.

A nation with a large navy also has the power to attack targets on land from the sea. Modern warships can launch attacks from positions far out at sea using missiles and aircraft. Navies may also launch amphibious assaults—invasions of enemy coastal areas by the combined action of land, sea, and air forces.

The organization of navies

Every navy has a shore-based branch and a seagoing branch. The shore-based branch includes headquarters, communications stations, airfields, shipyards, maintenance facilities, supply stations, naval schools, and their personnel. The seagoing branch, usually called the fleet, consists of a navy's ships, submarines, ship-based aircraft, and their crews. The organization of a fleet varies with the size, mission, and location of the navy. The U.S. Navy, for example, has separate fleets in the Atlantic and Pacific oceans. France has Atlantic and Mediterranean fleets. India's navy operates one fleet on India's western coast and a second fleet on its eastern coast.

Because ships are flexible in their operation, they can be organized in many combinations for different purposes. In most fleets, each ship is assigned to a permanent administrative unit called a group, squadron, or division. Large fleets may also organize their ships into task forces. These are temporary groupings of ships formed to carry out a particular task. A task force may consist of one or more than a dozen ships, depending on the task. In the U.S. Navy, task forces are called battle groups when they contain one or more aircraft carriers.

**Ships and aircraft**

The world's navies operate many types of ships, ranging from huge aircraft carriers to small patrol boats. Navies also use many kinds of aircraft.

**Navy personnel** may be assigned to ships or bases on shore. This German naval officer serves aboard a small ship. From the bridge (navigational center), he watches a nearby auxiliary ship.

**Chinese sailors** on the deck of a destroyer prepare a guided missile for launching. The large Chinese Navy operates mostly in coastal waters.
Aircraft carriers are the largest warships ever built. Carriers serve as mobile bases for many kinds of aircraft. Some carriers are designed for conventional aircraft, which would normally require a long runway. Conventional aircraft are launched from a carrier deck with the aid of a catapult. When the aircraft land, a device called a tail hook lowered from the rear of the plane catches one of the steel cables stretched across the deck. Only the Brazilian, French, Russian, and U.S. navies have conventional aircraft carriers.

Other carriers can serve as a base only for V/STOL aircraft, which take off vertically or from a short runway. V/STOL stands for vertical/short take-off and landing. Several navies have V/STOL carriers. Helicopters fly from both types of carriers.

Most carriers are armed with guns and missiles for short-range defense, but they depend on their aircraft and other warships for protection. Russian carriers are more heavily armed than carriers in other fleets.

Cruisers are the next largest warships. Navies use cruisers primarily to defend aircraft carriers against air and submarine attacks. Cruisers are armed with missiles, rockets, and torpedoes. Some cruisers also carry powerful long-range missiles for attacking targets on land. Only France, Italy, Peru, Russia, and the United States have cruisers.

Destroyers are similar to cruisers, but they are smaller and less costly to build. They are armed with guns, rockets, torpedoes, and missiles. A destroyer’s main role is to escort and defend other ships, but destroyers also perform independent missions. Several of the world’s navies have destroyers.

Frigates are the most common large warship in the world’s navies. Navies use them chiefly to defend other warships and cargo ships against enemy submarines. Frigates are armed with torpedoes and other antisubmarine weapons. Most frigates also have guns, and some have missiles for defense against air and surface attacks.

Amphibious ships—often called amphibs—carry marines to enemy shores for operations on land. Amphibs use helicopters and landing craft to carry troops and their equipment ashore.

Submarines are warships that travel underwater. They can remain at sea, fully submerged, for long periods. They are extremely difficult for enemies to attack. Navies have two principal kinds of submarines: attack submarines and ballistic missile submarines. Attack subs-
India enlarged its navy during the 1980's as part of an arms build-up. India now has about 25 surface warships, including 1 conventional aircraft carrier. The Indian Navy's 16 submarines are all diesel-powered. About 53,000 people, including marines, serve in the Navy.

France has a small but modern, well-trained, and effective navy. It has about 35 surface warships, including 1 conventional aircraft carrier. France also has 11 submarines, 10 of which are nuclear powered. About 50,000 people serve in the French Navy, including marines.

The United Kingdom has a small but effective navy. The navy of the United Kingdom, called the Royal Navy, operates about 35 surface warships, including 3 conventional aircraft carriers. The Royal Navy also has 16 submarines, all of which are nuclear powered. About 44,000 people, including marines, serve in the Royal Navy.

The history of navies

Ancient navies. By about 3000 B.C., the Egyptians were using small seagoing ships for military purposes. Between 2000 and 1000 B.C., the Greeks began building long, wooden ships called galleys. Galleys were propelled chiefly by oars, but most also had sails. Ancient Mediterranean civilizations used galleys to guard their coastlines and trading ships. Ancient galleys had pointed bows to ram other ships. Later, crews used catapults (weapons that resembled giant slingshots) to throw stones, hot coals, and pitch onto enemy ships.

In 483 B.C., the Greek city-state of Athens began to build a large fleet of galleys to defend itself against invaders from Persia. As a result, Athens soon became the dominant naval power in the Mediterranean Sea. Athens defeated the Persian fleet near the island of Salamis in 480 B.C. in the first naval battle for which an extensive record exists.

In 31 B.C., the fleets of two rival Roman leaders, Mark Antony and Gaius Octavian, fought a battle off Actium in western Greece. Antony was allied with Cleopatra, the queen of Egypt, and commanded their joint fleets. Octavian's fleet won the battle. He later became Emperor Augustus of Rome. Rome reigned as the supreme naval power in the Mediterranean for the next 250 years.

Navies in the Middle Ages. From the A.D. 700's to about 1100, bold Scandinavian sailors, now known as Vikings, raided coastal and river settlements throughout western Europe. In the late 800's, the English king Alfred the Great built a large fleet of galley warships to defend his country against Viking raiders.

During the 1200's, Europeans began to build ships with large, deep hulls (main bodies). Deep-hulled ships were faster and could travel more easily on the high seas than long, low galleys. Sails rather than oars became the principal means of propulsion, though some ships still used oars when there was no wind.

Most navies of the Middle Ages followed a standard battle plan. Attacking warships sailed alongside enemy ships and hurled rocks and flaming chemicals at them. Attackers then tried to ram or board enemy ships. After boarding, the crews fought hand-to-hand using swords, hatchets, and, later, guns. Some historians believe navies first used cannons during the 1300's. But naval guns did not come into wide use until the 1500's.

Between 1405 and 1433, a Chinese fleet led by Admiral Zheng He (also spelled Cheng Ho) made a series of seven expeditions to the Indian Ocean, the Middle East, and the eastern coast of Africa. These voyages established China as the unchallenged naval power in Asia for the first half of the 1400's. China's naval supremacy ended after leaders who disapproved of contact with foreigners took control.

The beginning of modern navies. The Italian city of Venice was the major sea power in the Mediterranean during the late Middle Ages. By 1400, Venice had a fleet of about 3,000 galleys. The Ottoman Empire, based in what is now Turkey, ranked as Venice's chief naval rival. In 1571, Venice, Spain, and their allies destroyed most of the Ottoman fleet in a battle off Lepanto in Greece. This was the last major battle between oar-driven galleys.

During the 1500's, Spain and England competed for control of the Atlantic Ocean. Both countries built ships called galleons. Galleons were large, sailing ships with three masts. In the late 1500's, English galleons began harassing Spanish galleons carrying gold and silver from the Americas. In response, Spain built a fleet called the Armada. In 1588, this fleet tried to invade England. But England's galleons were smaller and easier to maneuver than Spain's, and English crews were better trained. The English defeated the Armada. England (later the United Kingdom) dominated the Atlantic for the next 300 years.

The Netherlands competed with England for control of the seas during the mid-1600's. The two countries fought several naval battles that brought important changes in military tactics at sea. By this time, fleets had become large and difficult to command. Naval commanders began issuing instructions before a battle to coordinate the movements of their ships during the fighting. Large groups of ships were divided into squadrons. Commanders used flags to signal to other ships.

The largest warships were called battleships or ships of the line because they were positioned in the main line of battle. Opposing lines of battleships sailed on parallel courses and bombarded each other with cannon fire. In the Battle of Trafalgar, off the coast of Spain in 1805, British Admiral Horatio Nelson won a major victory by breaking through and disrupting the battle line of the opposing French and Spanish navies.

Engineering advances. In 1814, American inventor Robert Fulton built the first steam-powered warship. Steamships could cruise faster than sailing ships, and they could move against or without wind. But steamships faced a new problem. They needed fuel and had to depend on land bases to supply coal for refueling. Navies had to establish fueling stations overseas.

Improvements in the range, reliability, and accuracy of shipboard guns had a tremendous impact on naval warfare. During the 1820's, inventors developed naval guns that fired explosive shells rather than solid balls. In 1833, Russian ships fired the first explosive shells used in naval battle, destroying the wooden ships of the opposing Ottoman fleet during the Crimean War. In this war, Russia fought the allied forces of the United Kingdom, France, Sardinia, and the Ottoman Empire.

In the mid-1800's, shipbuilders began covering wooden hulls with heavy iron armor plates. Inventors developed rotating turrets so that naval guns could be fired in almost any direction without turning the ship. As the range and accuracy of guns increased, ships fought at
greater distances. Crews no longer boarded enemy ships and fought hand-to-hand, as in the sailing era.

In 1862, during the American Civil War, the Union's Monitor fought the South's Merrimack (then named the Virginia) in the channel of Hampton Roads in Chesapeake Bay. Neither ship was sunk. But this battle is famous because it was the first battle between two iron- armored ships. It was also one of the first battles between ships powered entirely by steam.

In 1906, the British completed the battleship Dreadnought. The Dreadnought carried more large guns and was faster than any previous battleship. It made all other battleships out of date, and it pushed Germany and Britain into a race of modern shipbuilding.

World War I began in 1914. In the war, the Allies, who included Britain, France, Italy, Russia, and the United States, fought Germany, Austria-Hungary, and other Central Powers. The war featured two new weapons that revolutionized naval war: submarines and airplanes. Submarines armed with torpedoes sank many enemy surface ships. Airplanes, flown from airfields ashore, attacked ships, submarines, and targets on land.

Most naval battles during World War I involved only small numbers of ships. The war's largest naval battle occurred in 1916, when Britain and Germany fought the Battle of Jutland, off the coast of Denmark. Although Britain lost more ships, it forced the German fleet to withdraw and remain in port for the rest of the war.

When World War I ended in 1918, Britain, Japan, and the United States were engaged in costly shipbuilding programs. After extensive negotiations, these and other nations agreed to limit warship construction. The Treaty of Versailles, which ended military action against Germany, barred Germany from building a large navy. But Germany violated the treaty by secretly building submarines for other countries. When German dictator Adolf Hitler rose to power in the early 1930s, he ordered the construction of a large navy. Japan and the Soviet Union also began building major fleets in the 1930s.

World War II began in Europe in 1939. In that war, Germany, Italy, Japan, and smaller Axis nations fought the Allies, who included Britain, Canada, China, the Soviet Union, and the United States. Naval combat broke out in the Atlantic in 1939, when German warships began attacking British ships. Germany's goal was to cut off Britain's supply of food and war materials. Britain sank most of Germany's surface ships, forcing Germany to resort to submarine warfare. The Allies fought German submarines with airplanes, antisubmarine ships, radar, sonar, and underwater bombs called depth charges. In addition, the Allies were able to intercept and decode German radio messages, which helped them predict the movement of enemy submarines.

Naval combat began in the Pacific Ocean on Dec. 7, 1941. That day, Japanese bombers flying from six aircraft carriers made a surprise attack on the U.S. Pacific Fleet at anchor in Pearl Harbor in Hawaii. The Japanese sank or heavily damaged five U.S. battleships. But all of the U.S. Navy's aircraft carriers survived because none were then in Pearl Harbor. After the attack, aircraft carriers became the principal warship of the U.S. Navy.

The Battle of the Coral Sea, in May 1942, was the first naval battle fought entirely by carrier-based aircraft. Opposing Japanese and U.S. warships did not fire a single shot at an enemy ship. The Battle of Midway in June 1942 was the turning point for naval war in the Pacific. In this battle, the U.S. Navy sank four Japanese aircraft carriers and one cruiser. The Battle for Leyte Gulf in the Philippines, in October 1944, was one of the largest naval battles in history. This series of actions involved about 280 Japanese and U.S. warships. The battle eliminated Japan as a major naval power.

By the time Japan surrendered in 1945 and World War II ended, only the United States and Britain still had major navies. The U.S. fleet was much larger than the rest of the world's seagoing forces combined.

Navies during the Cold War. The Cold War was a period of intense rivalry that developed after World War II between Communist and non-Communist countries. During this period, many countries carried out naval building programs. Many small navies were modernized with the addition of submarines, missiles, and other advanced weapons. The Soviet Union began a drive to enlarge and modernize its fleet in the late 1940s.

After World War II, aviation experts predicted that aircraft carrying nuclear bombs would be the principal weapon in future military conflicts. As a result, the U.S. Navy concentrated on building aircraft that could fly from large carriers and carry nuclear bombs.

The Korean War (1950-1953) proved, however, that conventional naval forces were still vital to modern conflicts. In this war, the United States and other members of the United Nations aided South Korea against North Korea, which was backed by China and the Soviet Union. Airpower was not the deciding factor in ending the war, and neither side used nuclear weapons. During the war, the U.S. Navy launched carrier-based air attacks, made amphibious landings, and used shipboard guns to bombard enemy coastal targets.

In 1954, the U.S. Navy launched the world's first nuclear-powered ship, the submarine Nautilus. The first Soviet nuclear submarine was completed about five years later. The first nuclear-powered surface warships were the U.S. aircraft carrier Enterprise and the cruiser Long Beach, both completed in 1961. By the mid-1960s, both the Soviet Union and the United States had submarines with ballistic missiles carrying nuclear warheads.
The world’s navies were involved in numerous conflicts during the Cold War period. For example, in 1962, the U.S. Navy blockaded Cuba to force the Soviets to remove missiles and aircraft they had brought to the island. The U.S. Navy saw combat in the Vietnam War after the United States became heavily involved in the war in 1965. The U.S. Navy also played a major role in the Persian Gulf War in 1991. In 1982, the United Kingdom’s Royal Navy battled Argentina for control of the Falkland Islands in the South Atlantic Ocean. The Royal Navy was victorious, proving that it could fight against modern weapons at great distances from the United Kingdom.

**Navies after the Cold War.** The Cold War ended in the early 1990’s, after the Soviet Union broke apart and democratic reforms took place in Eastern Europe. Tensions eased between countries that had considered each other enemies.

Many countries, including the United Kingdom, Russia, and the United States, began reducing their navies. Older ships were cut up for scrap metal, newer ships were placed in reserve, and fewer new ships were built. Both Russia and the United States began reducing their fleets of ballistic missile submarines. However, some smaller navies, including those of France, India, and Israel, continued to build and modernize their fleets. Several of the former Soviet republics, especially Ukraine, began to build their own navies in the 1990’s. Ukraine also took over a number of small ships that had belonged to the Soviet Navy.

**Questions**

- What is the principal warship of the Russian Navy?
- What was the first battle between two iron-armed ships?
- What do navies do during times of peace?
- How were galleys and galleons powered?
- What is the main task of a small navy during wartime?
- Why did the Dreadnought make other warships out of date?
- What was the first nuclear-powered warship?
- What is a task force?

**Additional resources**

**Navy, Department of the** is one of the three military departments within the Department of Defense of the United States government. The department is responsible for having naval and marine forces trained and ready to carry out military missions ordered by the president or the secretary of defense.

The Department of the Navy has three parts: (1) the Navy Department, (2) the Operating Forces, and (3) the Shore Establishment. The Navy Department is the central executive authority of the U.S. Navy. It is composed of the headquarters of the Navy and the U.S. Marine Corps in Washington, D.C. The Operating Forces consists of the fleets, including the Fleet Marine Forces, and other major sea commands. The U.S. Coast Guard functions as part of the Operating Forces in wartime or as directed by the president. The Shore Establishment operates within the United States. It performs a variety of technical activities that support the department’s Operating Forces.

The secretary of the Navy heads the Department of the Navy, under the direction of the secretary of defense. The secretary of the Navy ranks equally with secretaries of the Army and the Air Force. The position carries general responsibility for all naval affairs. The principal civilian aides of the secretary of the Navy are an undersecretary, a deputy undersecretary, and four assistant secretaries.

The chief of naval operations, an admiral, is the Navy’s highest-ranking military officer and a member of the Joint Chiefs of Staff. The chief is the principal naval adviser to the president and the secretary of the Navy on matters of war and the principal adviser and assistant to the secretary of the Navy.

The commandant of the Marine Corps is responsible for Marine Corps activities. The commandant reports directly to the secretary of the Navy.

The United States Congress authorized the establishment of the Navy Department in 1798. As a result of the National Security Act of 1947, the Navy Department was renamed the Department of the Navy in 1949. That same year, it was placed under the direction of the Department of Defense.

Critically reviewed by the Department of Defense

See also Coast Guard, United States (National defense); Defense, Department of; Marine Corps, United States; Navy, United States.
Navy, United States, is the branch of the armed forces of the United States that acts to maintain command of the sea. In time of peace, the Navy often serves as an instrument of international relations. The very presence of naval vessels may be helpful in keeping a crisis from flaring into war. Navy ships also speed on errands of mercy, such as carrying food and medical supplies to disaster areas. Merchant vessels and passenger ships often call on the Navy for aid in emergencies.

In time of war, the Navy seeks out and destroys the enemy on, under, or above the sea. It can also strike the enemy ashore. In fact, if attacked, the Navy can return the blow almost anywhere on earth from its warships and aircraft. Powerful naval amphibious forces can support troop landings against heavy enemy resistance. Nuclear-powered submarines can carry missiles and travel around the world underwater. Any enemy that might attack the United States must expect counterblows from these submarines, whose exact locations at sea cannot be pinpointed.

To perform its functions efficiently, the Navy has many types of ships, including aircraft carriers, battleships, cruisers, frigates, destroyers, submarines, and amphibious type ships. These fighting ships depend on the services of ammunition ships, minesweepers, oilers, repair ships, supply ships, and tugs. Both fighting ships and service ships rely on a shore organization, including naval bases, shipyards, docks, naval air stations, and training stations, for supplies, repairs, training, and other services.

Many people choose the Navy as a career because of their love of adventure and the sea. They may have an opportunity to visit many parts of the world.

The history of the U.S. Navy is a colorful story of daring deeds and famous ships at sea. It is the story of growth from a few sailing ships in Revolutionary War
days to the greatest fleet ever to sail the seas. It recounts
the changes from sails and cannon to nuclear power
and guided missiles. It blazes with the achievements of
such historic ships as the Bonhomme Richard, Constitu-
tion, Monitor, Olympia, Enterprise, and Nautilus.

Naval history tells of John Paul Jones, whose battle
cry, "I have not yet begun to fight," established the
Navy's fighting traditions. It includes the achievements of
James Lawrence, who rallied his men with the historic
words: "Don't give up the ship!" It reflects the deeds of
David G. Farragut, the Navy's first admiral, who report-
edly bellowed "Damn the torpedoes! Full speed ahead!"
as his forces charged into Mobile Bay. It includes lead-
ers such as Chester W. Nimitz, who directed the Pacific
Fleet in its sweep from Pearl Harbor to Tokyo Bay, and
Hyman G. Rickover, the father of the nuclear Navy. It
shines with the names of famous ships, such as the Na-
tilus, the world's first nuclear-powered warship.

The Navy operates under the Department of the Navy.
The Navy has an active strength of about 320,000 men
and 52,000 women. Active naval reserve forces total
about 180,000. The department also maintains a Marine
Corps of about 170,000 and employs more than 125,000
U.S. citizens worldwide. In wartime, or by decision of
the president, the Coast Guard also operates under the
Department of the Navy.

The Navy seal was adopted in 1957. "Anchors Aweigh"
is the Navy's famous marching song. Blue and gold are
the official colors of the Navy.

Life in the Navy

Training a sailor. The enlisted ranks consist of three
grades of seaman and six grades of petty officer, from
seaman recruit to master chief petty officer. Navy re-
cruits first learn discipline and seamanship at a naval
training center called a boot camp. They are called
"boots" because, in early days, recruits wore leggings
that looked like boots. Then they may attend a trade
school, such as those for enginemen, cooks, and electrici-
s. Or they may be assigned directly to a ship where
they learn their duties and practice their trades. Sailors
take competitive examinations for advancement through
the ratings ranks. Some may be qualified to attend ad-
vanced schools.

Enlisted women receive basic training at the naval
training center in Great Lakes, Illinois. About half of
them are assigned to advanced training schools, and the
rest receive on-the-job training at naval bases. Qualified
enlisted men and women can take examinations for ad-
mission to the U.S. Naval Academy at Annapolis, Mary-
land, or to other officer training programs.

Training an officer. Navy officers are trained at the
U.S. Naval Academy or in the following naval programs:
(1) the Naval Reserve Officers Training Corps (NROTC)
for college and university students; (2) officer-candidate
training for enlisted personnel and college graduates; (3)
aviation-officer candidate programs for men and
women with college degrees; and (4) programs to ap-
point warrant officers and limited-duty officers from the
enlisted ranks.

Doctors, dentists, and ministers may be commis-
sioned with little military training. Officer candidates
train at the Naval Officer Candidate School, Newport,
Rhode Island. The Navy admits women to all programs.

Naval officers are assigned to one of four divisions: (1)
line, (2) staff, (3) limited duty, or (4) warrant. Unrestricted
line officers command at sea or manage shore activities.
Restricted line officers have highly specialized jobs,
such as engineering or public affairs. Staff officers in-
clude doctors, dentists, nurses, supply officers, lawyers,
and chaplains. Limited-duty or warrant officers are usu-
ally appointed from the enlisted ranks as administrative
or technical specialists.

During officer training, officer candidates may apply
for surface, submarine, or aviation duty. After about four
years of active duty, they become eligible for many tech-
nical postgraduate programs. Senior-ranking officers
may take command and strategy courses at the Naval
War College in Newport, Rhode Island, or at one of the
joint service colleges, such as the National War College
in Washington, D.C.

A typical day. Life at sea for bluejackets (sailors)
varies with the type of ship they are on. Naval ships
range from tugboats with a crew of five to giant aircraft
 carriers with a crew of thousands. Cargo ships spend
long periods at sea. Repair ships usually stay in port, but
they are sometimes sent overseas to support operating
forces. A sailor on a submarine gets to know every
member of its crew. But on an aircraft carrier, each crew
member does a specialized job and may never even see
many areas of the ship.

In peacetime aboard a naval ship, a typical day begins
about 6 a.m. Meals are generally served at 7 a.m., noon,
and 5 p.m. These hours may vary to meet operating re-
quirements. The crew musters (assembles) at 8 a.m., after
breakfast. Practically every crew member on a ship
stands watch, or is at a post of duty, during four-hour
periods. Each member has a battle station and a post for
emergencies.

Inspection in the ranks may be held ashore or aboard a ship.
These Navy enlisted men are undergoing inspection with weap-
s. The officer marches in front.
The Navy tries to make life aboard ship as comfortable and pleasant as possible for sailors who may have to live in limited space for weeks or months at a time without seeing land. Some ships have a library for the crew, and many have recreation rooms and hobby shops. Most ships have on-board television and radio stations. Tailor and shoe-repair shops, laundries, and stores located on the ship provide for the crew’s everyday needs. On large ships, doctors and dentists care for the sailors’ health. When a ship is in port, crew members who are not on duty may be granted liberty (time off ashore).

**Careers in the Navy.** A sailor has a chance to see much of the world. A first enlistment may prepare a person for a civilian job or a naval career. Applicants must be U.S. citizens between the ages of 17 and 34, and must meet the Navy’s physical standards. A man or woman may enlist for four to six years.

Qualified enlisted personnel may advance to chief petty officer in 12 to 14 years. They receive a pay increase with each promotion, and extra pay according to length of service. The Navy also pays money for quarters (housing) and subsistence (food). It gives additional pay for hazardous duty, such as submarine and aviation duty, and for sea duty and duty in some foreign countries. All Navy personnel are eligible for 30 days’ leave (vacation) a year. They are entitled to free medical and dental care, and free hospital and medical care is available to their families. Men and women in the Navy may retire with pay after 20 years’ service.

**Ships and weapons of the Navy**

**Combat ships** of the U.S. Navy include warships, amphibious warfare ships, and mine warfare ships. Smaller vessels, called light combatant craft, patrol coastlines, land troops, and operate on rivers and other shallow waterways. This section discusses the U.S. Navy’s warships. For information on amphibious warfare ships and mine warfare ships, see Amphibious ship; Mine warfare.

The U.S. Navy’s aircraft carriers are its largest warships. Special helicopter and troop carriers take part in helicopter amphibious assaults. Battleships, the largest nonaviation ships, bombard enemy shore positions and attack enemy ships. Guided missile cruisers are used mainly to escort aircraft carriers. Destroyers defend amphibious ships and large warships. Some destroyers carry helicopters that can attack submarines. Frigates escort other warships and amphibious ships and are also used for patrol duty. Submarines operate against surface ships, other submarines, and shore positions. Command ships carry communications equipment and serve as command headquarters.

**Auxiliary ships** provide maintenance, fuel, supplies, towing, and other services to warships. There are four main kinds of auxiliary ships: (1) underway replenishment ships, (2) fleet support ships, (3) sealift ships, and (4) experimental, research, and surveying ships. Service craft generally are smaller vessels that provide services similar to those of auxiliary ships.

Underway replenishment (UNREP) ships provide fuel, ammunition, food, spare parts, and other materials to warships at sea. UNREP ships transfer cargo to moving ships using lines rigged between the ships. Fleet support ships provide maintenance and towing services to warships. Destroyer tenders, submarine tenders, and repair ships have machine shops that can repair the engines, weapons, and electrical systems of warships. Oceangoing tugs provide towing services to warships.

Sealift ships carry cargo from port to port but cannot land their cargo on beaches. Unlike UNREP ships, they cannot transfer cargo to moving ships.

Experimental, research, and surveying ships support warship development and operations. Experimental ships test hull designs, weapons, and other equipment. Research ships are used in studying the ocean and the ocean floor. Surveying ships map the ocean floor and coastlines.

**Naval aviation** enhances the defense of the fleet, joins amphibious attacks, and conducts strikes on ships and shore targets. Navy pilots fly attack, fighter, and special mission planes and helicopters from carriers. They also fly shore-based patrol aircraft. Carrier-based aircraft are built to withstand the great stress of take-off and landing. Their wings can be folded to reduce the amount of storage space needed.

Navy attack aircraft include the light attack A-7 Corsair II and the medium attack A-6 Intruder. Fighters are the F-14 Tomcat and F/A-18 Hornet. Navy aircraft can carry a variety of ordnance (weapons), including guided missiles and nuclear warheads.

Special mission aircraft that operate from carriers include the S-3 Viking, which has electronic and radio devices to find and track submarines. The EA-6B Prowler is an electronic warfare plane used to interfere with enemy electronic equipment. The F-3 Orion is a land-based antisubmarine warfare plane. The SH-60 Seahawk is a ship-based antisubmarine helicopter.

Navy aircraft are classified by letters and numbers. For example, the F-14D is the fourteenth fighter (F) in the Department of Defense system. The letter D indicates that it is the fourth model of the F-14. Other letters are A: attack; E: special electronic installation; C: cargo/transport; H: helicopter; K: tanker; O: observation; P: patrol; S: antisubmarine; T: trainer; U: utility; V: vertical or short take-off and landing; and X: research.

**Ordnance** includes bombs, guns, mines, missiles, and torpedoes. Battleships carry the Navy’s largest guns. These are 16-inch guns that can hurl shells more than 20 miles (32 kilometers). Cruisers and destroyers carry 5-inch guns that can shell targets more than 10 miles (16 kilometers) away. Surface warships also carry 3-inch rapid-fire guns for defense against enemy aircraft.

Navy mines may be fixed, moored, or mobile. Rockets such as ASROC and SUBROC combat submarines. The Navy has air-launched, surface-launched, and subsurface-launched torpedoes. They can be used against surface ships or submarines.

**Missiles.** Surface-to-air missiles include the Standard II, Tartar, and Terrier missiles, with ranges from 10 to 25 miles (16 to 40 kilometers) or more. Air-to-air missiles include Phoenix, Sidewinder, and Sparrow. Such air-to-surface missiles as Harpoon and HARM are used to support ground troops or hit targets at sea. The Poseidon can be launched underwater to blast targets up to 2,500 miles (4,020 kilometers) away. Trident missiles have a range of about 4,000 miles (6,400 kilometers). Underwa-
ter-to-air-to-underwater missiles are launched from submarines. See Guided missile.

Organization of the Navy

The U.S. Navy operates under the Department of the Navy in the Department of Defense. The Department of the Navy consists of the (1) Navy Department, (2) Operating Forces, and (3) Shore Establishment. The secretary of the navy, a civilian, heads the Department of the Navy under the direction of the secretary of defense. The secretary of the navy is responsible for the policies and control of the Department of the Navy.

The Navy Department, located in Washington, D.C., is the central executive authority of the Department of the Navy. The Navy Department establishes policy, directs, and controls the Operating Forces and Shore Establishment. It includes the offices of the secretary of the navy, chief of naval operations, chief of naval personnel, chief of naval research, and commandant of the marine corps.

The Operating Forces perform naval operations to carry out U.S. policies and advance U.S. interests. The main parts of the Operating Forces are the U.S. Atlantic Fleet, the U.S. Pacific Fleet, and their fleet marine forces (expeditionary troops), who are members of the Marine Corps. The U.S. Atlantic Fleet, headquartered at Norfolk, Virginia, provides forces for the Second Fleet in the western Atlantic; the Sixth Fleet in the Mediterranean; and the Middle East Force in the Indian Ocean area, including the Persian Gulf. The Pacific Fleet, headquartered at Pearl Harbor, Hawaii, is made up of the Third Fleet in the eastern Pacific and mid-Pacific, and the Seventh Fleet in the western Pacific.

Also in the Operating Forces are the Naval Reserve; the Mine Warfare Command; and the Operational Test and Evaluation Force, which tests and evaluates weapons systems, ships, aircraft, and other equipment. Another part of the Operating Forces, the Military Sealift Command, consists of noncombatant ships and commercial vessels manned by civilian crews. This command transports bulk cargo for the Department of Defense and its divisions. It also provides naval fleet auxiliary forces to support U.S. Navy operations worldwide and operates ships for projects of other U.S. agencies. The command is partly responsible for restocking ships at sea with fuel, food, and other supplies.

The Shore Establishment operates naval bases and other installations that support the Operating Forces. A naval base may include a shipyard, a naval station, or a naval air station. Other installations in the Shore Establishment are hospitals, research laboratories, naval training centers, technical schools, supply depots, and communications stations. In addition, the Shore Establishment assigns officers as naval attaches to the diplomatic staffs of ambassadors or ministers to foreign countries. Naval attaches openly collect information about the military capabilities of other countries.

Regulars and reserves. The Regular Navy, or Active Navy, is the permanent professional naval force. It consists of men and women who join the Navy as a career.

The Naval Reserve consists of the Ready Reserve, the Standby Reserve, and the Retired Reserve. The Naval Reserve provides trained units and qualified individuals for active duty in time of war or national emergency.

The Ready Reserve is the core of the Naval Reserve. Its members are ready to be immediately mobilized. Ready reservists may be on active duty or in inactive duty status. Selected reservists are ready reservists who train for two days a month at naval reserve centers or naval air stations and perform two weeks of active duty a year.

Standby Reserve and Retired Reserve members are subject to recall in a war or national emergency. But they do not get the amount or regularity of training that selected reservists do, and so they would be mobilized only after selected reservists were called up.

Women in the Navy do not form a separate organization or unit, except for those in the Navy Nurse Corps. Women other than nurses serve as enlisted or commissioned personnel in the Regular Navy or in the Naval Reserve. Nurses serve as commissioned officers in the Naval Reserve and may transfer to the Regular Navy.

Navy women are trained, assigned, paid, and administered under essentially the same policies as are Navy men. They have the same service rights and benefits. Women are not assigned to combat units, but they may serve at overseas bases and on noncombatant ships.

Navy nurses may serve in combat zones.

Women first served in the Navy during World War I. They performed yeoman (clerical and secretarial) duties to release enlisted men for active duty at sea. In 1942, during World War II, Congress authorized the establishment of the Women's Reserve of the United States Naval Reserve. Navy women became known as WAVES; the abbreviation for the full name of this organization, Women Accepted for Volunteer Emergency Service. Mildred H. McAfee, a distinguished educator, was the first director of the WAVES (see McAfee, Mildred H.).

In 1948, women officially became a permanent part of the Regular Navy and the Naval Reserve. The term WAVES is no longer an official title. Navy women are referred to as women officers and enlisted men.

The Marine Corps is a separate military service within the Department of the Navy. Its commandant is responsible directly to the secretary of the navy. The corps assigns fleet marine forces to the Atlantic and Pacific fleets. The Marines have the primary jobs of amphibious warfare and land operations performed in connection with naval campaigns. They also provide security forces that guard naval stations and ships and United States embassies in other countries. See Marine Corps, United States.

The Coast Guard operates under the Department of the Navy in wartime or by decision of the president. The Coast Guard provides air-sea rescue services, carries out antisubmarine patrols, and controls and guards shipping in U.S. ports. It also helps to prevent waterfront disasters, to enforce U.S. laws at sea, and to ensure safety at sea. See Coast Guard, United States.

History

The earliest colonial warships were privately owned vessels called privateers. These vessels usually operated on independent missions (see Privateer).

The Continental Congress established the Continental Navy in 1775. The Congress set up a Naval Committee and later a Marine Committee to administer naval affairs and to build and equip warships. Several merchant
Uniforms of the U.S. Navy include the summer white uniform, far left, and three types of service blue uniforms. All the uniforms shown above except the jumper, far right, are worn by officers and enlisted personnel. The jumper is worn by seamen through petty officer first class.

**Officers’ rank insignia**

- **Line officers**
  - Sleeve mark
  - Shoulder mark
  - Khaki and winter blue shirt collar mark
  - Fleet Admiral
  - Admiral
  - Vice Admiral
  - Rear Admiral (Upper Half)
  - Rear Admiral (Lower Half)

- **Warrant officers**
  - W.4
  - W.3
  - W.2
  - W.1

**Enlisted personnel grade insignia**

- **Rating badges (Petty officers)**
  - Master Chief Petty Officer of the Navy
  - Fleet/Command Master Chief Petty Officer
  - Master Chief
  - Senior Chief
  - Chief
  - 1st Class
  - 2nd Class
  - 3rd Class

- **Group-rate marks (Lower pay grades)**
  - Seaman
  - Constructionman
  - Fireman
  - Airman
  - Seaman Apprentice
  - Constructionman Apprentice
  - Fireman Apprentice
  - Airman Apprentice

- **Service stripes**
  Service stripes are worn near the bottom of the sleeve. Each stripe stands for four years of service.
Some officers' devices

The emblems are embroidered on the sleeves of blue uniforms to indicate specialties. They also are worn on shoulder boards and on the collars of khaki and winter blue shirts of staff officers.

Officer (Staff corps)

- Medical Corps
- Supply Corps
- (Christian) Chaplain Corps
- (Jewish) Civil Engineer
- Medical Service Corps
- Judge Advocate General Corps
- Leader, U.S. Navy or Naval Academy Band
- Dental Corps
- Nurse Corps

Warrant officer (Line)

- Boatswain
- Cryptologic Technician
- Security Technician
- Intelligence Technician
- Engineering Technician/Nuclear Power Technician
- Ship's Clerk
- Ordnance Technician
- Line Officer

Some breast insignia

The emblems are worn by officers and enlisted personnel on the left breast of their uniform to indicate specialization. Emblems marked with an asterisk may be worn only by an officer.

- Astronaut*
- Naval Aviator
- Surface Warfare*
- Aircrew
- Flight Surgeon*
- Basic Parachutist
- SSBN Deterrent Patrol
- Submarine
- Submarine Medical*
- Submarine Engineering Duty*
- Submarine Combat Patrol
- Special Warfare

Some specialty marks for general ratings

Specialty marks show the duties of enlisted personnel. Petty officers wear the marks on the rating badge, between the eagle's talons and the upper chevrons. Sailors in the lower pay grades wear them above the group-rate marks.

- Aviation Electronics Technician
- Aviation Machinist's Mate
- Aviation Ordnanceman
- Aerographer's Mate
- Air Traffic Control Technician
- Aviation Boatswain's Mate
- Aviation Electrician's Mate
- Aircrew Survival Equipmentman
- Photographer's Mate
- Machinist's Mate
- Engineman
- Boiler Technician
- Aviation Anti-submarine Warfare Technician
- Electrician's Mate
- Patternmaker
- Molder
- Interior Communications Electrician
- Builder
- Construction Electrician
- Construction Mechanic
- Equipment Operator
- Torpedoman's Mate
- Gunner's Mate
- Fire Control Technician
- Mineman
- Electronics Technician
- Missile Technician
- Boatswain's Mate
- Quartermaster
- Operations Specialist
- Sonar Technician
- Musician
- Data Systems Technician
- Journalist
- Instrumentman
- Radioman
- Cryptologic Technician
- Personnelman
- Data Processing Technician
- Storekeeper
- Disbursing Clerk
- Hospital Corpsman
- Signalman
- Yeoman
- Dental Technician
ships were converted into combat vessels. In 1776, Esek Hopkins, the Navy's first commodore and its first commander in chief, raided Nassau in the Bahama Islands with a fleet of six ships. During the Revolutionary War, about 60 vessels served in the Continental Navy. Captain John Paul Jones's badly damaged Bonhomme Richard forced the British vessel Serapis to surrender in one of the war's most exciting battles. Jones uttered the Navy's famous watchword: "I have not yet begun to fight!" See Revolutionary War in America.

The Navy ceased operations after the war. In 1785, the last warship was sold. But the need for a fleet soon arose again. Barbary corsairs (sea raiders) off North Africa preyed on American merchant ships and killed or captured American sailors. In 1794, Congress voted to build several frigates (at that time, fast, three-masted warships) to fight the corsairs. This force operated under the secretary of war. The launching of the United States in 1797 marked the rebirth of the U.S. Navy.

Undeclared war with France. In the summer of 1796, the United States and France had reached a state of undeclared war. France and Britain were at war with each other at this time. The French treated U.S. merchant sailors like British subjects and, by 1798, had seized over 300 U.S. merchant ships. That year, Congress created a Navy Department under a secretary of the Navy. The 44-gun frigates Constitution and United States and the 36-gun Constellation formed the basis of a new fleet that had grown to about 50 ships by 1801. Many battles raged between U.S. and French ships. The undeclared war with the United States ended after Napoleon Bonaparte seized power in France in 1799.

The War of 1812 (1812-1815). Britain declared a blockade of France when war broke out in 1803. It seized American ships that violated the blockade, and imprisoned their seamen. The U.S. Navy had only about 16 warships when the War of 1812 began.

In early victories, the Constitution captured and destroyed the British ships Guerrière and Java, and the United States captured the Macedonian. The British Shannon captured the American Chesapeake. Captain James Lawrence of the Chesapeake issued as his dying command: "Don’t give up the ship!" The British clamped a tight blockade on American ports, but American privateers continued to operate. They captured more than 1,300 enemy vessels and damaged British overseas trade. American ships won decisive victories on Lake Erie and Lake Champlain. See War of 1812.

In the Mexican War (1846-1848), the Navy conducted amphibious operations and blockaded ports along Mexico’s Gulf and Pacific coasts.

The Civil War (1861-1865) found the Union Navy with only 42 ships. Within a month after the war began on April 12, 1861, the Navy had blockaded the Southern States from Virginia to the Rio Grande to keep them from exporting cotton and importing supplies. The Confederacy countered with naval commerce raiders and blockade runners, which were operated independently. In March 1862, the first battle between ironclad ships occurred at Hampton Roads, Virginia. The clash between the Confederate Virginia (Merrimack) and the Union Monitor ended in a draw but introduced a new kind of naval warfare (see Monitor and Merrimack).

Navy gunboats helped Union forces control the Tennessee, Cumberland, and Mississippi rivers, which led to the siege and capture of Vicksburg, Mississippi, in 1863. See Civil War (Siege of Vicksburg).

In August 1864, Rear Admiral David G. Farragut ran his fleet past defending forts at Mobile Bay, Alabama, and forced a Confederate fleet in the harbor to surrender. As Farragut entered the bay, he reportedly shouted, "Damn the torpedoes! Full speed ahead!"

The Navy played an important role during the Civil War. It was essential to the success of the land armies, and showed the powerful effect of control of the seas. The Union Navy came out of the war as the largest and most powerful naval force in the world. It had more than 670 ships and 57,000 men. See Civil War.

The Spanish-American War (1898) saw two major naval battles. On May 1, Commodore George Dewey’s squadron steamed through the entrance to Manila Bay in the Philippines. As his flagship Olympia approached the Spanish fleet off Cavite, he gave the historic command: "You may fire when you are ready, Gridley." The battle ended with the 10–ship enemy fleet destroyed or burning. On July 3, Commodore Winfield S. Schley’s warships defeated a Spanish fleet outside Santiago harbor in Cuba. See Maine (ship); Spanish-American War.

"The Great White Fleet." A force of 16 battleships and 4 destroyers of the Atlantic Fleet began a 14-month world cruise in 1907. It was called "the Great White Fleet," because the ships had been painted white. The 46,000-mile (74,000-kilometer) cruise proved that the Navy could easily shift from the Atlantic to the Pacific.

The Navy took two other major steps in the early 1900s. In 1913, it established the office of chief of naval operations. Admiral William S. Benson was the first to fill this position. Naval aviation was born during this same period. In 1911, the Navy purchased its first airplane. Shortly before, on Nov. 14, 1910, Eugene Ely had made the first shipboard take-off from a warship, the cruiser Birmingham. By 1914, the Navy had established its first permanent naval air station at Pensacola, Florida, and in 1922, it commissioned its first aircraft carrier, the Langley.

World War I (1914-1918) began for U.S. combat forces on May 4, 1917, when a destroyer division docked in Ireland for duty with Britain’s Royal Navy. In April, Rear Admiral William S. Sims had arrived in London to command U.S. Naval Forces in European waters. The British predicted an Allied defeat in six months unless the German submarine attacks could be stopped. The Allied navies began convoys and assigned destroyers and submarine chasers to the Atlantic.

The Navy developed new types of mines and laid a mine barrage (field) in the North Sea. It planted about 56,000 mines in the largest mining operation in history. During the war, the Navy transported more than 2 million American soldiers across the Atlantic Ocean without a single loss of life. Naval aviation expanded rapidly with the establishment of bases in Europe. Navy pilots flew reconnaissance (observation), antisubmarine, and bombing missions. The Navy also mounted five 14-inch (36-centimeter) guns on railroad cars for strategic shelling of German railways and supply depots in 1918. See World War I.

After World War I, the Navy entered a period of decline. It scrapped, sank, or demilitarized about 2 million
long or metric tons of ships, including 31 major warships, according to a treaty signed at the Washington Conference of 1921 and 1922 (see Arms control). By the 1930's, the United States had again started building ships. It planned a two-ocean Navy.

**World War II (1939-1945).** The Japanese attack against the Pacific Fleet at Pearl Harbor, Hawaii, on Dec. 7, 1941, brought the United States into World War II. Nearly four years later, the war ended with surrender ceremonies held aboard the battleship *Missouri* in Tokyo Bay, Japan.

The Navy had begun defense activities as early as 1939. The destroyer *Reuben James* became the Navy’s first casualty of the undeclared war in the Atlantic when it was sunk by a German submarine on Oct. 31, 1941.

The Navy recovered quickly from its losses at Pearl Harbor. It salvaged and repaired many of the damaged or sunken ships. Admiral Ernest J. King became commander in chief of the United States Fleet. In addition, he later served as chief of naval operations. Admiral Chester W. Nimitz took command of the Pacific Fleet, and Admiral Royal E. Ingersoll commanded the Atlantic Fleet. By June 1942, the Navy's decisive victory in the Battle of Midway marked the end of Japanese expansion in World War II. When the war ended, the Navy had the most powerful fleet ever. It had 3,400,000 men and women and 2,500 ships, including 24 battleships, 35 aircraft carriers, 77 escort carriers, 92 cruisers, 501 destroyers, 406 destroyer escorts, and 262 submarines. See World War II.

**The Korean War (1950-1953)** involved naval forces almost immediately after the conflict began. Aircraft carriers and troop transports played vital roles in holding the Pusan perimeter during the first three months of the war. On Sept. 15, 1950, an amphibious landing at Inchon helped reverse the course of the war. A feature of the ground battles was the success of naval and marine close air support, with aircraft and infantry operations closely coordinated. See Korean War.

**The Persian Gulf War (1991).** In August 1990, the United States sent naval forces to the Persian Gulf after Iraq invaded Kuwait. In January 1991, war broke out between Iraq and a multinational force led by the United States. United States Navy planes conducted strikes against Iraqi troops and military installations. The battleships *Wisconsin* and *Missouri* bombarded Iraqi targets ashore. During the brief ground war, fought in late February, the threat of an amphibious landing of U.S. Marines in Kuwait kept as many as six Iraqi divisions pinned down. See Persian Gulf War.

**The nuclear age Navy.** In 1948, the U.S. Navy and the Atomic Energy Commission established a joint program to develop nuclear-powered submarines. Unlike conventional submarines, which burn fuel oil, nuclear submarines do not require air for combustion. They can thus travel long distances underwater. In 1954, the Navy commissioned the world’s first nuclear-powered submarine, the *Nautilus*. In 1981, the Navy commissioned the *Ohio*, the first nuclear submarine armed with powerful Trident missiles. Today, the Navy has about 95 nuclear submarines, all of which carry missiles.

The U.S. Navy also developed nuclear-powered surface ships, which can steam at high speed for long distances without refueling. The Navy’s first nuclear surface ships, the cruiser *Long Beach* and the aircraft carrier *Enterprise*, were completed in 1961. Today, more than 40 percent of the Navy’s fighting vessels are nuclear powered.

In 1975, the lead ship of the *Tarawa (LHA-1)* class of amphibious warfare ships was commissioned. This class of vessel transports landing craft and provides a flight

---

**Important dates in Navy history**

1779 John Paul Jones's *Bonhomme Richard* outfought the *Serapis* and gave the Navy its famous watchword: "I have not yet begun to fight."

1794 The United States Navy was formally established in a law providing for ship construction.

1812 The *Constitution* under Isaac Hull overwhelmed the British ship *Guerrrrière* in the War of 1812.

1813 James Lawrence and the *Chesapeake* fell before the cannons of British warship *Shannon*. The dying Lawrence commanded: "Don't give up the ship!"

1862 The first battle between ironclad warships was fought between the *Monitor* and the *Merrimack* (Virginia).

1864 A Union fleet stormed into Mobile Bay as its commander, David Farragut, reportedly bellowed: "Damn the torpedoes! Full speed ahead!"

1898 The United States fleet under George Dewey crushed the Spanish fleet in Manila Bay.

1942 The Pacific Fleet repulsed a Japanese fleet that threatened Midway Island and Hawaii.

1944 In the biggest naval battle in history, the Pacific Fleet destroyed Japanese sea power off Leyte Gulf.

1958 The world's first nuclear submarine, *Nautilus*, cruised beneath the North Pole, the first ship to reach it.

1964 A nuclear-powered task force cruised around the world.

1972 Alene B. Duerk became the first woman in the Navy to be promoted to the rank of rear admiral.

1976 Samuel Lee Gravely became the Navy's first black vice admiral.

---

**Names of naval ships**

Since the 1970's, the United States Navy has generally named various types of ships after people, places, or things, as follows:

**Aircraft carriers**—Public officials (Theodore Roosevelt, Abraham Lincoln, Dwight D. Eisenhower, Carl Vinson).

**Amphibious assault ships**—Famous Navy ships (Wasp).

**Battleships**—States (New Jersey).

**Cruisers**—Battles (*Ticonderoga, Yorktown*) or states (*California, Virginia*).

**Destroyers**—Officers and enlisted personnel of the Navy and Marine Corps, Navy secretaries, members of Congress, or inventors who influenced naval matters (*Kidd, Coontz, Adams, David R. Ray, Fife*).

**Frigates**—Deceased Navy, Marine Corps, or Coast Guard personnel (*Lewis B. Puller, Jack Williams*).

**Minersweepers**—Descriptive qualities (*Avenger*) or birds (*Cardinal*).

**Submarines**—Trident ballistic missile submarines are named for states (*Ohio, Alaska*). Attack submarines are named for cities (*Los Angeles, Chicago*).
Historic ships of the United States Navy

The _Bonhomme Richard_, commanded by John Paul Jones, outfought the British ship _Serapis_ in the Revolutionary War.

The _Constitution_, under the command of Isaac Hull, destroyed the British frigate _Guerrière_ during the War of 1812.

A Civil War clash in 1862 between the Union _Monitor_ and the Confederate _Merrimack_, also called the _Virginia_, was the world's first battle between ironclad ships. The flat-topped _Monitor_ was built of iron, but the _Merrimack_ was a wooden frigate covered with iron plates.

The _Olympia_, under the command of George Dewey, helped rout the Spanish fleet in the Battle of Manila Bay in 1898.

Transports carried more than 2 million American troops to fight in France during World War I.

The _Enterprise_ and other fast aircraft carriers formed the backbone of the U.S. Navy during World War II.

The _Missouri_ was the scene of the surrender ceremonies with Japan that marked the end of World War II.

The _Nautilus_ was the first nuclear submarine. It made the first undersea cruise beneath the North Pole in 1958.

An _Ohio_ class submarine, which carries Trident missiles, is the largest and most powerful submarine in the U.S. Navy.
deck for helicopters and vertical/short take-off and landing (V/STOL) aircraft. In 1989, the Navy launched the lead ship of the Arleigh Burke (DDG-51) class of destroyers with weapons for fighting surface ships, submarines, and aircraft. In 1997, the Seawolf (SSN-21) class of nuclear-powered attack submarines was put in service. Critically reviewed by the United States Navy

**Additional resources**

**Navy Jack** is a flag of the United States Navy. It has 50 white stars on a blue background. The Navy Jack looks like the blue and white corner portion of the United States flag.

Whitney Smith

See also Flag (picture: The shapes of flags).

**Nazarybayev**, [NAZHY by EVH, Nursultan](http://www.worldbookonline.com/article/wb-ES-AAD928716), NUR Suhl TAHN (1940- ), was elected president of Kazakhstan in 1991. Kazakhstan, formerly part of the Soviet Union, declared its independence shortly after the election.

As president, Nazarybayev has worked to replace Kazakhstan’s traditional government-run economy with one that promotes free enterprise. To do this, his government has sold some state-owned factories and farms to private citizens. He has opposed all efforts to split Kazakhstan into two countries, one inhabited chiefly by its Kazakh people and the other by its Russian people. Nazarybayev has been criticized for increasing his power as president and for restricting freedom of the press.

Nazarybayev was born near Aimbai. He graduated from the Technical University at Qaraghandy Metalurgical Combine in 1967. From 1984 to 1989, Nazarybayev was prime minister of the Soviet republic of Kazakhstan. He was first secretary of the Kazakh Communist Party from 1989 to 1991. In 1990, the Supreme Soviet (legislature) elected him president of Kazakhstan. He quit the Communist Party in 1991 as the Soviet Union fell apart.

Nazareth, [NAZHY uhr iuht](http://www.worldbookonline.com/article/wb-ES-AAD928716), NAZH (pop. 52,200), is a town in northern Israel. For the location of Nazareth, see Israel (political map). It was the home of Jesus Christ during His early youth. The town was in the Roman province of Galilee (see Galilee).

The Old Testament does not mention Nazareth. Nathanael in the New Testament expressed the attitude of the times about the village when he said, “Can there any good thing come out of Nazareth?” (John 1:46).

Nazareth remained insignificant for many years after the time of Christ. But pilgrims visited the town about A.D. 600, and a large basilica was built. The Arabs captured the city in the 600s. The Crusaders built several churches there, but the Ottomans, who were Muslims, forced Christians to leave in 1517.

A new town of Nazareth stands on the site of the old town. The population of Nazareth today is far more than its population in Biblical times. The Latin Church of the Annunciation, completed in 1730, now rises where some people think the home of Mary, the mother of Jesus, stood. Since the 1700s, several religious denominations have constructed churches and monasteries in Nazareth. An ancient well, called Mary’s Well, still flows, and people still take water from it.

---

**Bernard Reich**
Nazca lines include giant figures etched into the earth's surface by the Nazca people of ancient Peru. One of the figures, a bird-like drawing, is shown in the aerial photograph above. This figure measures about 450 feet (135 meters) from head to tail.

**Nazca**, NAHS kuh, was an American Indian culture that thrived in the coastal desert of what is now southern Peru from as early as 100 B.C. to A.D. 800. The Nazca people are known for the huge etchings they made in the surface of the desert and for their colorful pottery. The name of the culture is also spelled *Nasca*.

The desert etchings, called the *Nazca lines*, include sets of parallel lines, and the outlines of animals and geometric shapes. Some of the lines are several miles long, and some of the animal figures measure more than 400 feet (120 meters) in length. The Nazca made the markings by removing dark surface rocks to expose light-colored sand underneath. The Nazca may have used the markings to follow the positions of stars in the night sky and thus to keep track of the seasons.

Nazca pottery includes bowls and other vessels and such musical instruments as pipes, drums, and rattles. The Nazca decorated much of the pottery with plant and animal designs. Some vessels are shaped like animals or people. The Nazca also wove cotton and wool textiles.

The Nazca lived in villages. They built their homes of canes tied together and covered with mud. Larger structures were made of adobe. The Nazca used irrigation to grow corn and other crops. About A.D. 800, the Nazca culture became mixed with the Huari Indian culture, possibly after an invasion of the Nazca region.

Alexandra M. Ulana Klymyshyn

**Nazism**, NAHT shz uhm or NAT shz uhm, was a political movement—and later a form of government—that developed in Germany during the 1920s. The Nazis, led by the dictator Adolf Hitler, controlled Germany from 1933 to 1945. *Nazism* also describes any governmental system or political beliefs resembling those of Hitler's Germany. The word is also spelled *Naziism*.

Nazism was a fascist movement—that is, it tightly restricted personal freedom but permitted private ownership of property. The Nazis called for aggressive nationalism, militarism, and the expansion of Germany's borders. They glorified the Germans and other northern European peoples, whom they called *Aryans*. They claimed that Jews, Slavs, and other minority groups were inferior. Nazism opposed democracy, Communism, socialism, feminism, and other political systems and movements that claimed to favor equality. It promised to build a harmonious, orderly, and prosperous society for Germans. Instead, it brought terrorism, war, and mass murder.

**The birth of Nazism.** Germany experienced political and economic crises after its defeat in World War I (1914-1918). A democratic government had replaced the monarchy that ruled the country. But the nation suffered from severe inflation and unemployment after the war ended. Many Germans lacked faith in the new government and began to turn to political groups that called for extreme changes. One of these organizations was the German Workers' Party, a small discussion group in Munich. Hitler joined this group in 1919 and quickly gained control. He changed its name to the National Socialist German Workers' Party in 1920. *Nazi* stands for the first word in the German name of the party.

Nazism responded to deep problems in German history. Germany had not become a united nation until 1871, and many Germans felt that Germany was inferior to other countries. This feeling of inferiority encouraged aggressive nationalism and a desire for expansion. Industry grew rapidly during the late 1800s and early 1900s and brought great wealth to the industrialists. But workers resented what they considered an unequal distribution of profits. In addition, many middle-class and upper-class Germans had lived comfortably under the monarchy, and they feared and disliked the newly formed democratic government. Finally, many Germans blamed their problems on Jews.

Hitler's aims were primarily nationalistic, but he also promised social revolution to win support from the masses. The Nazi Party grew rapidly in the postwar crisis. The military supported Hitler's ideas of discipline, order, and military conquest. The middle classes and farmers were attracted by the promise of social reform. Wealthy industrialists joined to fight Communism. Powerless people responded to ideas of racial superiority, anti-Semitism (prejudice against Jews), and German strength. By 1923, the Nazi Party had 17,000 members.

**The rise to power.** Nazism did not gain wide support until the Great Depression, a worldwide business slump, began in 1929. Discontented Germans then turned to Nazism in increasing numbers. Nazism promised economic help, political power, and national glory. Hitler's fiery personality and talents as an orator also had a strong influence. The Nazi Party grew into a huge political organization with special divisions for children, youth, women, and professional people. It even had soldiers called *storm troopers*, who terrorized opponents.

In the elections of 1932, the Nazis emerged as the strongest party in Germany. On Jan. 30, 1933, Hitler became chancellor (prime minister). He quickly moved toward dictatorship, outlawing civil liberties and all political parties except the Nazi Party. The Nazis took over the press, the radio, and the school system. In time, they established a totalitarian state—a government that permits no opposition. They organized a powerful secret police force called the Gestapo and set up concentration camps for anyone suspected of opposing Nazism. Jews
and members of other minority groups were also imprisoned in these camps, where the Germans either killed them or used them for forced labor.

**Expansion, war, and collapse.** Hitler and his followers hoped to make the Nazi state a world empire. In 1938, they began to carry out their plans. Germany annexed Austria in 1938. German forces occupied Czechoslovakia the following year. The Nazis attacked Poland later in 1939, and World War II began. The Nazis started a campaign to murder all European Jews. Hitler called this the “final solution.” About 6 million Jews died by firing squad, in gas chambers, or by other methods. About 5 million others, including Gypsies, political opponents of the Nazis, and Poles and other Slavs were also killed. These mass murders later became known as the Holocaust (see Holocaust). The United States, the United Kingdom, the Soviet Union, and other nations defeated Germany in 1945, and the Nazi government collapsed.

**Neo-Nazism.** A number of small neo-Nazi (new-Nazi) parties have been founded in Germany since the end of World War II. They have sought to reestablish Nazi principles and to regain the lands Germany lost in the war. They also worked to reunify East Germany and West Germany, the two political units into which Germany was divided from 1949 to 1990. Neo-Nazis have promoted anti-Semitism. Some have denied that the Holocaust occurred. Neo-Nazi parties have gained support from former Nazis and from discontented or unemployed youth. After Germany’s reunification in 1990, neo-Nazis began to make frequent attacks on foreigners. The most violent neo-Nazis have been gangs of young males.

Neo-Nazi movements have grown in other countries since 1980. In the United States, for example, neo-Nazi ideas are supported by Ku Klux Klan members, by the Nazi Party, and by Aryan Nation and other white-supremacist groups. These individuals and organizations promote racism and anti-Semitism and use violence against minorities.

**Nearsightedness**

See National Education Association of the U.S. Neagh, Lough. See Lough Neagh.

Neanderthals, nee AN duhr thawlz or nee AN duhr tahlz, were prehistoric human beings who lived in parts of Europe, Asia, and Africa from about 130,000 to 35,000 years ago. Many scientists classify Neanderthals as an early subspecies of Homo sapiens (wise human being). However, other scientists do not consider Neanderthals to be direct ancestors of modern human beings. The word Neanderthal comes from the Neander Valley near Düsseldorf, Germany. The first fossils identified as Neanderthal were found there in 1856. Similar fossils have been found at over 40 sites.

Neanderthals stood about 5 feet 2 inches (157 centimeters) tall and walked fully erect. They had heavy bones, slightly curved limbs, big browridges, and powerful teeth. Their average brain size was larger than that of modern people, but they seem to have relied more on their physical strength than on skillful use of their hands or on inventive use of tools. However, animal bones found with the Neanderthal fossils show that the Neanderthals were successful hunters in the subarctic environments of Europe. They lived in simple temporary shelters when following the animal herds and sometimes also in caves. At least some Neanderthals buried their dead with great care.

See also Prehistoric people (Neanderthals; picture).

**Near East** is a name given to a region that includes a part of Asia from the Mediterranean Sea to the eastern boundary of Iran, plus part of northeastern Africa. The British and French first called this region the Near East because it lay nearer to London and Paris than the Far East lay. Today, this region is usually called the Middle East (see Middle East).

Michel Le Gall

**Nearsightedness,** also called myopia, is a visual defect that causes blurred distance vision. Except in extreme cases, near vision remains clear. For the eye to form a clear image, the light rays reflected or given off by an object must come together on the retina, the light-sensitive tissue lining the back and sides of the eyeball. In most nearsighted people, the eyeball is longer than normal from front to back. As a result, light rays from a distant object meet in front of the retina. When the rays do strike the retina, they form a blurred image.

Studies have shown that people inherit a tendency to develop nearsightedness. But intense close-up visual activity may contribute to the development of the condition. Some babies develop nearsightedness by age 1, but the problem corrects itself as the eyes grow. Research indicates these individuals usually develop the defect again during or after adolescence.

Nearsighted people can wear concave glasses or contact lenses to clear up their distance vision. Concave lenses are thinner in the middle than at the edges. They bend light rays outward so that the rays meet on the retina. See Eye (picture: Nearsightedness).

A surgical procedure called radial keratotomy can correct nearsightedness. This procedure, developed in the mid-1970’s, flattens the cornea (clear tissue covering the eyeball) so that light rays passing through it meet on the retina. Laser surgery also can reshape the cornea and correct nearsightedness. However, the long-term results of these surgical procedures are unknown.

David E. Efrig
Rolling farmland covers much of Nebraska, which ranks among the leading states in agricultural production. Nebraska devotes a greater percentage of land to farming than any other state.

Nebraska  The Cornhusker State

Nebraska is one of the leading farming states in the United States. Yet it was once considered part of the "Great American Desert." The people of Nebraska, with their determined pioneer spirit, made the Nebraska "desert" a land of ranches and farms. They built irrigation systems and practiced scientific farming. Where crops could not be grown, Nebraskans grazed cattle. Today, farms make up 95 percent of the state's area—a greater percentage than in any other state. In the west, waving fields of golden wheat stretch as far as the eye can see. In north-central Nebraska, huge herds of beef cattle graze on enormous ranches. On the fertile farms of the east, farmers grow corn, soybeans, sorghum grain, and other crops. The farmers there also raise hogs and fatten cattle for market.

But Nebraska is more than a farming state. Such service industries as finance and insurance play a major role in Nebraska's economy. Omaha is one of the Midwest's leading centers of finance and insurance. Manufacturing, especially food processing, is also important to the state's economy.

Much of the history of Nebraska is the story of the tough, strong-willed Nebraska farmer. Many of the first farm settlers built homes of Nebraska sod because they found few trees on this grassy land. In the 1860s, the first great wave of homesteaders poured into Nebraska to claim free land granted by the federal government. Hard times, insect pests, and droughts discouraged many farmers, and they returned to the East or moved to the mining areas of Colorado and California.

The independent, pioneer spirit of the people of Nebraska also led them to adopt a unicameral (one-house) state legislature. Nebraska is the only state in the nation with a unicameral legislature. Lincoln is the capital of Nebraska, and Omaha is the largest city.

The name Nebraska comes from the Oto Indian word nebrathka. The word means flat water, and was the Indian name for Nebraska's chief river, the Platte. Nebraska's official nickname is the Cornhusker State. This nickname comes from corn, the state's leading crop, and from the cornhusking contests that were once held each fall in many rural communities.

Gerald R. Ford, the 38th President of the United States; and Malcolm X, a Black Muslim leader, were born in Omaha. Other famous Americans who have lived in Nebraska include political leader William Jennings Bryan; novelist Willa Cather; entertainers Johnny Carson and Henry Fonda; and Edward J. Flanagan, the Roman Catholic priest who founded Boys Town.

The contributors of this article are Donald R. Hickey, Professor of History at Wayne State College; and David Wishart, Professor of Geography at the University of Nebraska.
Omaha’s Central Park is a pleasant gathering place for people in the city. The Old Market rises in the background.

Interesting facts about Nebraska

The Cowboy Horse Race began in Chadron on June 13, 1893. John Berry won the nine-man race to Buffalo Bill’s Wild West show in Chicago, almost 1,000 miles (1,600 kilometers) away, in 13 days 16 hours. Berry won a prize of $1,000.

Nebraska has the largest planted forest in the United States. It covers about 22,000 acres (8,900 hectares) and is part of the Nebraska National Forest.

The National Museum of Roller Skating is located in Lincoln. It is the only museum in the world dedicated solely to roller skating, with exhibits on the sport and industry from 1819 to the present.

The largest mammoth fossil ever found was unearthed in 1922 near Wellfleet. Scientists have determined that the mammoth was 13 feet 4½ inches (4.07 meters) tall. The fossil is on display at the University of Nebraska State Museum in Lincoln.

Beef cattle provide Nebraska’s largest source of agricultural income. These ranchers are driving Hereford cattle to winter pasture.
Symbols of Nebraska
The state flag, adopted in 1925, bears the state seal. On the seal, adopted in 1867, a smith with a hammer and anvil stands for the mechanical arts. A settler's cabin, sheaves of wheat, and stalks of growing corn symbolize agriculture. A steamboat on the Missouri River and a train represent forms of transportation that helped speed the settlement of Nebraska. The Rocky Mountains rise in the background.

Nebraska (brown) ranks 15th in size among all the states and 3rd in size among the Midwestern States (yellow).

General information
Statehood: March 1, 1867, the 37th state.
State abbreviations: Nebr. or Neb. (traditional); NE (postal).
State motto: Equality Before the Law.
State song: "Beautiful Nebraska." Words by Jim Fras and Guy G. Miller; music by Jim Fras.

Land and climate
Area: 77,359 mi² (200,358 km²), including 481 mi² (1,245 km²) of inland water.
Elevation: Highest—5,426 ft (1,654 m) above sea level in southwestern Kimball County. Lowest—440 ft (134 m) above sea level in Richardson County.
Record high temperature: 118 °F (48 °C) at Minden on July 24, 1936, at Hartington on July 17, 1936, and at Geneva on July 15, 1934.
Record low temperature: −47 °F (−44 °C) at Camp Clarke, near Northport, on Feb. 12, 1899.
Average July temperature: 76 °F (24 °C).
Average January temperature: 23 °F (−5 °C).
Average yearly precipitation: 22 in (56 cm).

For information about tourism, write to: Department of Economic Development, Tourism Division, P.O. Box 98907, Lincoln, NE 68509-8907. The Web site at visitnebraska.org also provides tourism information.
The state’s official Web site at www.state.ne.us also provides a gateway to much information on Nebraska’s economy, government, and history.

Nebraskans voted to adopt a one-house legislature.
Nebraska adopted Initiative 300, which prohibits corporations from buying farms or ranches in the state.

1867  Nebraska became the 37th state on March 1.
1934  
1967  Nebraska adopted both a sales and an income tax.
1982  
People

Population. The 2000 United States census reported that Nebraska had 1,711,263 people. The population had increased about 8.2 percent over the 1990 figure, 1,578,385. According to the 2000 census, Nebraska ranks 38th in population among the 50 states.

About half of Nebraska's population live in the state's metropolitan areas (see Metropolitan area). The areas are Lincoln; Omaha, which extends into Iowa; and Sioux City, Iowa, which extends into Nebraska. For the populations of these areas, see the Index to the political map of Nebraska.

Omaha, the state's largest city, serves as the industrial and trade center of eastern Nebraska and western Iowa. Omaha is one of the nation's chief rail centers. Lincoln, the state's second largest city, is an educational, governmental, and retail shopping center. Bellevue, the state's third largest city, is a fast-growing suburb of Omaha. Grand Island is Nebraska's fourth largest city. It serves as an important manufacturing, food processing, and distribution center. Only 12 other Nebraska cities have more than 10,000 people.

During the early history of Nebraska, Germans were the main immigrant group. They accounted for about 15 percent of the state's population in 1900. Today Nebraska's largest population groups include people of German, Irish, English, Czech, and Mexican descent.

Schools. In the 1820's, the U.S. Army established Nebraska's first school, at Fort Atkinson (near present-day Fort Calhoun). During the 1830's and 1840's, missionaries of various religious faiths founded schools in eastern Nebraska to teach the Indians. The first legislature of the Nebraska Territory adopted a free-school law in 1853, one year after the territory was established. The state Constitution, adopted in 1857, provides for the present system of public education. Children must attend school from age 7 through 15.

The Department of Education supervises and administers the state's school system. The department consists of a State Board of Education and a state commissioner of education. The people elect the eight members of the State Board of Education to four-year terms. The members of the board appoint the commissioner. For the number of students and teachers in Nebraska, see Education (table).

Libraries. Nebraska's first library was established in 1820 at the Fort Atkinson military post. The Kansas-Nebraska Act of 1854 provided for a territorial library in Nebraska. This library later became the state law library. In 1871, Omaha established the state's first public library. The Legislature passed a law in 1877 providing state funds to support public libraries. The Nebraska Library Commission was set up in 1901. The commission promotes, develops, and coordinates library services in the state. Nebraska has about 250 public libraries.

The University of Nebraska-Lincoln Library has over 2.6 million volumes. It also houses special collections on American folklore and author Willa Cather. The Nebraska State Historical Society Library in Lincoln collects books and documents on the history of the region. Some other significant libraries include the Lincoln City Library in Lincoln, and the Creighton University and University of Nebraska libraries in Omaha.

Museums. The Joslyn Art Museum in Omaha has collections ranging from ancient to modern art. Among its displays are objects crafted by American Indians and examples of art from Western frontier days. The University of Nebraska's Sheldon Memorial Art Gallery in Lincoln displays modern American paintings and sculptures.

The University of Nebraska State Museum in Lincoln has one of the largest collections of fossils in the United States. Its exhibits include an exceptional display of prehistoric mammoth skeletons. The Nebraska State Historical Society maintains a Museum of Nebraska History in Lincoln and seven other museums, including the Fort Robinson Museum in Crawford, the George Norris Home in McCook, and the Willa Cather Historical Center in Red Cloud. The Strategic Air Command (SAC) Museum near Omaha has displays and shows about SAC. For information on other museums, see the Places to Visit section of this article.

Universities and colleges

Population density

About half of the people of Nebraska live in metropolitan areas. Eastern Nebraska includes the state's largest cities—Omaha and Lincoln—and is much more heavily populated than the west.
Every year, thousands of tourists drive along Nebraska highways that follow the historic Oregon and Mormon trails. Ruts left by the pioneers' covered wagons can still be seen along the roadsides. In western Nebraska, the forests and rugged rocks of the Pine Ridge are a camper's, bicyclist's, and hiker's paradise. Other scenic spots include the valleys of the Platte, Niobrara, Big Blue, Loup, and Republican rivers and the bluffs along the Missouri River. The lakes and streams of the Sand Hills area teem with fish. On the prairies, hunters bag pheasants, quail, and other birds as well as deer.

The Nebraska State Fair and the Nebraskaland Days and Buffalo Bill Rodeo are the state's most important annual events. The fair is held in Lincoln from late August to early September. It features exhibits of crops, farm machinery, household equipment, and livestock. Nebraskaland Days takes place in North Platte in June. It includes parades, old-time Wild West shows, and a rodeo. Almost every county has a fair during the summer, and many communities hold annual fall festivals.

Children dressed in traditional clothes at the Swedish Festival in Stromsburg

Places to visit

Following are brief descriptions of some of Nebraska's many interesting places to visit:

**Arbor Lodge**, in Nebraska City, was the 52-room mansion of Julius Sterling Morton, a Nebraska journalist and the founder of Arbor Day. The site has 250 species of trees and shrubs.

**Bellevue** is the oldest town in Nebraska. It was established about 1823 as a fur-trading center. Some of the town's buildings are more than 100 years old.

**Brownville** was a leading river port of the 1850's. Many colorful reminders of pioneer days still stand.

**Girls and Boys Town**, near Omaha, is a home for neglected and homeless children of all races and creeds.

**Great Platte River Road Archway Monument**, a museum near Kearney, spans Interstate 80 and features exhibits on the road's history and development of the West.

**Harold Warp's Pioneer Village** in Minden has an extensive collection of memorabilia from pioneer days.

**Museum of the Fur Trade**, near Chadron, has a large collection of Indian artifacts, early guns, and other fur trade relics.

**Scouts Rest Ranch**, near North Platte, was the home of Buffalo Bill, the famous scout and showman. His popular Wild West show rehearsed there.

**Stuhr Museum of the Prairie Pioneer**, near Grand Island, features a restored railroad town of the 1800's. A bank, general store, and post office are among 60 frontier buildings there.

**National forests and parklands.** Nebraska has two national forests, Nebraska in Blaine, Dawes, Sioux, and Thomas counties, and McKindie in Cherry County. The division of Nebraska National Forest that lies in Blaine and Thomas counties is the largest hand-planted forest in the United States. The Agate Fossil Beds National Monument in northwestern Nebraska contains deposits of animal fossils. The Homestead National Monument of America, near Beatrice, occupies the site of one of the first pieces of land claimed under the Homestead Act of 1862. The Scotts Bluff National Monument marks a landmark 800 feet (244 meters) above the North Platte River on the Oregon Trail. The spire at Chimney Rock National Historic Site rises about 500 feet (150 meters) above the North Platte.

**State parks.** Nebraska has eight state parks. For information on them, write to Director, Game and Parks Commission, Box 30370, Lincoln, NE 68509.
Annual events

January-May
Sandhill Crane Migration in Grand Island, Hastings, and Kearney (March); St. Patrick’s Day Celebration in O’Neill (March); Arbor Day, statewide (April); Willa Cather Spring Conference in Red Cloud (May).

July-August
Grundlovs Fest, or Danish Day, in Dannebrog (June); Swedish Festival in Stromsburg (June); North Platte Nightly Rodeo (June-July); Old Mill Days in Neligh (July); Oregon Trail Days in Gering (July); State Fourth of July Celebration in Seward (July); Fur Trade Days in Chadron (July); Wayne Chicken Show (July); Winnebago Pow Wow in Winnebago (late July); Czech Festival in Wilber (August); Nebraska’s Big Rodeo in Burwell (August); Omaha Pow Wow in Macy (August); John C. Fremont Days in Fremont (August).

September-December
Husker Harvest Days in Grand Island (September); Cowboy Poetry Gathering in Valentine (September); River City Roundup in Omaha (September); Oktoberfest in Sidney (October); Light of the World Pageant in Minden (December); Star City Holiday Weekend in Lincoln (December).
Land regions. Nebraska rises in a series of rolling plateaus from the southeast to the extreme southwest. The land rises from about 800 feet (240 meters) above sea level to over 5,400 feet (1,650 meters). Nebraska has two major land regions. These are, from east to west: (1) the Dissected Till Plains and (2) the Great Plains.

The Dissected Till Plains cover about the eastern fifth of Nebraska and extend into South Dakota, Iowa, Missouri, and Kansas. Glaciers once covered the Till Plains. The last glacier melted several hundred thousand years ago. It left a thick cover of rich, soil-forming material called till. A deep deposit of windblown dust called loess then settled on the till. Streams have dissected (cut up) the region, giving it a rolling surface. In the southeastern section of Nebraska's Till Plains, the action of the streams has exposed glacial materials on the sides of the valleys. The northern section of the Till Plains is known as the Loess Hills. Most of the Dissected Till Plains region is very well suited to farming with modern machinery.

The Great Plains region of Nebraska stretches westward from the Dissected Till Plains and extends into Wyoming and Colorado. A series of sand hills rises north of the Platte River in the central part of the region. The soil of the Sand Hills section consists of fine sand piled up by the wind. The sand was formed into low hills and ridges. The section covers about 20,000 square miles (51,800 square kilometers), making it the largest area of sand dunes in North America. Grasses that now cover the Sand Hills hold most of the sand in place. Sometimes, however, overgrazing by cattle and extension of irrigated cropland kill the grass cover. The wind then cuts great holes called blowouts into the hillsides. Most ranchers take care not to overgraze the land. The Sand Hills make fine cattle country because of the area's flowing streams, abundant well water, and excellent grasses. Some of the grass is cut as wild hay.

The soil of the Sand Hills acts like a giant sponge. It absorbs and holds most of the area's limited rainfall. The rainfall seeps down and creates vast underground reservoirs of ground water. Movement of the ground water makes it possible to pump irrigation water to the surface in areas around the Sand Hills.

A deep deposit of loess covers the central and southwestern parts of the Great Plains. Some of this loess country is rough and hilly. But in the southeast, a flat loess area covers about 7,000 square miles (18,000 square kilometers). This area, called the Loess Plain, is farmed even more intensively than the Till Plains.

North and west of the Sand Hills are the High Plains, which cover about 12,000 square miles (31,100 square kilometers). The High Plains in the west rise over one mile (1.6 kilometers) above sea level along part of the Wyoming border. The High Plains receive little rainfall. Farmers there must use irrigation or practice dryland farm.

Land and climate

The Sand Hills of west-central Nebraska are low hills and ridges consisting of fine sand piled up by the wind. Grasses that cover the Sand Hills keep most of the sand in place.

Land regions of Nebraska

GREAT PLAINS

DISSECTED TILL PLAINS

WORLD BOOK map
ing, methods that make the most of the limited rainfall (see Dry farming). Rough parts of the High Plains are used mainly to graze cattle. Some of the rough areas, including the beautiful Wildcat Ridge and Pine Ridge, are covered with evergreen trees. The highest point in Nebraska is 5,426 feet (1,654 meters) above sea level in southwestern Kimball County.

A small area of Badlands is found in northwestern Nebraska. There, the forces of nature have carved weird formations in the sandstone and claylike rocks. The Badlands have little economic importance, but ranchers use some of the area to graze cattle, and tourists marvel at the magnificent scenery.

**Rivers and lakes.** The great Missouri River forms Nebraska’s eastern and northeastern border. Nebraska’s principal river, the Platte, flows into the Missouri at Plattsmouth. The North Platte and South Platte rivers join near the city of North Platte and form the Platte. The North Platte River enters the state from Wyoming, and the South Platte enters from Colorado. The Platte River winds across central and southern Nebraska. In some places, it is as much as 1 mile (1.6 kilometers) wide. The Platte is too shallow for navigation. Nebraskans use the waters of the river and its branches for irrigation, recreation, and the production of hydroelectric power.

The Loup and Elkhorn rivers are the Platte’s most important branches. Both rise in the Sand Hills. The abundant supplies of ground water in the Sand Hills keep these rivers flowing the year around. The Loup is formed by the North, Middle, and South Loup rivers.

The Republican River enters southwestern Nebraska from Kansas. It flows near the southern edge of Nebraska for about 200 miles (320 kilometers), and then turns back into Kansas and empties into the Kansas River. Other branches of the Kansas River in Nebraska include the Big Blue and Little Blue rivers. These three branches of the Kansas River usually flow gently. But heavy rainstorms sometimes cause them to overflow and flood the countryside. This danger has been reduced by flood-control projects and by dams built for irrigation and generating electric power.

The Niobrara River flows into northwestern Nebraska from Wyoming. It winds across the northern part of the state. This narrow, swift river passes through many

### Average monthly weather

**Average January temperatures**

Nebraska winters can be extremely cold. The northeastern has the coldest weather. The west and extreme south are warmest.

**Average July temperatures**

Nebraska has hot summers with temperatures varying only slightly. The far west is cooler than the rest of the state.

**Average yearly precipitation**

Nebraska may have wide ranges of precipitation from year to year. Rainfall decreases steadily from east to west.

---

**Pine Ridge** is a beautiful, rugged area that forms part of the High Plains in northwestern Nebraska.
scenic spots. It joins the Missouri River in Knox County. Nebraska has more than 2,000 lakes. None of the natural lakes is very large. Hundreds of small, shallow lakes dot the Sand Hills. Lake McConaughy, Nebraska's largest lake, is artificially created. It covers about 55 square miles (142 square kilometers) and has a shoreline of 105 miles (169 kilometers). Lake McConaughy was formed on the North Platte River by Kingsley Dam.

Other important artificially created lakes on the Platte River irrigation and power system include Jeffrey and Sutherland reservoirs and Johnson Lake. Additional large artificially created lakes in Nebraska are Swanson Lake and Harlan County Lake on the Republican River, and Enders Reservoir and Harry Strunk Lake on branches of the Republican River.

**Plant and animal life.** Forests cover only about 2 percent of Nebraska. Common trees in eastern and central Nebraska include ashes, basswoods, boxelders, cottonwoods, elms, hackberries, locusts, oaks, walnuts, and willows. Pines and cedars are among the trees that grow in the western part of the state.

Tall prairie grasses, especially bluestem, grow in uncultivated parts of eastern Nebraska. Short grasses, such as grama and buffalo grass, cover the land in drier western regions. Eastern shrubs include wild plums and chokecherries. Evening primroses, phloxes, and violets bloom in the eastern regions in spring. During the summer, blue flags, cumbines, larkspurs, poppies, spiderworts, and wild roses thrive throughout the state. Goldrod and sunflowers brighten roadsides and fields in late summer.

Nebraska's animal life consists chiefly of mule deer and such small animals as badgers, coyotes, muskrats, opossums, prairie dogs, rabbits, raccoons, skunks, and squirrels. Game birds are plentiful in the state. They include ducks, geese, pheasants, and quail. Common fish in the state's waters include bass, carp, catfish, crappies, perch, pike, and trout.

**Climate.** Nebraska's climate ranges from extremely hot in summer to extremely cold in winter. The weather changes suddenly—and sometimes violently. Hot, moist breezes from the Gulf of Mexico occasionally make summer nights uncomfortably warm in eastern areas. Nebraska sometimes has violent thunderstorms, tornadoes, blizzards, and hailstorms.

Temperatures in Nebraska vary only moderately from one area to another. Temperatures average about 76 °F (24 °C) in July and about 23 °F (−5 °C) in January. The state's record high temperature of 118 °F (48 °C) was set at Geneva on July 13, 1934; at Hartington on July 17, 1936; and at Minden on July 24, 1936. Camp Clarke, near Northport, recorded the lowest temperature, −47 °F (−44 °C), on Feb. 12, 1899.

Rainfall decreases steadily from east to west. The east receives about 27 inches (69 centimeters) of rain yearly. Less than 18 inches (46 centimeters) fall in the west. The state has droughts in some years, floods in others. Most rain falls from April to September. The growing season ranges from about 165 days in the southeast to 120 days in the northwest. Snowfall averages almost 30 inches (76 centimeters) yearly in the east. The west generally has less snow.

**Economy.**

Nebraska is one of the leading agricultural states. Farms and ranches take up about 95 percent of the land—a higher percentage than in any other state. However, service industries, taken together, make up the largest part of Nebraska's gross state product—the total value of goods and services produced within a state in a year. Services and manufacturing benefit from the state's strong agricultural base. For example, the transport of agricultural goods by truck and rail contributes to the service sector, and processed foods are the leading manufactured product.

**Natural resources.** Soil and water are Nebraska's most precious natural resources, and they are carefully conserved. Farmers rotate their crops, and some practice terracing and other soil-saving methods to keep the soil from wearing out or washing away. Many dams have been built to provide water for livestock and irrigation. The dams are also used to help control the flow of rivers and to produce electric power.

Nebraska may have more underground water than any other state. It lies above the High Plains Aquifer, a layer of porous rock and other material filled with water. This huge underground "lake" spreads from Texas to South Dakota, with two-thirds of it beneath Nebraska.

**Soil.** A fertile silt loam covers eastern Nebraska. The soil of the Sand Hills, in central Nebraska, consists of loose sand. It drifts badly if plowed, but left untouched, it supports grasses on which cattle can graze. The High Plains in the west have a loamy soil.

</table>

*GSP = gross state product; the total value of goods and services produced in a year.
*Less than one-half of 1 percent.
*Figures are for 1996.

**Minerals.** Nebraska has few minerals. Fields of petroleum and natural gas lie chiefly in western and south-central Nebraska. Sand and gravel can be found along the Platte and Republican rivers and their branches. Limestone quarries lie along the Missouri River in the
southeast part of the state. Clay deposits are found throughout the state.

Service industries account for the largest portion of the gross state product of Nebraska. Many of the state's service industries are located in the Omaha and Lincoln metropolitan areas.

Community, business, and personal services make up Nebraska's leading service industry group. This industry group consists of a variety of economic activities, including private health care, data processing companies, engineering companies, law firms, and repair shops. Omaha is a national center for telemarketing companies, which service businesses by promoting and selling products by telephone.

Wholesale and retail trade ranks second in terms of its contribution to the gross state product. Wholesale trade consists of buying goods from producers and selling them to other businesses. The state's major wholesale goods include farm products and farm supplies. ConAgra, a major distributor of food products, is based in Omaha. Retail trade involves selling goods directly to consumers. Major retail businesses in Nebraska include automobile dealerships and grocery stores.

Finance, insurance, and real estate is Nebraska's third-leading service industry. Omaha is a Midwestern financial center. Mutual of Omaha, one of the largest insurance companies in the United States, is headquartered in the city. Omaha is also the home of Berkshire Hathaway, a large holding company of insurance companies and other businesses. The buying and selling of houses, farms, and other property make real estate an important activity in many parts of the state.

Ranking next among the service industries are government services and transportation, communication, and utilities. Government services include the operation of electric utilities, public schools, public hospitals, military bases, and Indian reservations. Nebraska is the only state in which publicly owned utilities provide all electric service. The public school system is a major employer in the state. The headquarters of the U.S. Strategic Command (STRATCOM) is at Offutt Air Force Base, near Omaha. In a nuclear war, STRATCOM would control all U.S. long-range bombers and missiles, as well as all U.S. ballistic missile submarine forces.

Railroad, shipping, and trucking companies are an important part of the transportation, communication, and utilities sector. These companies transport agricultural goods from farms to markets. Telephone companies are the most important part of the communications sector. Utilities provide gas and water service. More information about transportation and communication can be found later in this section.

Manufacturing. Goods manufactured in Nebraska have a value added by manufacture of about $11 billion yearly. Value added by manufacture represents the increase in value of raw materials after they become finished products.

Food processing is by far the leading manufacturing activity in Nebraska in terms of value added by manufacture. Meat products and grain products provide most of the income from food processing in Nebraska. The state is one of the world's major centers of meat packing. Dakota City, Fremont, Grand Island, Lexington, Omaha, and Schuyler have large meat-packing plants. The Omaha area is also the state's chief center for the processing of grain products. Breakfast cereal and livestock feed are the leading grain products. Other food products include baked goods, dairy products, and soft drinks.

Chemicals are Nebraska's second-leading manufacture. Nebraska's leading chemical products include pharmaceuticals, pesticides, and fertilizers.

Machinery ranks third among manufactured goods. The most important kind of machinery is farm equipment. Plants in Gering, Grand Island, and many other places manufacture farm equipment. Instruments and related products rank fourth among Nebraska's manufactured products. Scientific, medical, and surgical instruments are among the leading instruments produced. Other products manufactured in Nebraska, in order of value added, include electrical equipment, fabricated metal products, and transportation equipment.

Agriculture. Nebraska has about 55,000 farms. The leading farm products are beef cattle, corn, hogs, and soybeans. Nebraska ranks among the leading producers of all four of these products. The state has many irrigated farms, especially in the central region.

Nebraska's largest farms are the cattle ranches of the Sand Hills area, some of which cover up to 100,000 acres (40,000 hectares). The smallest farms are in the eastern and south-central sections of the state. They produce livestock, corn, wheat, oats and other field crops.

Livestock and livestock products provide about two-thirds of Nebraska's farm income. Beef cattle are the most important farm product in the state. The rich grasses that grow on the Sand Hills and in the west provide fine feed for range beef cattle. Ranchers ship calves to farmers in the eastern corn-raising areas. These farmers, called feeders, fatten the young cattle on corn and other grains. After fattening, the cattle are sent to livestock markets. Nebraska is one of the leading states in fattening cattle for market. Some farmers raise dairy cattle, and milk is another important source of farm income.

Hogs are the second most important livestock product in Nebraska. The Till Plains region of eastern Nebraska is one of the country's leading hog-producing areas.

The Mutual of Omaha Building, center, is the home of one of the largest U.S. insurance companies. The city ranks as one of the nation's centers of the insurance industry.
Economy of Nebraska

This map shows the economic uses of land in Nebraska and where the state’s leading farm and mineral products are produced. Major manufacturing centers are shown in red.

- Mostly cropland
- Woodland mixed with cropland
- Grazing land mixed with cropland
- Mostly grazing land
- Manufacturing center
- Mineral deposit

Egg farms are also found in this region. Crops provide about a third of Nebraska’s farm income. Corn, the state’s chief crop, is grown in the east and in irrigated areas. Much of the corn is used to feed cattle and hogs. The state’s other leading crops are soybeans, hay, grain sorghum, and wheat. Most of the soybean farms lie in the Till Plains region. Most of the hay is grown in the Great Plains region, especially the northern section. Southeastern Nebraska produces most of the grain sorghum. Most of Nebraska’s wheat farms lie near the state’s southern border. Other crops raised in Nebraska include barley, beans, sugar beets, oats, and potatoes.

Mining. More than a third of Nebraska’s mining income comes from petroleum. Most of the state’s crude oil is produced in Cheyenne, Hitchcock, Kimball, and Red Willow counties. Construction companies use sand and gravel from the Platte Valley. Manufacturers use clay from eastern Nebraska for bricks, tiles, and pottery. The state’s limestone is used in construction, in making cement, and in treating soil.

Electric power. Power plants that burn coal provide about 65 percent of the electric power generated in Nebraska. Nuclear plants at Brownville and Fort Calhoun supply approximately 30 percent of the state’s power. Most of the remaining power comes from hydroelectric plants.

Transportation. Thousands of pioneers crossed the Nebraska region on their way to the West. The Oregon, California, and Mormon trails followed Nebraska’s Platte River. In 1865, the Union Pacific Railroad began laying track westward from Omaha and became part of the first transcontinental rail system in the United States. Today, the Union Pacific and the Burlington Northern Santa Fe railroads provide most of the freight service in Nebraska. Passenger trains serve five cities.

Nebraska has about 39,000 miles (62,000 kilometers) of roads and highways. All highways and most roads are surfaced. Interstate 80 is the most important highway. It runs east and west between Omaha and the Wyoming border.

Nebraska’s busiest airport is at Omaha. Lincoln also has a large airport. Ports in Omaha, Nebraska City, and South Sioux City send and receive freight by water.

Communication. D. E. Reed began Nebraska’s first newspaper, the Nebraska Palladium and Platte Valley Advocate, in 1854. Today, Nebraska has about 190 newspapers, of which about 15 are dailies. The state’s leading daily newspaper is the Omaha World-Herald. Other Nebraska dailies with large circulations include the Lincoln Journal Star, the Grand Island Independent, and the Norfolk Daily News. Nebraska publishers also issue about 50 periodicals.

Nebraska has about 115 radio stations and 25 TV stations. Cable television systems and Internet providers service many communities throughout the state. Nebraska Wesleyan University established Nebraska’s first radio station, WCAJ, in Lincoln in 1921. The first commercial station, WOAW (now WOW), began broadcasting from Omaha in 1923. The state’s first television stations, KMTV and WOW-TV, started operations in Omaha in 1949.

Government

Constitution of Nebraska was adopted in 1875. Nebraska had one earlier constitution, adopted in 1866. Amendments may be proposed by the Legislature, by a constitutional convention, or by the people. An amendment proposed in the Legislature becomes law after approval by three-fifths of the Legislature and by a majority of voters casting ballots on the amendment, providing that these approving votes are no less than 35 percent of the total votes cast in the election.

A proposal to call a constitutional convention also must be approved by three-fifths of the Legislature and by a majority of voters casting ballots on the proposal, providing that these approving votes are no less than 35 percent of the total votes cast in the election. Convention proposals become law after they have been approved by a majority of people voting on them. The
The Nebraska Legislature meets in the State Capitol in Lincoln. Nebraska is the only state with a unicameral (one-house) legislature. Its 49 members are called senators.

people of Nebraska may sign a petition (formal request) proposing a constitutional amendment. The number of signatures on a petition must equal at least 10 percent of the number of registered voters on the date the signatures are to be turned in to the secretary of state. The proposed amendment becomes law after approval by a majority of voters casting ballots on the amendment, providing that these votes are no less than 35 percent of the total votes cast in the election. The people also have the power of referendum, which may be invoked, by petition, against acts of the Legislature.

**Executive.** Voters elect the governor, lieutenant governor, secretary of state, attorney general, treasurer, and auditor to four-year terms. The governor and treasurer may serve no more than two terms in succession. The other four officials have no term limits. Voters have elected the six top officials to four-year terms since 1966. Before then, they were elected to two-year terms.

**Legislature.** Nebraska is the only state with a unicameral (one-house) legislature. The 49 members of the Legislature are called senators. Voters in each of 49 legislative districts elect one senator. The people elect the senators on a nonpartisan ballot—that is, the ballot has no political party labels. Nebraska is the only state that chooses state legislators in nonpartisan elections.

The people approved a constitutional amendment in 1962 increasing the legislators’ terms from two years to four years. In the 1964 general election, 24 senators were elected to two-year terms and 25 senators were elected to four-year terms. Since 1966, half the senators have been elected every two years to four-year terms.

The Legislature meets every year. Regular sessions begin on the Wednesday after the first Monday in January. They are limited to 60 days in even-numbered years and 90 days in odd-numbered years. The governor may call special sessions.

**Courts** in Nebraska are headed by the state Supreme Court. It consists of a chief justice and one judge from each of the six judicial districts. The Court of Appeals has six judges, each representing one of the six judicial districts. Nebraska also has 12 district courts, with a total of 54 judges. A merit plan for selecting Supreme Court, appellate court, and district court judges went into effect in 1964. Under the plan, the governor appoints a judge to fill a vacancy in these courts from a list submitted by a nominating committee. Each judge appointed must be approved by the voters at the next general election after holding office for three years. If approved, he or she serves in the office for six more years. Thereafter, the voters must approve the judge every six years.

There are 12 districts in Nebraska’s county court system and 59 county judges. The state’s three most populated counties—Douglas, Lancaster, and Sarpy—have separate juvenile courts. There are nine juvenile court judges, who are selected and retained in the same manner as are judges of the state’s Supreme Court and district courts. No political party labels are allowed on the ballot used for approving judges.

**Local government.** Nebraska has 93 counties. About two-thirds of the counties have the commissioner-precinct form of government, and the remainder have the supervisor-territorial form. Counties that have the commissioner-precinct form are governed by a board of commissioners of three or five members. The commissioners are elected to four-year terms. Counties with the supervisor-territorial form are governed by a seven-member board of supervisors. The supervisors are also elected to four-year terms. Other officials in both kinds of Nebraska counties include the county clerk, treasurer, .

urer, sheriff, and attorney. Commissioners, supervisors, and all other elected county officials may serve any number of terms.

Nebraska has over 500 cities and villages. Most cities have the mayor-council form of government. Nebraska City uses the commission form, and a few cities use the council-manager plan. Most villages are governed by a five-member board of trustees. The Constitution gives home rule to cities with over 5,000 people. Such cities may operate under their own charters. Only Lincoln and Omaha have chosen to adopt their own charters.

Revenue. Taxes provide more than half of the state government’s general revenue (income). Most of the rest comes from federal grants and other U.S. government programs. The largest sources of state tax revenue are a general sales tax and a personal income tax. Other important tax revenue sources include taxes on motor fu-

gels, corporate income, motor vehicle licenses, insurance, and tobacco products.

Politics. All members of the Legislature, all judges and school officials, and many local officials are elected or approved on nonpartisan ballots. This system has weakened party politics in the state. However, in about three-fourths of the elections for president and two-thirds of the elections for governor, most Nebraskans have voted for Republicans. For Nebraska’s electoral votes and voting record in presidential elections, see Electoral College (table).

Two of Nebraska’s most famous citizens were national political leaders. William Jennings Bryan ran for president unsuccessfully three times. George W. Norris won fame as an independent politician during his 40 years in the United States House of Representatives and the United States Senate.

History

Indian days. A prehistoric people probably lived in the Nebraska region between 10,000 and 25,000 years ago. Scientists base this belief on the discovery of tips of stone tools and weapons, which were found buried in the Nebraska earth.

During the 1700’s, European explorers came across several Indian tribes in the Nebraska region. The Missouri, Omaha, Oto, and Ponca Indians lived peacefully, farming, hunting, and fishing along the rivers. The Pawnee hunted buffalo and grew corn, beans, and squash. They fought fiercely with other tribes, especially with the Sioux who lived to the north and the Comanche to the south. But the Pawnee were friendly with white settlers, and Pawnee scouts helped the U.S. Army in wars against the Sioux and Cheyenne. The Arapaho, Cheyenne, Comanche, and Sioux hunted in western Nebraska. They moved from place to place in search of game. To keep their hunting grounds, some Arapaho, Cheyenne, and Sioux resisted the white settlers.

Other Indian tribes moved into the Nebraska region as whites drove them from their homes in the East. The last Indians to settle in Nebraska were the Winnebago, who originally lived in Wisconsin. White people drove the Winnebago first to Iowa and then to Minnesota and South Dakota. In 1863 and 1864, the Winnebago fled into what later became Thurston County. The Omaha, Winnebago, and Santee Sioux now live on reservations in the state. The Pawnee, Oto, and Missouri Indians were forced from Nebraska in the 1870’s and 1880’s and migrated to what is now Oklahoma.

Exploration. In 1541, Francisco Vasquez de Coronado, a Spanish explorer, led an expedition across the American Southwest and into present-day Kansas. Spain claimed all this territory, including Nebraska, though the Spaniards made no settlements.

In 1682, the French explorer Robert Cavelier, Sieur de La Salle, traveled down the Mississippi River to its mouth. He claimed for France all the land drained by the Mississippi and its branches. La Salle named this vast territory, which included Nebraska, Louisiana, after the French king, Louis XIV. French traders and trappers moved into the Louisiana region during the 1690’s and early 1700’s. In 1714, a French explorer and adventurer, Etienne Veniard de Bourgmont, traveled up the Missouri River to the mouth of the Platte River.

Spain objected to French explorers in regions that it claimed, and decided to remove the French. In 1720, a Spanish expedition under Pedro de Villasur marched from Santa Fe into the Nebraska region. But the expedition met a group of Pawnee Indians along the Platte River and withdrew after being badly defeated.

Two French explorers, the brothers Pierre and Paul Mallet, traveled from French forts in Illinois to Santa Fe in 1739. They were probably the first whites to cross what is now the state of Nebraska.

The Louisiana Purchase. In 1762, France gave Louisiana to Spain. But French fur traders and trappers continued to operate in the Nebraska region, and the Spaniards never set up an effective government. In 1800, Napoleon Bonaparte, the ruler of France, forced Spain to return Louisiana to France. In 1803, he sold the Louisiana Territory to the United States. Nebraska, as part of the Louisiana Purchase, became part of the United States (see Louisiana Purchase).

American exploration and settlement. In 1804, President Thomas Jefferson sent an expedition under Meriwether Lewis and William Clark to explore the Louisiana Territory. Lewis and Clark traveled up the Missouri River and explored the eastern edge of Nebraska. Another American explorer, Zebulon M. Pike, visited the south-central part of Nebraska in 1806. Manuel Lisa, a Spanish-American trader, established fur-trading posts along the Missouri River between 1807 and 1820. One of these posts was Fort Lisa, about 10 miles (16 kilometers) north of present-day Omaha.

In 1812, Robert Stuart, a fur agent, set out for New York City from the Astoria fur-trading post in Oregon. Stuart and his party spent the winter in Wyoming and entered Nebraska early in 1813. They traveled along the North Platte and Platte rivers, and reached the Missouri River in April. Settlers moving to Oregon during the next 50 years followed the route explored by Stuart. This route became known as the Oregon Trail.

The U.S. Army established Fort Atkinson in 1819 on the Missouri River, about 16 miles (26 kilometers) north of present-day Omaha. The fort became the site of Ne-
braska's first school, library, sawmill, grist mill, and brickyard. The fort was abandoned in 1827.

In 1820, Major Stephen H. Long led an Army expedition across Nebraska through the Platte and North Platte river valleys. Long described the region of western Nebraska as "almost wholly unfit for farming." He called it the "Great American Desert."

During the 1820's, the American Fur Company and other fur companies set up trading posts at Bellevue and other points along the Missouri River. But until 1854, when Nebraska was made a territory, the federal government maintained Nebraska as Indian country. Except for Indian agents, missionaries, and licensed traders, no white families were allowed to settle there. In 1843, hundreds of pioneers began the "Great Migration" to the rich farmlands of Oregon. They followed the Oregon Trail through Nebraska to the West.

Territorial days. In 1854, Congress passed the Kansas-Nebraska Act, which created the territories of Kansas and Nebraska and opened the region to white settlement. Earlier bills to create the territories had been defeated because Congress could not agree on the slavery question. Northerners wanted to forbid slavery in all new territories, but Southerners wanted to permit it. The Kansas-Nebraska Act provided that the people of the new territories could decide for themselves whether to permit slavery. Most Nebraskans opposed slavery.

See Kansas-Nebraska Act.

The Nebraska Territory included what is now Nebraska and parts of Montana, North Dakota, South Dakota, Wyoming, and Colorado. President Franklin Pierce appointed Francis Burt of South Carolina as the first territorial governor. Burt died shortly after he took office, and the territorial secretary, Thomas B. Cuming, became acting governor. Cuming organized the territorial government and took a census so that elections could be held for the legislature. Nebraska had a population of 2,732 in 1854. By 1863, Congress had created several new territories from the region, and the Nebraska Territory was reduced to about the state's present area.

Many early settlers in the Nebraska Territory built their homes of sod because so few trees grew on the prairies. This sod was known as "Nebraska marble." Pioneers cut out blocks of sod with spades and piled the blocks on top of one another to form walls. Most roofs consisted of sod blocks supported by a mat of branches, brush, and long grasses.

Statehood. By 1860, Nebraska's population had grown to 28,841. In 1862, Congress passed the first Homestead Act. This act granted 160 acres (65 hectares) of free land in the West to settlers. A great rush for land followed. One of the first homesteads was claimed by Daniel Freeman in 1863 near the present city of Beatrice. The 1862 Homestead Act and similar acts brought many thousands of homesteaders to Nebraska. See Homestead Act.

In 1865, the Union Pacific Railroad began building its line west from Omaha. The Union Pacific and the Burlington railroads also started campaigns to bring more settlers to Nebraska. The railroads sent pamphlets describing the Nebraska farmland to people throughout the East, and even to Europe. These advertisements helped the population increase to 122,993 by 1870.

Early in 1867, Congress passed an act admitting Nebraska into the Union. In doing so, Congress overrode President Andrew Johnson's veto. Congress had required Nebraska to make certain changes in its Constitution. Johnson believed this action violated the U.S. Constitution. Johnson, a Democrat, also did not want Nebraska admitted into the Union because the territory had a Republican majority. The Republicans in Congress were trying to impeach Johnson, and the President believed that two additional Republican senators might have been enough to convict him. Nebraska became the 37th state on March 1, 1867. The people elected David Butler, a Republican, as the first governor.

In 1872, Nebraska became the first state to celebrate Arbor Day. Arbor Day is a special day set aside each year for planting trees. J. Sterling Morton, a newspaper publisher and political leader from Nebraska City, originated the idea of Arbor Day.

Growth of agriculture. The settlement of Nebraska slowed down between 1874 and 1877, when vast swarms of grasshoppers invaded the farmlands. The grasshoppers badly damaged oat, barley, wheat, and corn crops. Many settlers left their land and returned

Pioneer settlers, such as these shown on a farm near Ansley, were often called "sodbusters." They cut sod into blocks and used the blocks to build their houses because so few trees grew on the prairies.
Historic Nebraska

1682 Robert Cavelier, Sieur de La Salle, claimed the region drained by the Mississippi River, including present-day Nebraska, for France.

1714 Étienne Veniard de Bourgmont traveled up the Missouri River to the mouth of the Platte River.

1720 The Pawnee Indians defeated Spanish forces under Pedro de Villasur along the Platte River.

1739 Pierre and Paul Mallet were probably the first whites to cross Nebraska.

1762 France gave the Louisiana Territory to Spain.

1800 Spain returned Louisiana to France.

1803 The United States bought the Louisiana Territory, including Nebraska, from France.

1804 Meriwether Lewis and William Clark traveled up the Missouri River and explored eastern Nebraska.

1806 Zebulon M. Pike visited south-central Nebraska.

1813 Robert Stuart and his party followed the North Platte and Platte rivers across Nebraska.

1819 The U.S. Army established Fort Atkinson.

1843 The "Great Migration" began through Nebraska along the Oregon Trail to the West.

1854 Congress passed the Kansas-Nebraska Act, creating the Nebraska Territory.

1863 One of the first free homesteads was claimed by Daniel Freeman near Beatrice.

1865 The Union Pacific Railroad began building its line west from Omaha.

1867 Nebraska became the 37th state on March 1.

1874-1877 Vast swarms of grasshoppers invaded the Nebraska farmlands and severely damaged crops.

1905 The North Platte River Project was begun to irrigate 165,000 acres (66,770 hectares) in western Nebraska.

1934 Nebraskans voted to adopt a unicameral legislature.

1937 The unicameral legislature held its first session.

1939 Petroleum was discovered in southeastern Nebraska.

1944 Congress authorized the Missouri River Basin Project (now the Pick-Sloan Missouri Basin Program).

1960-1964 Nebraskans approved a series of constitutional amendments that strengthened the state government by raising salaries and increasing terms of government officials.

1967 Nebraska adopted both a sales and an income tax. It also celebrated its statehood centennial.

1982 Nebraska adopted Initiative 300, which prohibits corporations from buying farms or ranches in the state.

1992 Nebraska voters approve a state lottery.

The Oregon Trail ran along the Platte and North Platte rivers. Thousands of pioneers followed this route to the West during the mid-1800's.

The Union Pacific Railroad began building west from Omaha in 1865 to complete its part of the first U.S. transcontinental line.

Crazy Horse, the great Sioux Indian chief, surrendered to the U.S. Army at Fort Robinson on May 6, 1877.

One of the first homesteads in the United States, on a site near Beatrice, was granted to Daniel Freeman on Jan. 1, 1863.

Important dates in Nebraska

World Book illustrations by Kevin Chadwick
East. Farmers in the Midwest saw hundreds of wagons traveling east bearing such signs as "Eaten out by grasshoppers. Going back East to live with wife's folks." But another rush of farmers poured into the state during the 1880s. Prices for land soared higher and higher. In 1890, land prices collapsed because of drought, overuse of credit, and low prices for farm products. Farmers could not pay for land bought on credit at high prices.

The farmers blamed the railroads, banks, and other business organizations for their difficulties. Many farmers joined the Populist, or People's Party, which sought reforms to help farmers. The party achieved its greatest strength in Nebraska during the 1890s. Many Populists supported William Jennings Bryan, a Democrat and the state's leading political figure of the period. See Populism.

In the 1890s, Nebraska farmers started to use irrigation and dry-farming methods. Congress passed the Reclamation Act in 1902, authorizing federal aid for irrigation development. Three years later, construction started on the North Platte Project to irrigate 165,000 acres (66,770 hectares) in western Nebraska. The Kinkaid Act passed in 1904 and provided for 640-acre (259-hectare) homesteads in western Nebraska. But many settlers found much of the land unsuitable for farming. Cattle ranchers bought out most of the homesteaders and returned the land to grass.

Economic depression. A boom in farm prices ended during the early 1920s. Then, in 1929, the stock market crashed and farm prices fell still further. In addition, drought again hit the state. Many farmers faced bankruptcy and the loss of their land. Banks and insurance companies took over farmers' property because the farmers could not meet their mortgage payments. But so many families were affected that sheriffs often refused to carry out court orders for public sale of the land. During the Great Depression of the 1930s, the federal government provided long-term, low-interest loans and other aid to farmers.

In 1915, a committee of the Nebraska legislature had recommended a unicameral legislature. The committee believed that a one-house legislature would eliminate the delays and the shifting of responsibility that occurs in two-house legislatures. The unicameral legislature would be more economical, because there would be fewer members. The committee's recommendation formed the basis of discussions that lasted almost 20 years. In 1934, U.S. Senator George W. Norris of Nebraska sponsored an amendment to the state Constitution for the adoption of a unicameral legislature. The voters approved the amendment in November 1934. The new unicameral legislature held its first meeting in 1937.

The mid-1900's. Geologists discovered oil in southeastern Nebraska in 1939. Oil companies drilled many wells in the area during the early 1940s, and oil became the state's most important mineral.

During World War II (1939-1945), Nebraska farmers produced millions of tons of corn, oats, potatoes, and wheat to help meet wartime food shortages. The raising of beef cattle also expanded greatly. By 1947, Nebraska's farm income reached a record of more than $1 billion yearly.

In 1944, Congress approved the Missouri River Basin Project (now called the Pick-Sloan Missouri Basin Pro-
gram). This huge project calls for construction of flood control dams, hydroelectric plants, and reservoirs in Nebraska and other states drained by the Missouri River. Nebraska has already benefited from the project, though it is far from completion. See Missouri River.

In 1948, the Strategic Air Command (SAC) established its headquarters at Offutt Air Force Base near Omaha. The base, now home to the USSTRATCOM, has been important to the economy of Omaha. In 1949, geologists discovered oil fields in western Nebraska.

During the 1950s, Nebraska farms became larger in size but fewer in number. The increased use of machinery lessened the need for farmworkers, and many of these workers moved to towns and cities in search of jobs. By 1970, over 60 percent of Nebraska's people lived in urban areas.

The shift in population made Nebraska aware of the need to expand its industries and to attract new ones. In 1960, the voters approved an amendment to the state Constitution allowing cities and counties to acquire and develop property for lease to private businesses. Many new firms moved into Nebraska during the 1960s, partly as a result of the state's campaigns to attract industry. Employment in manufacturing increased 44 per cent in the 1960s.

During the 1960s, the state Legislature passed much important legislation. In 1963, it passed the Nebraska Education Television Act, and Nebraska became one of the first states to cover its entire area with educational television (ETV) broadcasts. In 1967, the Legislature adopted sales and income taxes to make up for the revenue that was lost when the people voted out the state property tax in 1966.

The underground command post of the United States Strategic Command is near Omaha. The center would direct all U.S. strategic nuclear forces in a nuclear war.

In 1982, Nebraskans adopted Initiative 300, an amendment to the state Constitution that bans corporations from buying farm or ranch land in the state. Initiative 300 was designed to preserve the family farm. But it has been criticized for keeping land prices down and slowing the development of corporation-owned feedlots.

In 1990, Nebraska's government passed a large tax increase to help finance public education. In a referendum, the voters approved the tax increase by a sizable margin. At the same time, they rejected a proposal to limit government spending increases to 2 percent a year. In 1992, the voters approved a state lottery to increase government revenues.

Recent developments. Nebraska still depends heavily on agriculture in spite of the rapid growth of manufacturing and service industries. The trend toward fewer but larger farms continues. Agricultural production also continues to increase through greater use of machinery, irrigation, and modern methods. Like other farm states, however, Nebraska has suffered from rising costs of operating farms and periodic declines in the market values of farm products. Donald R. Hickey and David Wishart

Nebraska, University of, is a state-supported coeducational university. It is made up of the University of Nebraska at Kearney (UNK), the University of Nebraska-Lincoln (UNL), the University of Nebraska at Omaha (UNO), and the University of Nebraska Medical Center (UNMC).

UNK has colleges of business and technology, fine arts and humanities, natural and social sciences, and education. UNL has colleges of agriculture, architecture, arts and sciences, business administration, journalism, engineering and technology, home economics, and law. UNL also has a teacher's college and a division of continuing studies. UNO has colleges of arts and sciences, business administration, education, fine arts, public affairs and community services, and continuing studies. Courses in engineering, technology, and home economics are also offered. UNMC has colleges of medicine, nursing, and pharmacy and a school of allied health pro-
Nebuchadnezzar II,  

Nebuchadnezzar II, nehb uh kuhd NEHZ uhr (630?-562 B.C.), reigned as king of Babylon and ruler of the New Babylonian Empire from 605 to 562 B.C. The New Babylonian Empire included much of the Middle East. Babylon, a city near present-day Al Hillah, Iraq, was the empire's capital. Nebuchadnezzar was one of the most famous kings of the ancient world. He is best remembered for conquering the city of Jerusalem and for his great building projects. His name is also spelled Nebuchadrezzar and Nabu-kudurri-usur.

In 597 B.C., Nebuchadnezzar captured Jerusalem, the capital of a Jewish kingdom called Judah (now part of Israel). He deposed the king of Judah and appointed another king. He also took payment and hostages. About 10 years later, Judah rebelled against Babylonian control. In 587 or 586 B.C., Nebuchadnezzar took the city of Jerusalem again. His army destroyed the city's Temple and palace, and sent many Jews to Babylon as prisoners. This period of Jewish history is called the Babylonian Exile.

Nebuchadnezzar launched many important building and renovation programs in Babylon. He built or improved a major palace, several temples, a monumental gate known as the Ishtar Gate, a "procession way," and a stepped tower called a ziggurat. He probably also built the Hanging Gardens of Babylon, one of the Seven Wonders of the Ancient World.

See also Babylon; Seven Wonders of the Ancient World (with picture).

Nebula, NEHB yuh luh, is a cloud of dust particles and gases in space. The term nebula comes from the Latin word for cloud. Early astronomers also used the term for distant galaxies outside the earth's galaxy, the Milky Way. Such galaxies, called extragalactic nebulae, looked like hazy patches of light among the stars. But modern telescopes showed that extragalactic nebulae are actually systems of stars similar to the Milky Way.

Today, most astronomers use the term nebulae only for the clouds of dust and gases in the Milky Way and other galaxies. They classify these masses into two general types: diffuse nebulae and planetary nebulae. Both types are also called gaseous nebulae.

Diffuse nebulae are the larger of the two types. Some diffuse nebulae contain enough dust and gases to form as many as 100,000 stars the size of the sun.

A diffuse nebula may occur near an extremely hot, bright star. The intense ultraviolet light from the star energizes the gas atoms of the nebula and enables the mass to emit light. A diffuse nebula of this kind is called an emission nebula.

The Great Nebula in the constellation Orion is a huge cloud of dust and gas that appears as a misty spot in Orion's sword. The nebula's bright central area is shown in this photograph.

Astronomers believe some emission nebulae are places where new stars are forming. Gravity causes a portion of a nebula's dust and gases to contract into a much smaller, denser mass. Pressure and temperature build up within the mass of dust and gases as contraction continues for millions of years. In time, the mass becomes hot enough to shine—and forms a new star.

A diffuse nebula also may occur near a cool star. In this case, the ultraviolet light from the star is too weak to make the nebula's gas atoms give off light. But the dust particles in the diffuse nebula reflect the starlight. Astronomers refer to this kind of diffuse nebula as a reflection nebula.

If a diffuse nebula occurs in an area that has no nearby stars, it either emits nor reflects enough light to be visible. In fact, its dust particles blot out the light from the stars behind them. Astronomers call such a diffuse nebula a dark nebula.

Planetary nebulae are ball-like clouds of dust and gases that surround certain stars. They form when a star begins to collapse and throw off the outer layers of its atmosphere. When viewed through a small telescope, this type of nebula appears to have a flat, rounded surface like that of a planet.

See also Astronomy (Discovering other galaxies); Galaxy; Milky Way.

Nebular hypothesis, NEHB yuh hrhy PAHTH uh syls, is a theory about the origin of the solar system. Pierre Simon Laplace, a French astronomer and mathematician, formulated the theory in the late 1700's. According to Laplace, the solar system developed from a huge, extremely hot, rotating nebula, a cloud of dust particles and gases. The nebula cooled and contracted, leaving behind successive rings of matter as it became smaller. These rings, in turn, cooled and condensed,
forming the planets. The remaining central core of the nebula became the sun.

Many of Laplace’s ideas have been greatly modified by new discoveries. But most astronomers believe the solar system did develop from a nebula. C. R. O’Dell

See also Earth (Formation of Earth); Laplace, Marquis de; Nebula.

**Neck**. See Skeleton; Giraffe (diagram); Throat.

**Necktie** is a band of material or a bow that is worn around the neck. The tie is the most visible item of men’s clothing, and it reflects the wearer’s personal tastes. The *four-in-hand* and *bow* ties worn today have been about the same style since they were first worn in the 1850’s.

Neckties originated in the neckcloths that men folded and wrapped around their necks, with ribbon tied over them to hold the ends in place. In the 1700’s, men wore a whalebone *stock*. They fastened it in back with a strap or buckle, and tied it in front with a bow or knot. The *cravats* of the 1600’s and 1700’s were often frilly and lace-trimmed. By the mid-1800’s, narrow string ties, knotted bow ties, and ascots had replaced the more elaborate cravat. By about 1870, most men began to prefer wearing the wider four-in-hand necktie during the day. They wore white bow ties in the evening. Black bow ties appeared in the early 1900’s. Today, necktie widths vary slightly in accordance with the styling of suit lapels.

Richard Martin

**Necrology, neh KRahl uh jee**, is a record of deaths, especially one kept by a church. Usually it shows the day, month, and year of the death. A necrology may be a list of persons who have died within a certain time. It also may be an obituary notice.

**Necropolis, neh KRAHP uh illz**, is a Greek word which means *city of the dead*—that is, a cemetery. Archaeologists and historians usually call the cemetery of an ancient city a *necropolis*.

Archaeologists have found large and well-known necropolises in Egypt, near such ancient cities as Memphis and Thebes. The tomb of Tutankhamen in the Valley of the Kings, near Luxor, is one of hundreds of tombs in the huge necropolis there (see Tutankhamen; Valley of the Kings). A necropolis also surrounds the pyramids at Giza. Another necropolis, dating from the Bronze Age, is at Hallstatt, Austria. Many necropolises have also been found in America. One at Paracas, an archaeological site in Peru, dates back to the days before the Inca ruled.

Ancient peoples often buried tools, weapons, and personal belongings with the dead. Sometimes they also carved or painted religious texts, information about the dead, and scenes from everyday life. Archaeologists and historians have learned much about ancient civilizations from necropolises.

Leonard H. Lesko

**Nectar** is a sugary liquid that is produced by flowering plants. Nectar is secreted from tissues called *nectaries* that are frequently in the flowers or other parts of flowering plants. Honey bees collect nectar to produce honey. While gathering nectar, bees usually spread pollen from one plant to another. Hummingbirds and many kinds of moths and butterflies also feed on nectar.

Richard C. Keating

See also Bee (Making honey).

**Nectarine, nehk tuh REEN or NEHK tuh reen**, is a fruit much like the peach. The only important difference be-

tween the two is that nectarines have smooth skins and peaches are fuzzy. They come from identical trees. Nectarines often originate from peach seeds, and peaches may come from nectarine seeds. Botanists do not know which originated first, nectarines or peaches.

James E. Pollard

**Scientific classification**. The nectarine is in the rose family, Rosaceae. It is *Prunus persica*.

See also Peach.

**Needle** is a simple-looking tool, with a fine point at one end and a tiny eye at the other. But needles are not easy to make. Each needle undergoes at least 20 production processes.

Sewing needles are made from coils of steel wire. These coils of wire are cut into pieces long enough for two needles by a wire straightening and cutting machine. The straightened wires are then ground to a point on each end on a grindstone. While the wires are being ground, they are held by a device which makes them turn all the time they are touching the grindstone. This turning makes the needle points fine and even.

After each end of the wire is ground to a point, the center section of the wire pieces is stamped by a machine. The machine stamps a flat place for the eyes. Next, the two eyes are punched in the middle of each piece of wire by another machine. A piece of wire is then run through the eyes. At this time, the needles are cut apart, leaving the needles hanging on the wire. Next, the heads, or eye ends, are rounded and smoothed. Finally, the needles are *tempered* (toughened), and polished, sorted, and packed.

Special needles are made for special uses. Sewing-machine needles are made with the eye near the point. In addition, they have a groove on one side, which acts as a guide for the thread that goes through the needle’s eye.

A sewing needle for people with poor vision has the eye split so that the needle can be threaded through the top. A *crochet hook* is a type of needle with a hook at the end. The thread is caught in the hook instead of going through an eye. Upholstery sewing needles and

![Illustration of a nectarine flower](image-url)
Different kinds of needles are made for special purposes. For example, a crochet hook has a hook to catch the thread. A heavy-duty needle is used to sew thick canvas or cloth for sails. Surgical needles are manufactured with thread attached to them for easy use in an operating room.

The basic needlepoint stitch is the cross stitch. It occupies a square area over an intersection of the canvas mesh. Other stitches create various patterns and designs. These stitches include the slanting basket weave and knotted styles, and the bargello, a long vertical stitch. Needlepoint may be worked in fine thread and small stitches called petit point, or in large stitches known as gros point.

There are dozens of needlepoint stitches, ranging from simple techniques to complicated ones. This photograph shows four popular stitches.

The neem tree produces olivelike fruits. Manufacturers use chemical compounds from the tree's seeds to make pesticides.
to 90 feet (27 meters) tall. It produces white, honey-scented flowers and olivelike fruits.

Seeds from the neem tree contain a compound called azadirachtin. People use azadirachtin along with other neem compounds to make pesticides. Such pesticides are environmentally safe and can help control more than 250 pests, including aphids, mites, and locusts. Manufacturers also use neem tree parts in such products as soap, toothpaste, and acne ointment.

People from south Asia have traditionally made a number of natural remedies from the neem tree. For example, they have produced antiseptic paste from the leaves to treat skin diseases and sores. Michael J. Tanabe

Scientific classification. The neem tree belongs to the mahogany family, Meliaceae. It is Azadirachta indica.

Nefertiti, neHF uhr TEE tee, was an ancient Egyptian queen, the wife of Akhenaten, a pharaoh (king) who ruled from 1367 to 1350 B.C. Akhenaten was the first pharaoh to preach monotheism (belief in one god). Nefertiti was a firm supporter of Akhenaten’s teachings and assisted him in the new religious ceremonies. Akhenaten and Nefertiti’s reign is called the Amarna Revolution because of the many changes in art, religion, and social practices they made.

Nefertiti is the subject of several sculptured portraits. A limestone head of her in the Berlin Museum and an unfinished head in the Egyptian Museum in Cairo are among the best known of these portraits. Leonard H. Lesko

Negative number. See Algebra (Positive and negative numbers).

Negev, NEH gehv, is the triangular southern half of Israel. It extends from Beersheba south to the port of Elat on the Gulf of Aqaba (see Israel [terrain map]). The Negev is a semidesert tableland from 1,000 to 2,000 feet (300 to 610 meters) above sea level. It includes both flatlands and limestone mountains. Much of the Negev is covered by a layer of fertile loam, but rainfall needed for growing crops is insufficient. The Israelis have farmed part of the Negev by irrigation. They have irrigated the land with water brought from the Sea of Galilee through the National Water Carrier, a system of pipelines, canals, and tunnels. The Israelis have also mined phosphates and copper in the Negev. Bernard Reich

Negligence is the legal term for carelessness. The law uses negligence as a test to determine whether a person involved in an accident is responsible for any loss or injury that occurs in the accident.

The law considers negligence the failure to act the way a reasonably careful person would act under the circumstances. But the law does not say what specific conduct is negligent. The decision is made by a judge or a jury after consideration of the circumstances of each case. In general, a person whose negligence harms or kills another person or damages that person’s property must pay compensation.

If the injured person was partly responsible for the occurrence, that person’s carelessness is considered contributory negligence. In some cases, the contributory negligence prevents the injured person from being awarded compensation. In other cases, the judge or jury may compare the injured person’s contributory negligence to the fault of the others involved. The injured person’s compensation may then be reduced in proportion to his or her share of the blame.

English and American law generally do not regard negligence as a crime. But in cases where someone is killed through negligence, the negligent person may be charged with a crime called manslaughter or negligent homicide. Edward J. Kleinik

Negotiable instrument, nih GOH shuh buhl, refers to a type of legal exchange or document that is either a promise or an order to pay money. Negotiable instruments can be used as evidence of indebtedness or as a substitute for money. A person holding a negotiable instrument is usually in a good legal position to collect from the person who signed it. The signer is called a maker or drawer. The use of negotiable instruments is regulated by the Uniform Commercial Code, which has been adopted in whole or in part by all 50 states.

Negotiable instruments have six characteristics: (1) they must be in writing; (2) they must be signed by a maker or drawer, who promises to pay money; (3) they must contain an unconditional promise or order to pay; (4) payment must be in money; (5) instruments must be payable on demand or at a specific date; (6) they must be payable to the bearer or to the order of a person.

Forms. Common forms of negotiable instruments include promissory notes, drafts, and checks. Promissory notes include bonds, certificates of deposit from banks, and real estate mortgage notes. Drafts include bills of exchange, bank drafts, cashier’s checks, money orders, and traveler’s checks.

Many instruments are not strictly negotiable but have some features of negotiable instruments. For example, instruments calling for the delivery of goods or property instead of money may possess many of the legal qualities of negotiability. Bills of lading and warehouse receipts are examples. A bill of lading is given for goods in transit. A warehouse receipt is given for goods in storage. Each of these instruments can be written so that the promise to pay is negotiable.

Endorsement. Negotiable instruments are usually transferred or handed over to another person by endorsement. An endorsement is a signature or other writing on the back of the instrument that indicates or proves the instrument has been transferred.

An endorsement may be written in different ways. If the holder of the instrument simply signs it, the endorsement is called in blank. A special endorsement or an endorsement in full names the person to whom payment is to be made. A restrictive endorsement forbids further transfer. A check signed “Pay to First National Bank only” is a restrictive endorsement.

Every endorser of a negotiable instrument is usually liable for its face value, if the maker does not or cannot
Negritos, *nih GREE tohz*, are peoples who live in small, isolated groups in Asia and northern Australia and who resemble Pygmies. They spread from the Andaman Islands of the Indian Ocean to the Malay Peninsula, the Philippines, Indonesia, New Guinea, and Australia. Like African Pygmies, Negritos have dark skin and tightly curled brown hair and are less than 5 feet (1.5 meters) tall. Negritos have traditionally lived by hunting and by gathering plants and fruits. Today, however, many Negritos are gradually becoming like people of the more complex societies.

Nehemiah, *NEE uh MY uh*, Book of, is a book of the Hebrew Bible, or Old Testament. It is named for an important Judean figure in ancient Palestine. Nehemiah was appointed governor of Judea by the ruling Persians, serving in that office from 445 to 433 B.C. and for several years after 432 B.C. His vigorous programs of political and religious reforms, which were recorded in the book, renewed and restored the faltering Jewish community in Palestine in the 400's B.C. See also Ezra, Book of; Bible (The Hebrew Bible).

Nehru, NAY roo or NEH roo, is the family name of a father and his son, daughter, and granddaughter who became distinguished in Indian public affairs. The father and the son prefixed their names with their caste name, pandit. Pandit also means scholar. The daughter, the first woman president of the United Nations General Assembly, used Pandit as her last name (see Pandit, Vijaya L.). The granddaughter, Indira Gandhi, became the first woman prime minister of India (see Gandhi, Indira). Her son Rajiv Gandhi also served as prime minister (see Gandhi, Rajiv).

Motilal Nehru, *MOH tih lohl* (1861-1931), came from a distinguished family in the province of Kashmir. He studied law at Muir College in Allahabad and founded a prosperous legal practice. He was at first a close friend of the English in India, a member of wealthy social groups, and a follower of Western ways. But in the 1920's, he was converted to the cause of Indian independence and became a follower of Mohandas Gandhi (see Gandhi, Mohandas K.) Nehru gave up his law practice and began to live in a simple manner.

He wrote the Nehru Report in 1928. It outlined a new constitution for India. In 1930, he became active in Gandhi's civil disobedience movement. His energetic efforts on behalf of freedom and several terms in prison weakened Nehru's strength, and he died the next year. Nehru was born in Agra.

Jawaharlal Nehru was the first prime minister of India. He served from 1947 until his death in 1964.

Jawaharlal Nehru was the first prime minister of India. He served from 1947 until his death in 1964.

served as prime minister from 1947 until his death. He dominated Indian affairs. He worked to establish a democracy and to improve living standards. He favored a state-controlled economy.

Nehru gained international recognition for opposing alliances with the great powers and for promoting neutrality (nonalignment). He advocated nonaggression and ending atomic bomb tests. But he was criticized when Indian forces seized Goa and other Portuguese territories in India in 1961.

Nehru acted as a spokesman for nonaligned nations in Asia and Africa. He favored admitting Communist China to the United Nations until Chinese forces attacked the Indian border in 1962.

Nehru and his father were fond and proud of each other, but occasionally disagreed. At one time, the father favored only dominion status for India, while the son demanded complete independence.

Nehru was born in Allahabad. He went to school in England and graduated from Harrow School and Cambridge University. He returned to India after his schooling and became active in politics. He supported Mohandas Gandhi's civil disobedience movement in 1920. Nehru served as general secretary of the All India Congress Committee in 1929. That same year, he was elected president of the Indian National Congress. He held that post again in 1936, 1937, and 1946. The British often imprisoned him for his nationalistic activities during this period. Nehru was a master of English, and his writings are widely read.

See also India (History).

Additional resources
Nelson, Horatio (1758-1805), was Britain's greatest admiral and naval hero. In 1805, he defeated the combined French and Spanish fleets at Trafalgar in the greatest naval victory in British history. His victory broke France's naval power and established Britain's rule of the seas for the rest of the 1800's.

Early life. Nelson was born at Burnham-Thorpe in the English county of Norfolk, on Sept. 29, 1758. His father was rector of the local church, and his mother was a member of the famous Walpole family. Nelson was a small, frail child. But he fell in love with the sea early in life and made up his mind to be a sailor. He spent much time piloting small boats on the river near his home. When he was 12 years old, his uncle, Captain Maurice Suckling, planned a voyage to the Falkland Islands. Nelson begged his family for permission to go along, and he was finally allowed to do so. He owed much of his early training to Captain Suckling, who had him transferred from time to time to ships engaged in different types of service. Suckling also encouraged him to study navigation and to practice boat sailing.

Joins the navy. At the age of 15, Nelson went aboard the Carcass as a coxswain (steerer). He served on that vessel in an expedition to the Arctic seas. On his return, he was sent to the East Indies on the Seahorse. On the East Indies voyage, he caught a fever that seriously damaged his health. But he became a lieutenant in the Royal Navy at 18.

In 1779, when not yet 21, he was given command of the frigate Hinchinbrook. He was known as a capable officer. His professional ability and his talent for getting along with his men helped him to rise rapidly in the service. A cruise to Central America brought on a second tropical illness and Nelson was sent home in feeble health.

Nelson was given duty on the North Sea as soon as he recovered from the fever. He was then assigned to service in Canadian waters and developed a great fondness for Canada, where the climate strengthened his health. Nelson was given command of the frigate Boreas, stationed in the West Indies in 1784. He spent three years there.

Nelson married the widow of Josiah Nisbet, an English doctor, in the West Indies in 1787. Prince William, who later became King William IV of England, gave the bride away at the wedding. Nelson was recalled from

horatio nelson led the british to victory over the french and spanish fleets at trafalgar in 1805.

nelson, britain's greatest naval hero, was fatally wounded in this battle, above right.

detail of Nelson falling (1825), an oil painting on canvas by Denis Dighton; National Maritime Museum, Greenwich, England
active service soon afterward. He remained on the retired list until soon after the outbreak of war with France in 1793.

Wounded at Calvi. In 1793, Nelson was placed in command of the Agamemnon and sailed to join the British fleet in the Mediterranean Sea. This voyage began seven years of almost continual warfare at sea. Nelson was one of the British commanders who blockaded Toulon, France, and captured Corsica. He was wounded at Calvi, on the Corsican coast, and lost the sight of his right eye.

Nelson next distinguished himself at the Battle of Cape St. Vincent in 1797. He served under Admiral Sir John Jervis, who defeated the combined French and Spanish fleets. Nelson was made a Knight of the Bath for his part in this victory. He had become a rear admiral a week before the battle. A few months later, Nelson led a small landing party in an attack on the strongly fortified port of Santa Cruz de Tenerife in the Canary Islands. The attack was a bold gamble, but unlike others, it failed. The British were driven off with heavy losses and Nelson's right arm was badly mangled up to the elbow. The arm had to be cut off in a crude amputation in a pitching boat, and Nelson was invalided home to England in great pain. But he soon returned to duty.

Battle of the Nile. Napoleon, victorious in Europe, began to gather a French fleet for an expedition to conquer Egypt. Nelson was sent to watch the French ships at Toulon. A storm came up, and under its cover the French ships escaped. Nelson followed it in a long and tiresome pursuit. He finally cornered the French ships in Abu Qir Bay. There, he attacked and almost destroyed the fleet on Aug. 1, 1798. This engagement is known to history as the Battle of the Nile. It cut off Napoleon's army in Egypt and ruined his Egyptian campaign. A year later, Napoleon deserted his army in Egypt and sneaked across the Mediterranean in a tiny ship. The victory over Napoleon in the Battle of the Nile made Nelson famous. He was made Baron of the Nile and given a large sum of money.

Nelson was wounded again in this battle, and he went to Naples to recover. Emma Lady Hamilton, wife of Sir William Hamilton, the British ambassador to Naples, fell in love with the battered, one-eyed, one-armed naval hero and became his mistress. Her influence over Nelson became so great that he disobeyed his orders to leave Naples and join a squadron in the Mediterranean. It was Nelson's good fortune that no British defeat resulted from his refusal to leave Naples. Nelson was condemned for his conduct, however, when he returned to England.

Battle of Copenhagen. Nelson became a vice admiral in 1801, and sailed for Copenhagen, Denmark, in the squadron of Admiral Hyde Parker. Britain had claimed the right to search neutral ships for contraband of war. However, Denmark refused to allow its ships to be searched. A council of war chose Nelson to make the attack on the Danish fleet. Admiral Parker later became doubtful of the attack's outcome. He signaled Nelson to retire. But Nelson clapped his telescope to his blind eye and studied the signal. "I really do not see the signal," he said to an aide. He ignored Parker's order and turned what might have been a defeat into a great victory. After the Battle of Copenhagen, he was given the title of viscount.

Victory at Trafalgar. Nelson was made commander in chief of the fleet in May 1803. Sailing on the flagship Victory, he once more went in search of the French. He found the French fleet at Toulon, but it slipped away from him. Nelson chased the French to the West Indies and back. It was more than two years before Nelson was able to bring the French fleet to battle off Cape Trafalgar on the coast of Spain, on Oct. 21, 1805 (see Trafalgar, Battle of). Nelson hoisted his famous signal, "England expects that every man will do his duty." With only 27 vessels, Nelson attacked the combined French and Spanish fleets. One of the great naval battles of all time followed. Napoleon's fleet, which had 33 warships, was destroyed.

Nelson was wounded at the height of the battle. He was carried below with a sharpshooter's bullet in his spine. Nelson died during the battle, but he lived long enough to know that the British fleet had defeated the French and Spanish fleets. Nelson's last words were, "Thank God I have done my duty."

One of Nelson's great characteristics as a commander was his willingness to give full credit to his officers and men. After the Battle of Copenhagen, he refused an honor given him by the City of London because he alone was to be honored. Nelson replied, "Never till the City of London thinks justly of the merits of my brave companions of the second of April can I, their commander, receive any attention from the City of London." The poet Robert Southey wrote of Nelson, "England has had many heroes. But never one who so entirely possessed the love of his fellow countrymen. All men knew that his heart was as humane as it was fearless ... that with perfect and entire devotion he served his country with all his heart, and with all his soul, and with all his strength. And therefore they loved him as truly and fervently as he loved England."

Nelson monument. After Nelson's death, he became such a hero in the United Kingdom that the government erected a large column topped with a statue of him in Trafalgar Square, which was named for Nelson's last battle. The monument, called Nelson's Column, is one of the most famous landmarks in London. See London (picture: Trafalgar Square).

Nelson, Thomas, Jr. (1738-1789), an American soldier and statesman, served as a Virginia delegate to the Continental Congress from 1775 to 1777 and again in 1779. He was one of the Virginia signers of the Declaration of Independence in 1776. During the Revolutionary War in America, Nelson commanded the Virginia militia and fought in the Battle of Yorktown in 1781. He also served as governor of Virginia that year. He was born on Dec. 26, 1738, in Yorktown, Virginia. He died on Jan. 4, 1789.

James H. Hutson
**Nelson, William Rockhill** (1841-1915), founded and built the Kansas City Star (Missouri Star), a crusading newspaper, in 1880. The Star campaigned against municipal corruption, and for civic reform and a rehabilitation program. This program gave Kansas City parks, broad boulevards, and an art gallery. Nelson was born in Fort Wayne, Indiana.

Joseph P. McKerns

**Nelson River** is the longest river in Manitoba. From its outlet at the northern end of Lake Winnipeg, it flows about 400 miles (640 kilometers) northeast to empty into Hudson Bay. It is the outlet of Lakes Winnipeg, Winnipegosis, and Manitoba, and the Winnipeg, Red, and Saskatchewan river systems. The watercourse to the head of the Saskatchewan's farthest tributary is 1,600 miles (2,580 kilometers) long. Once a transportation link for Hudson's Bay Company, the river is now a source of hydroelectric power. A power station at Kelsey Rapids supplies power to the nickel mines and refinery at Thompson, Man. Other stations are at Jeppeg, Kettle Rapids, Limestone Rapids, and Long Spruce.

John S. Brierley

**Neman River** is a waterway in eastern Europe. The Neman rises southwrest of the city of Minsk in Belarus. It flows generally westward through Belarus and Lithuania and empties into the Baltic Sea (see Europe [terrain map]). The Neman flows 582 miles (937 kilometers) through a landscape of lakes and forests. Its chief branches are the Viliya, Shchara, Sheshupe, and Merky rivers. The Neman is called the Nyoman in Belarus and the Nemunas in Lithuania. Its historical names include the Memel and the Niemen.

The Neman is frozen from late November until March. During the rest of the year, it is used for floating timber. Barges can sail up the Neman for about 400 miles (644 kilometers) from its source. A dam on the river near the city of Kaunas, Lithuania, has a hydroelectric power plant.

Leszek A. Kosinski

**Nematode, NEHM uh tohd,** is a group of slender worms. When viewed from the end or cut crosswise, nematodes are round. They are also called roundworms. Their bodies are usually pointed at the ends. Some are so small they can be seen only through a microscope, and others grow over 3 feet (91 centimeters) long. Most males are smaller than females.

Many species of nematodes live in soil and water. Some species live as parasites in plants. Others, including hookworms, lungworms, pinworms, trichinae, and filariae, live as parasites in human beings and in such animals as dogs, sheep, and horses. Nematodes cause disease in plants, humans, and domestic animals.

**Scientific classification.** Nematodes make up the phylum Nematoda.

David F. Oetinger

**Nene, NAY nay,** also known as Hawaiian goose, is a rare bird of Hawaii. It also is the official bird of Hawaii. Nenes measure 22 to 26 inches (56 to 66 centimeters) long and are brown with long, buff-colored neck feathers. They live in open country and feed chiefly on grass. The female lays three to six creamy-white eggs. In 1950, only about 50 nenes existed. Since then, the number has greatly increased due to breeding and protection programs. See also Bird (picture: Birds of Australia and the Pacific Islands); Hawaii (picture: The state bird).

**Scientific classification.** The nene is in the family Anatidae. Its scientific name is *Nesochen sandvicensis.*

Charles Walcott

**Neodymium, NEE uh DIHM ee uhm** (chemical symbol, Nd), is a metallic element belonging to the rare earth group. Its atomic number is 60, and it has an atomic weight of 144.24.

C. F. Auer von Welsbach of Austria discovered the element in 1885. He separated the so-called element di- dymium into neodymium and praseodymium.

Neodymium melts at 1021 °C, and boils at 3074 °C. It has a density of 7.003 grams per cubic centimeter at 25 °C. The metal can be prepared by electrolysis of its halide salts, or by the reduction of these salts by alkaline earth metals in the presence of heat. The ceramic industry uses salts of neodymium to color glass and in glazes. The metal is present in *missch metal,* an alloy with many uses, and in the important Nd-YAG laser.

Larry C. Thompson

**Neolithic Period.** See Stone Age.

**Neon** is a chemical element that makes up about 1 part per 65,000 in the earth's atmosphere. The British chemists Sir William Ramsay and Morris W. Travers discovered the element in the atmosphere while they were studying liquid air in 1898. Ramsay had predicted the existence of this gas in 1897. Ramsay and Travers named the gas neon, for the Greek word that means new.

Neon is used chiefly for filling lamps and luminous sign tubes. Its usual color in lamps is bright reddish-orange. The addition of a few drops of mercury makes the light a brilliant blue.

Many airplane beacons use neon light because it can penetrate fog. A number of airplane pilots have reported that neon beacons were visible for 20 miles (32 kilometers) when it was impossible for them to see other kinds of lights.

Neon lamps are made by removing the air from glass tubes and then filling them with neon gas. When about 15,000 volts of electricity are applied to the tube, an electric discharge occurs, and the tube glows fiery reddish-orange. Instead of a filament, a neon tube has two electrodes sealed within it. The neon forms a luminous band between these electrodes.

Commercially, neon is obtained as a by-product of liquid air manufacture. Neon liquefies under normal pressure at —246.048 °C, and it freezes at —248.67 °C. When air is liquefied at about —200 °C, neon is left behind as a gas. Neon is expensive, but very little is needed for lamps. Signs use 1 quart per 200 to 300 feet (1 liter per 64 to 97 meters) of tubing. Liquid neon is often used as a low-temperature refrigerant (cooling agent).

Neon is a colorless, odorless gas. It does not react readily with other substances, though it may form a compound with fluorine. Neon is classed as a noble gas.
Neon signs brighten entertainment and shopping areas. This hotel in Las Vegas, Nevada, has glowing signs to attract visitors. Stores often use neon signs to advertise products.

Its symbol is Ne. It has an atomic number of 10 and an atomic weight of 20.1797. Frank C. Andrews

Neonatology, nee oh nay TAHl uh jee, is the branch of medicine concerned with the care of infants during the first 28 days of life. The highest death rate in life occurs during this period, which is known as the neonatal period. A doctor who specializes in the care of newborn infants is called a neonatologist.

The major cause of neonatal death is premature birth—that is birth before the pregnancy reaches term. Birth occurs at term if it happens from the 38th through the 41st week of pregnancy. The more prematurely the baby is born, the less it weighs and the higher its risk of death. Most neonatal deaths occur among infants who weigh less than 5 1/2 pounds (2.5 kilograms) at birth. The average weight of a baby born at term is 7 1/2 pounds (3.4 kilograms). Many neonatal deaths also result from birth defects in the infant or medical problems of the mother, such as infectious diseases.

Many major medical centers have a neonatal intensive care unit. There, sick infants are usually cared for by a team of neonatologists, neonatal nurses, respiratory therapists, pediatric and surgical consultants, and other supporting staff. Advancements in neonatal intensive care have made it possible for infants born as much as 12 to 18 weeks prematurely to survive. Kwang-sun Lee

Neoplasms. See Tumor.

Neoplatonism, nee oh PLAY tuh nihz uhnm, was a dominant school of philosophy from the A.D. 200's to the 500's. Neoplatonism, which means New Platonism, developed from the philosophy of Plato. It also absorbed elements of Pythagorean, Aristotelian, and Stoic thought. Plotinus founded Neoplatonism. Other neoplatonists included his followers Porphyry and Proclus.

The Neoplatonists developed their philosophy from Plato's theory of forms. According to this theory, all things that can be perceived are only imperfect copies of forms, which are their perfect essence. Knowledge comes from grasping with the mind the essential form of a thing, rather than from perceiving with the senses its many incidental qualities. Plotinus went beyond this theory to divide Plato's realm of forms into various levels of reality. Each level depends for its reality on those above it.

Transcending all reality is The One, which is in itself unknowable. One cannot even say that The One is, because The One is beyond being. But The One expands or "overflows" into the levels beneath it, as light shines through darkness, becoming dimmer as it goes.

The highest level of reality is that of Intellect, in which forms exist as ideas beyond time and space. The next level, which is dimmer and less real, is that of Soul. Next is the level of Nature, which is the dark realm of material bodies. Beneath these levels is Matter, which Plotinus describes as "not-being" and as the principle of evil. We inhabit the lower levels but yearn to turn upward and return to the higher ones. Our souls can leave our bodies and "travel" to the realm of Intellect, where forms reside as ideas in the divine mind.

The Neoplatonists believed the purpose of philosophy is to escape from the attachment we feel to our bodies and physical environment. Thus, we achieve immortality by finding our true place in the world of forms.

Neoplatonism was an important philosophical movement. Plotinus influenced Saint Augustine in developing his principles of Christian theology. Proclus' views helped shape Christian negative theology, which points out the limits of human ability to comprehend a supreme being. Neoplatonist thought influenced Near Eastern philosophy as early as the A.D. 400's. The Neoplatonic emphasis on spiritual, as opposed to physical, beauty was important to the idea of platonic love during the Renaissance. S. Marc Cohen

Nepal, nuh PAWL, is a country in south-central Asia. The highest mountain range in the world—the Himalaya—and a region of hills and valleys cover about 80 percent of Nepal. The Tarai (or Terai)—a flat, fertile river plain along Nepal's border with India—covers the rest of the country.

Kathmandu is the capital of Nepal and its largest city. Mount Everest, the highest mountain in the world, rises 29,035 feet (8,850 meters) above sea level in the Himalaya on Nepal's border with Tibet, a region in China.

About 45 percent of Nepal's people live in the Tarai. The rest of the people live in the hills and valleys region or in the mountains. Patches of farmland lie among the mountains of Nepal. These cultivated areas account for only about 10 percent of the country's mountainous area, but almost all of the mountain people live there. Nepal is poor and undeveloped. The country also has a high rate of disease and illiteracy.
**Facts in brief**

**Capital:** Kathmandu  
**Official language:** Nepali  
**Area:** 56,827 mi² (147,181 km²). Greatest distances—east-west, 500 mi (805 km); north-south, 150 mi (241 km).  
**Elevation:** Highest—Mount Everest, 29,035 ft (8,848 m) above sea level. Lowest—150 ft (46 m) above sea level.  
**Population:** Estimated 2002 population—25,099,000; density, 440 per mi² (170 per km²); distribution, 89 percent rural, 11 percent urban. 1991 census—18,491,097.  
**Chief products:** Cattle, corn, rice, oilseeds, sugar cane, wheat.  
**National anthem:** "Rash triya Dhun" ("National Anthem").  
**Flag:** The flag has two crimson triangles trimmed in blue, one above the other. The top triangle features the moon and the lower one the sun, symbols of the long life of Nepal. It is the only nonrectangular country flag. See Flag (picture: Flags of Asia and the Pacific).  
**Money:** Basic unit—rupee. One hundred paisa equal one rupee.

**Government.** Nepal is a constitutional monarchy. A prime minister serves as head of the government. The king serves as head of state and commander in chief of the armed forces. Nepal's parliament consists of a 60-member National Council and a 205-member House of Representatives. The people elect the representatives to five-year terms. Thirty-five members of the National Council are elected by the house, 15 members are elected by an electoral college, and 10 are appointed by the king. Members of the National Council serve six-year terms.

The king usually appoints the leader of the largest party in the house as prime minister. The prime minister heads a council of ministers, whose members are appointed by the king on the advice of the prime minister. The council helps carry out government functions.

Nepal is divided into 75 districts for purposes of local government. Each district is divided into cities and villages. The people elect a committee and a committee head to administer each district, city, and village.

The Supreme Court is Nepal’s highest court. It consists of a chief justice and 14 judges. The chief justice is appointed by the king, upon recommendation of a constitutional council. The other judges of the Supreme Court are also appointed by the king, upon recommendation of a judicial council.

**People.** Most Nepalese are closely related to the peoples of northern India. Other Nepalese are of Tibetan descent. Still others are of mixed Indian-Tibetan descent. Most people live in small villages that consist of two-story houses made of stone or mud-brick.

About 80 percent of Nepal's people earn their living through farming and related occupations. Most farms produce barely enough to support one family. Nepalese farmers trade any surplus crops they raise for such important items as kerosene and salt. Other Nepalese make their living as carpet weavers, clothing manufacturers, or craftsmen. Still others work as merchants, for the government, or in the tourist industry.

The Sherpas and the Gurkhas, two Nepalese groups, are known for their special skills. The Sherpas, a Himalayan people, have won fame as guides and porters for mountain-climbing expeditions. Sherpa men and women carry heavy loads up to high altitudes. Many Gurkhas serve as soldiers in the British or Indian army.

Hinduism is the official religion of Nepal. However, the Nepalese have combined the beliefs and practices of Hinduism with those of Buddhism. Buddha, the founder of Buddhism, was born in Nepal about 563 B.C. The Nepalese people celebrate the festivals of both Buddhism and Hinduism, and Buddhist shrines and Hindu temples are considered equally sacred. Many of the people of Nepal also worship local gods and spirits and consult shamans (magical healers) in times of illness.

Nepal has few physicians, and such diseases as cholera, leprosy, and tuberculosis occur frequently. Since the early 1950’s, the government has greatly reduced malaria. This has enabled many Nepalese from the mountains to settle in the Tarai, where malaria used to be widespread.

Some Hindus in Nepal practice polygyny, a form of marriage in which a husband has more than one wife. Polyandry, the practice of a wife having more than one husband, occurs among some of the Tibetan groups in
summers. Steep rivers cut deep valleys through the snow-clad mountains of the Himalaya. Forests cover the mountains up to the altitude of about 12,000 feet (3,660 meters) above sea level. Only grasses, lichens, and moss can grow in the cold, dry air above this altitude.

Mountaineers in the Himalaya herd sheep. They also herd long-haired oxen called yaks. Some people claim that a mysterious creature called the Abominable Snowman, or Yeti, lives in the mountains.

The hills and valleys lie south of the Himalaya. The valleys have a cool climate, and rain falls heavily in summer. Winters are chilly but dry. Farmers on the hillsides and in the valleys raise many crops. The region's crops include corn, rice, millet, and wheat. The farmers of the hills and valleys tend herds of cattle, sheep, and goats. A wide variety of trees and bamboo grasses grow in thick forests in this region.

The Tarai lies in southern Nepal. It has fertile farmland. Farmers grow corn, jute, millet, rice, sugar cane, tobacco, and other crops. Livestock raised in the region includes cattle and water buffalo. The Tarai has a tropical climate. Its jungles and swamps provide a habitat for a variety of wild animal species, including crocodiles, elephants, deer, leopards, rhinoceroses, and tigers.

Economy of Nepal depends almost entirely on farming. Nepalese farmers attend small fairs and markets to trade their surplus crops for other items. Nepal has few railroads or paved roads. The lack of good transportation facilities makes large-scale trade difficult.

Roads link Nepal with India, Nepal's chief trading partner. Nepal exports carpets, clothing, rice, spices, and sugar. Principal imports include gasoline, kerosene, machinery, metals and metal products, and textiles.

Since the 1950's, large amounts of foreign aid have helped develop Nepal's economy. Several nations—including China, India, Switzerland, the United Kingdom, and the United States—have contributed money to Nepal. These funds have helped construct roads, maintain health centers, and start small industries. The Nepalese government spends hundreds of millions of dollars annually on development projects. About half of this money comes from foreign aid and loans.

Hundreds of thousands of tourists visit Nepal annually. Money spent by visitors from other countries has helped improve economic conditions in Nepal.

Nepal has deposits of coal, copper, gold, iron, and mica, but the country has few mines. Nepal's greatest natural resources are its forests and rivers. Some of its swift mountain currents have been harnessed to produce hydroelectric power, but most of the country still depends on firewood for cooking and heating.

History. Until the late 1700's, Nepal consisted of a number of small, independent kingdoms. About A.D. 400, the Kathmandu Valley, where the Nepalese capital is now located, came to be called Nepal. Through the centuries, bands of conquerors, nomads, and refugees moved into Nepal. They came from Central Asia, India, and Tibet and were the ancestors of the Nepalese.

In the mid-1700's, Prithwi Narayan Shah, a king from a small Nepalese kingdom called Gorkha, began a military campaign to unify the country. By the time of his death in 1775, he had conquered most of what is now Nepal. He took the title of king of Nepal, and his descendants

Kathmandu, Nepal's capital and largest city, lies at the foot of the Himalaya. Many-storied temples called pagodas, such as the ones shown here, line many of Kathmandu's streets.

northern Nepal. In most such cases, the woman marries two or more brothers. The children who are born of such marriages regard the oldest husband as their father and his brothers as uncles.

Illiteracy ranks as one of Nepal's most serious problems. For the country's literacy rate, see Literacy (table: Literacy rates for selected countries). Tribhuvan University is Nepal's only university. It includes a main campus in Kathmandu and many other campuses in the country.

About half of the people speak Nepali—the country's official language—as their native tongue. Most of the rest of the people use Nepali as a second language. Nepali is related to the languages of northern India. More than 50 other languages and dialects are spoken in the country.

Land and climate. Nepal has three principal regions: (1) the Himalaya, (2) the hills and valleys, and (3) the Tarai. Differences in altitude give each region a different climate. Each region also has its own kinds of plants and animals.

The Himalaya, in the north, covers much of Nepal. The mountains have long, harsh winters and short, cool

Porters on a mountain-climbing expedition carry heavy loads up a steep trail in Nepal. The country's rugged mountains attract thousands of climbers and hikers yearly.

have served as monarchs ever since.

In the early 1800's, Nepal fought a war against the United Kingdom. Nepal had attempted to expand its boundaries into northern India. The British East India Company, a trading corporation, controlled much of India at that time, and British soldiers guarded India's borders. The United Kingdom declared war on Nepal in 1814 after Nepalese troops attacked a British outpost. The British expected an easy victory, but the Nepalese were accustomed to fighting in the mountains. Although the British initially suffered heavy losses, they defeated the Nepalese in 1816. After the war, the United Kingdom and Nepal became allies. The Gurkha soldiers of the Nepalese impressed the British, and the United Kingdom has recruited Gurkhas for its armies since that time.

In 1846, a political leader named Jung Bahadur seized control of Nepal's government. He took the honorary title of Rana and declared that a member of his family would serve as prime minister from then on. The Rana family totally controlled the government until 1951. During this period, the king had no power. The Ranas dominated the army, imprisoned their opponents, and even killed rivals whom they considered dangerous.

During the 1930's and 1940's, opposition to Rana rule grew. A revolution began in Nepal in 1950. The revolution overthrew the government and restored the monarchy to power under King Tribhuwan in 1951.

During the early 1950's, the government attempted to create a democracy. King Tribhuwan died in 1955. He was succeeded by his son, Mahendra. Mahendra criticized the rivalry among political parties in democratic systems. In 1960, he declared that Nepal needed a political system that would suit its traditions. He dissolved the elected government and took over power. Political parties were banned. In 1962, he put into effect a constitution that established the panchayat system, in which most power is held by the monarch.

Under Mahendra's rule, the government stressed economic development, tourism, road construction, and hydroelectric power. Mahendra died in 1972, and his son, Birendra, succeeded him as king.

In 1979, many Nepalese staged violent demonstrations, in part to demand a more democratic government. In response to the demands, Birendra allowed a national vote on the government system. By a narrow margin, the voters chose to continue Nepal's system.

In 1990, violent demonstrations calling for more democracy broke out again. The king lifted the ban on political parties, and an interim government was formed. In November 1990, a constitution was approved that made Nepal a constitutional monarchy. In May 1991, democratic parliamentary elections were held in Nepal for the first time since the 1950's.

In 1996, Communist rebels began fighting to replace Nepal's constitutional monarchy with a Communist government. By the early 2000's, rebels controlled several districts and were active in much of the country. Both the rebels and the national security forces used ruthless violence and intimidation against the people of Nepal.

In 2001, King Birendra's son Dipendra killed the king and most of the royal family, then himself. Gyanendra, the king's brother, took the throne.

Nephrite. See Jade.

Nephritis, ˌnəfrəˈtɪs, formerly called Bright's disease, is a general term for several inflammatory diseases of the kidneys. Glomerulonephritis is the disease most often called nephritis. It involves an inflammation of the glomeruli (filtering units) of the kidneys. The inflammation often reduces the amount of urine produced by the kidneys, causing waste products normally eliminated in the urine to accumulate in the body. Severe or persistent glomerulonephritis can cause serious, permanent damage to the kidneys.

Most cases of glomerulonephritis follow an infection of the throat or skin caused by certain types of the bacteria called streptococci. In some people, such infections apparently cause the body to become allergic to the tissues of the glomeruli. The glomeruli may suffer serious damage as a result. If this damage occurs rapidly, the condition is called acute glomerulonephritis. If the damage continues over a period of years, the condition is called chronic glomerulonephritis.

Acute glomerulonephritis occurs mostly in children. Symptoms include facial swelling, fever, headache, high blood pressure, vomiting, and blood and proteins in the urine. There is no specific treatment. Nearly all patients recover from their first attack of acute glomerulonephritis, but many have later attacks of the disease. Chronic glomerulonephritis develops mostly in adults. In most cases, the specific cause is unknown. Many cases involve only mild symptoms so that a person may not even know that he or she has the disease. For some patients, treatment with medications can stop or even reverse the damage. But for many others, chronic glomerulonephritis causes progressive, incurable kidney damage. Advanced stages may lead to kid-
ney failure and a potentially fatal condition known as uremia (see Uremia). In order to prevent advanced uremia, physicians may connect the patient to a dialysis machine, which removes wastes from the patient’s blood. Physicians may also treat chronic glomerulonephritis with ambulatory dialysis, in which the patient manually drains and replaces abdominal fluids. In certain severe cases of the disease, physicians may perform a kidney transplant to replace the damaged kidneys.

Nepotism, NEHP uh tihz uhm, is the practice of giving important political or business positions to members of one’s family. The word nepotism comes from the Latin word for nephew.

Neptune was the god of the sea in Roman mythology. He had power over the sea and seafaring. For example, he could cause—or prevent—storms at sea. Neptune resembled the Greek god Poseidon. Like Poseidon, he was also the god of earthquakes and horses.

The ancient Romans were a seafaring people and imported much of their food and other necessities by ship. As ruler of the sea, Neptune thus had an important role in their daily life. Sea travel was dangerous in ancient times, and Roman sailors prayed to Neptune for safe voyages. After their return, sailors often showed their gratitude by dedicating a valuable object to Neptune.

Neptune was the son of Saturn and Ops (called Cronus and Rhea by the Greeks). He married the sea nymph Amphitrite, and they had a son, Triton, who was half man and half fish. Triton played an important role in many ancient legends about the sea.

Neptune appears in a famous episode at the beginning of the Aeneid, an epic by the Roman poet Virgil. In this epic, Neptune calms a storm that threatened to destroy the fleet of the Trojan hero Aeneas. Many ancient and modern seascapes feature Neptune, Amphitrite, and Triton. Artists portray Neptune as a man carrying a trident (three-pronged spear). Some show him riding in a chariot pulled by seahorses and accompanied by dolphins. Many fountains, notably the Trevi Fountain in Rome, include a statue of Neptune. One of the planets is named for him. Daniel P. Harmon

See also Poseidon.

Neptune is one of the two planets that cannot be seen without a telescope. The other is Pluto. Neptune is about 30 times as far from the sun as is Earth. Pluto is the only planet farther from the sun than Neptune. But every 248 years Pluto moves inside Neptune’s orbit for about a 20-year period, during which it is closer to the sun than Neptune. Pluto last crossed Neptune’s orbit on Jan. 23, 1979, and remained within it until February 11, 1999.

Neptune’s diameter is about 30,500 miles (49,100 kilometers), or almost 4 times that of Earth. It is about 17 times as massive (heavy) as Earth, but is not so dense as Earth (see Mass; Density). Neptune has eight satellites (moons) and several rings around it.

Neptune travels around the sun in an elliptical (oval-shaped) orbit. Its mean distance from the sun is about 2,798,800,000 miles (4,504,300,000 kilometers). Neptune goes around the sun once about every 165 earth-years, compared to once a year for Earth. As Neptune orbits the sun, it spins on its axis, an imaginary line through its center. Neptune’s axis is not perpendicular (at an angle of 90°) to the planet’s path around the sun. The axis tilts about 3° from the perpendicular position (see Planet illustration: The axes of the planets). Neptune spins around once in about 16 hours and 7 minutes.

Surface and atmosphere. Scientists believe that Neptune is made up chiefly of hydrogen, helium, water, and silicates. Silicates are the minerals that make up most of Earth’s rocky crust, though Neptune does not have a solid surface like Earth. Thick clouds cover Neptune’s surface. Its interior begins with a region of heavily compressed gases. Deep in the interior, these gases blend into a liquid layer that surrounds the planet’s central core of rock and ice. The tilt of its axis causes the sun to heat the Neptune’s northern and southern halves alternately, resulting in seasons and temperature changes.
Bright blue clouds that surround Neptune consist mainly of frozen methane. Winds that carry these clouds may reach speeds up to 700 miles (1,100 kilometers) per hour.

Neptune is surrounded by thick layers of clouds in rapid motion. Winds blow these clouds at speeds up to 700 miles (1,100 kilometers) per hour. The clouds farthest from Neptune's surface consist mainly of frozen methane. Scientists believe that Neptune's darker clouds, which lie below the clouds of methane, are composed of hydrogen sulfide.

In 1989, the Voyager 2 spacecraft found that Neptune had a dark area made up of violently swirling masses of gas resembling a hurricane. This area, called the Great Dark Spot, was similar to the Great Red Spot on Jupiter. But in 1994, the Hubble Space Telescope found that the Great Dark Spot had vanished.

Satellites and rings. Neptune has eight known satellites. Only two of them—Triton and Nereid—can be seen by telescopes on the earth. The other six satellites and several rings around the planet were discovered by Voyager 2 in 1989.

Triton, Neptune's largest satellite, is 1,681 miles (2,705 kilometers) in diameter and about 220,440 miles (354,760 kilometers) from Neptune. It is the only major satellite in the solar system that orbits in a direction opposite to that of its planet. Triton has a circular orbit and travels once around Neptune every six days. Triton may once have been a large comet that traveled around the sun. At some point, Neptune's gravity probably captured the comet, and it became a satellite of Neptune. Scientists have discovered evidence that volcanoes on Triton once spewed a slushy mixture of water and ammonia. This mixture is now frozen on Triton's surface. Triton has a surface temperature of −390 °F (−235 °C), the coldest known temperature in the solar system. Some volcanoes on Triton remain active, shooting crystals of nitrogen ice as high as 6 miles (10 kilometers) above the moon's surface.

Nereid is much smaller than Triton, measuring only about 211 miles (340 kilometers) across. It travels in a long, elliptical orbit at an average distance of 3,425,900 million miles (5,513,400 kilometers) from Neptune.

Neptune has three conspicuous rings and one faint ring. All of these rings are much fainter and darker than the rings of Saturn. They appear to consist of particles of dust. Neptune's outer ring is unlike any other planetary ring in the solar system. It has three curved segments that are brighter and denser than the rest of the ring. Scientists do not know why the dust is spread unevenly in the ring.

Discovery. Neptune was discovered by means of mathematics before being seen through a telescope. Astronomers had noticed that Uranus, which they thought was the most distant planet, was not always in the position they predicted for it. The force of gravity of some unknown planet seemed to be influencing Uranus.

In 1843, John C. Adams, a young English astronomer and mathematician, began working to find the location of the unknown planet. Adams predicted the planet
Neptunium

**Neptunium** (symbol, Nehp) is an artificially created element. Its atomic number is 93. Its most stable isotope has an atomic weight of 237 and a half-life of 2 million years. Neptunium was discovered by Edwin M. McMillan and P. H. Abelson at the University of California in 1940. Neptunium was named for the planet Neptune. It follows uranium in the periodic table of the elements, just as Neptune follows Uranus in the solar system (see Element, Chemical). Neptunium was first produced by bombarding uranium with slow neutrons. Neptunium produced in this way is unstable and decays to form an isotope that can be used for nuclear fission. Scientists have created much neptunium in nuclear reactors and have studied its physical and chemical properties. Neptunium metal has a density of 20.25 grams per cubic centimeter at 20 °C. It melts at 639 °C. Richard L. Hahn

**Nereids, NIHr ee ihdz**, were 50 beautiful sea nymphs who attended the sea divinities Poseidon and Amphitrite. They were the daughters of the sea goddess Doris and of Nereus, called the Old Man of the Sea. The Nereids lived under the sea and surfaced to dance in the waves. Their leader was Thetis, mother of the hero Achilles. Other famous Nereids included Psamathë and Galatea. Nancy Felson

See also Nereus; Andromeda.

**Nereus, NIHr oos**, was a kindly old sea god in Greek mythology. The poets Homer and Hesiod called him the Old Man of the Sea. Like other sea deities, Nereus had the gift of prophecy and the ability to change shapes. He foretold the fall of Troy in the Trojan War. The Greek hero Heracles (Hercules in Latin) captured him while he slept and held him fast as he rapidly changed forms. After Nereus finally resumed his original shape, he told Heracles where to find the garden of the Hesperides. The hero then set him free. With the sea goddess Doris, Nereus fathered 50 lovely sea nymphs called the Nereids. See also Hesperides; Nereids. Nancy Felson

**Nerl, NAIR ee, Saint Philip** (1515-1595), was the founder of the Oratorians, and a refomer of Rome during the Counter Reformation. Pope Gregory XIII recognized his group of priests as the Congregation of the Oratory in 1575. Nerl, a popular leader, also won over cardinals and popes to his unusual methods of reform. He was born in Florence, Italy. Marvin R. O'Connell

**Nero, NEER oo** (A.D. 37-68), was a Roman emperor who reigned from A.D. 54 until his death 14 years later. His rule is best known for a fire that destroyed much of Rome in A.D. 64. Nero built the Golden House, a colossal palace, in the center of the burned-out area. There were rumors circulating that Nero had started the fire so that he could build the palace. However, Nero blamed the Christians, then an unpopular group in Rome, and persecuted them.

Nero was born in Antium. His given and family names were Lucius Domitius Ahenobarbus. His father, Gnaeus Domitius Ahenobarbus, was a nobleman. Nero's mother was Agrippina the Younger, the great-granddaughter of Emperor Augustus. Nero's father died when Nero was still a child, and Agrippina married Emperor Claudius in A.D. 49. Claudius adopted Nero as his eldest son, naming him Nero Claudius Caesar Drusus Germanicus. In A.D. 53, Nero married Octavia, Claudius's daughter by a previous marriage. The next year, Claudius died. Many historians believe that Agrippina poisoned him so that Nero could become emperor.

At first, Nero permitted two respected advisers to direct state affairs. These advisors were Seneca, a philosopher and writer, and Burrus, a military officer. However,
Neruda was born in Perral, Chile. His real name was Neftali Reyes. He first gained recognition with the lyrical and romantic Twenty Poems of Love and One Desperate Song (1924). The two parts of Residence on Earth contain his poetry from 1925 to 1935. They show the poet at his most surrealistic. Although not all their symbols are comprehensible, their vision of disintegration and despair are unmistakable. Neruda showed a new desire to make art speak for oppressed members of society in Third Residence (1947) and General Song (1950). His most playful and eloquent poems appear in Elemental Odes (1954).

Naomi Lindstrom

Nerval, nehr VAL, Gérard de, zhay RAR duh (1808-1855), was a French poet. His charm, odd behavior, periodic mental disorders, and mysterious suicide made him a hero typical of the romantic movement. Critics consider him a major visionary poet.

Nerval believed in metempsychosis, the passing of a soul at death from one body to another. In Les Chimeres (1854), a collection of sonnets, this belief underlies many obscure references to the legendary past which contribute to the haunting beauty of the poems. His search for the eternal feminine ideal is reflected in the short stories of Les Filles du Feu (1854), notably in "Sylvie," a tale set in the Valois countryside. Aurelia (1855), a prose confession, begins with the phrase "Our dreams are a second life." It describes this "life," including the hallucinations Nerval suffered during his periods of insanity. He was born in Paris.

Jean-Pierre Cauvin

Nerve. See Nervous system.

Nerve gas. See Chemical-biological-radiological warfare.

Nervi, NEHR vee, Pier Luigi, pyehr loo EE jee (1891-1979), was an Italian architect and engineer. His designs reflect his belief that practical industrial structures should be beautiful and elegant through simplicity of design. Nervi was trained as an engineer, and he felt that architectural beauty could be derived from mathematical calculations rather than from aesthetic considerations. Nervi became especially noted for his free and graceful use of reinforced concrete. He developed a number of new structural techniques that utilized concrete.

Nervi was born in Sondrio. His first major work was a stadium completed in Florence in 1932. It has stairways that dramatically curve out over open space. Nervi designed two concrete exhibition halls (1948-1950) in Turin. Both were largely prefabricated. Nervi’s other buildings include two Sports Palaces designed for the 1960 Summer Olympic Games in Rome, and the Palace of Labor (1961) in Turin. For pictures of Nervi’s designs, see Rome (picture: The Sports Palace and the introduction to Architecture).

Nicholas Adams

Nervous breakdown is a term often used to refer to anything from fatigue caused by overwork to a severe mental illness. The term has no precise medical meaning. Psychiatrists and others who study and treat mentally ill patients do not use the term. It is used by those who believe it is an accepted medical term, or who want to avoid using the term “mental illness.” The original idea behind the term was that mental symptoms of a person were caused by a failure of the nerves to function properly.

Paula J. Clayton

See also Mental illness.

Nero began to assume his own power in A.D. 59. That year, he had Agrippina murdered. In A.D. 62, Burrus died, and Seneca retired from political life. Soon afterward, Nero divorced Octavia and then had her killed so he could marry Poppaea Sabina. Poppaea was the former wife of a Roman military officer. Nero killed her a few years later. He also executed many Roman senators because they questioned his actions. These executions and Nero’s scandalous life made him increasingly unpopular with the upper classes. A plan to overthrow Nero failed. As a result, more aristocrats were killed in A.D. 65.

Nevertheless, most of Rome’s provinces were well governed and peaceful. Nero’s military commanders put down rebellions in Britain and Judea and reassured Rome’s right to choose the king of Armenia.

Nero appreciated Greek civilization. He was a poet and actor and took an interest in architecture. In A.D. 66 and 67, Nero toured Greece and participated in games and festivals there. By then, military commanders in the provinces had begun to fear Nero’s cruelty and wild suspicions. In A.D. 68, they revolted. Nero took his own life soon afterward. His last words were said to have been, “Alas, what an artist is dying in me.”

William G. Sinnigen

Neruda, nay ROOD uhh, Pablo, PAH bloh (1904-1973), a Chilean poet, won the 1971 Nobel Prize for literature. Because he continually changed his approach to poetry, Neruda’s work cannot be easily characterized. He was one of the great adapters of surrealism in Spanish-language verse, producing obscure, violent imagery and conveying a sense of universal chaos (see Surrealism). Neruda also experimented with making poetic expression as direct and simple as possible.
Nervous system is an internal communications network that enables an animal to adjust to changes in its environment. Almost all animals, except the simplest kinds, have some type of nervous system.

Animals without a backbone have a nervous system that ranges from a simple net of nerves to a highly organized system of nerve cords and a primitive brain. In human beings and other animals with backbones, the nervous system consists of the brain, the spinal cord, and the nerves. This article deals mainly with the human nervous system.

The human nervous system—especially the highly developed brain—makes people different from all other animals. The human brain functions much like a complicated computer that enables people to think, solve difficult problems, and produce creative ideas.

The nervous system provides pathways by which information travels from a person's surroundings to the brain. The brain then sends instructions to various muscles via other pathways so that the body can respond to the information. The nervous system also regulates internal functions, such as breathing, digestion, and heartbeat. All of a person's movements, sensations, thoughts, and emotions are products of his or her nervous system.

How the nervous system works

The nervous system is made up of billions of special cells called neurons or nerve cells. Cordlike bundles of neuron fibers are called nerves. The nerves form a network of pathways that conduct information rapidly throughout the body.

A person's reaction to a situation may take only an instant, but it involves many complicated processes within the nervous system. For example, what happens in the nervous system of a person who sees a wild tiger and, an instant later, turns and runs away?

Specialized neurons called receptors are located in the ears and eyes and the other sense organs of the body. The receptors translate events in a person's surroundings—such as the sight of a tiger—into nerve messages, which are known as impulses. Nerve impulses travel along nerve fibers at speeds of 3 to 300 feet (0.9 to 90 meters) per second.

The receptor cells in the eyes respond to light rays that reflect off the tiger and translate the rays into a pattern of nerve impulses. These impulses then travel through neurons called sensory neurons and association neurons. The sensory neurons carry information from receptors in the sense organs to the association neurons, which are located in the brain and the spinal cord.

The neurons in the brain receive the impulses, analyze and interpret the message, and decide what action should be taken. A message consisting of the sight of a wild tiger is, of course, interpreted as danger. The person's brain immediately sends out a message—"Run"—in the form of nerve impulses.

Next, the impulses travel through motor neurons. These nerve cells carry messages from the brain to the muscles and glands, which are called effectors. The effectors carry out the brain's instructions. Thus, the leg muscles respond and the person runs away. At the same time, the brain sends messages to various other parts of the body. For example, it sends messages to the heart to beat faster and send more blood to the leg muscles.

Divisions of the nervous system

The nervous system has three main parts, the central nervous system, the peripheral nervous system, and the autonomic nervous system. Each of these parts has special functions.

The central nervous system functions as a "main switchboard" that controls and coordinates the activities of the entire nervous system. The central nervous system consists of the brain and the spinal cord.

The brain is an extremely complicated organ. It consists of three principal parts, the cerebrum, the cerebellum, and the brain stem. This article provides basic information about the brain. For more detailed information on the brain and how it works, see the World Book article on Brain.

The cerebrum makes up about 85 per cent of the brain and is the most complex part. It is above the cerebellum and the brain stem and almost surrounds them. Human beings have a highly developed cerebrum that directs their hearing, sight, and touch and their ability

How the nervous system works

The nervous system enables us to adjust to changes in our surroundings. Such neurons (nerve cells) as the receptors in the eyes translate information from the environment into nerve impulses. Sensory neurons carry the impulses to association neurons in the brain and spinal cord. Motor neurons then carry instructions from the brain to muscles, internal organs, and other body parts.
ways that relay commands from the brain to the motor neurons.

The peripheral nervous system carries all the messages sent between the central nervous system and the rest of the body. The peripheral nervous system consists of 12 pairs of nerves that originate in the brain, plus 31 pairs of nerves of the spinal cord. These cranial and spinal nerves serve as "telephone wires" that carry messages to and from every receptor and effector in the body.

The autonomic nervous system is a special part of the peripheral nervous system. The autonomic nervous system regulates such automatic bodily processes as breathing and digestion without conscious control by the brain. This constant regulation enables the body to maintain a stable internal environment.

The autonomic nervous system has two parts, the sympathetic system and the parasympathetic system. The sympathetic system responds to the body's needs during increased activity and in emergencies. The actions of the sympathetic system include speeding up the heartbeat, sending additional blood to the muscles, and enlarging the pupils of the eyes to use all available light.

The parasympathetic system, in general, opposes the actions of the sympathetic system. The parasympathetic system's functions include slowing down the heartbeat, diverting blood from the muscles to the stomach and intestines, and contracting the pupils of the eyes. The balance of activity between the two systems is controlled by the central nervous system.

Parts of a neuron

A neuron has three basic parts, the cell body, the axon, and the dendrites. A thin nerve membrane surrounds the entire cell.

The cell body of a neuron is a ball-shaped structure about \( \frac{1}{1000} \) of an inch (0.025 millimeter) wide. Each neuron cell body is a center for receiving and sending nerve impulses. The cell body is also responsible for making proteins and using energy for the maintenance and growth of the nerve cell.

The vast majority of neuron cell bodies are within the central nervous system, where incoming messages are combined and outgoing messages are produced. The few neuron cell bodies outside the central nervous system are grouped into clusters called ganglia. The best-known ganglia are in the autonomic nervous system.

The axon, also called the nerve fiber, is a tubelike extension of a neuron cell body. The axon is specialized to carry messages. An axon of one neuron may have enough branches to make contact with as many as 1,000 other neurons.

Most axons in the central nervous system are less than \( \frac{1}{4} \) of an inch (1 millimeter) long. However, many axons in the peripheral nervous system are longer, and some are much longer. For example, the axons that extend from the spinal cord to the muscles in the feet may be 30 to 40 inches (76 to 100 centimeters) long.

The structures commonly called nerves are actually bundles of axons lying next to one another in a cordlike formation. Nerves can be made up of the axons of motor neurons or sensory neurons, or of both.

Some axons are covered by a sheath of a white, fatty substance called myelin. The myelin increases the speed
of impulses along the axons. Myelin also causes the distinction between the gray matter and white matter in the nervous system. Gray matter consists largely of unmyelinated axons (axons without myelin sheaths) and neuron cell bodies. White matter is made up mostly of axons that have white sheaths of myelin. Myelin is formed in the peripheral nervous system by Schwann cells, which are special supporting cells that surround the axons. In the central nervous system, supporting cells called glia produce myelin.

The dendrites of a neuron are branching, tubelike extensions of the cell body that form a pattern resembling the limbs of a tree. Most neuron cell bodies have about six main dendrites, each of which is two or three times as thick as the axon of the cell. The distance between the cell body and the tips of the dendrites is about \( \frac{1}{2} \) of an inch (0.5 millimeter).

Dendrites are specialized structures for receiving impulses, mostly from the axon of another neuron. Dendrites and axons do not quite touch each other. In almost all cases, they are separated by an extremely narrow space called the synaptic cleft, over which nerve impulses are transmitted. These places where one neuron communicates with another are called synapses.

How messages are routed

Simple pathways. Much of the work of the nervous system depends upon established pathways between neurons. These pathways are called neural circuits. The simplest kind of neural circuit is a reflex. A reflex is an automatic and involuntary response to a stimulus. Simple reflexes do not involve the brain. Impulses in a reflex action follow a simple pathway that goes through the spinal cord and links a receptor and an effector.

One of the simplest reflexes is the knee jerk reflex. A tap on the tendon below the kneecap stretches the muscle there, and this action stimulates special receptors to produce an impulse. The impulse travels through a sensory neuron, over an axon to the spinal cord, and through a synapse to a motor neuron. There, a second impulse is generated. The second impulse travels over the axon of a motor neuron back to the muscle that was stretched. The impulse causes the muscle cells to contract and the leg to jerk.

Complex pathways. Many reflexes are more complicated. They involve at least one association neuron between the sensory and motor neurons. The association neuron, in turn, may be connected with many complex neural pathways, some of which may lead to the brain. A common but complex reflex is involved in withdrawing from a painful stimulus. For example, if a person steps on a sharp object, the immediate response is to lift the foot. In addition, association neurons stimulate the muscles of the other leg to adjust and maintain balance. Interconnecting neural pathways to the brain also may be stimulated so that the person becomes aware of what has happened.

Reflexes alone cannot account for the vast number and variety of actions performed by human beings. People, as well as some other kinds of animals, can learn new behavior patterns. Voluntary muscular movements necessary for learning new skills travel along complex nerve pathways that extend from the brain throughout the body. Complicated actions, such as riding a bicycle or walking, eventually can be performed without constant, conscious control after they have been learned.

How neurons carry impulses

During the 1800s, scientists discovered that nerve impulses involve electrical charges. They assumed a nerve
impulse was simply an electric current flowing through nerves. By the 1900s, researchers had learned that different concentrations of certain ions in neurons and in their surrounding fluids create a potential electrical charge. It was also learned that nerve cell membranes have pores that allow only certain substances to pass through. Scientists then theorized that a nerve impulse was an electrochemical process controlled by the nerve cell membrane.

In the 1930s, researchers developed techniques to test the membrane theory of nerve conduction, which is the theory discussed in this section. This theory is the accepted explanation of how neurons carry impulses.

**The beginning of an impulse.** A nerve cell membrane has special protein molecules that control the opening and closing of its pores. When at rest, the membrane keeps the concentration of sodium ions in the neuron very low. The membrane also keeps the concentration of potassium ions and negative organic ions much higher in the cell than in the surrounding fluids. These differences in ion concentration make the inside of the neuron more negative than the outside, and so the membrane is said to be polarized. The resulting voltage difference across the membrane is called the resting potential.

A chemical, electrical, or mechanical stimulus applied to a neuron can affect the membrane’s porosity and change the resting potential. The stimulus can cause the membrane’s pores to open and allow more sodium ions into the cell. The increase in sodium ions makes the inside of the cell positively charged, and this voltage change is called a depolarization.

When a stimulus causes a neuron to depolarize, the neuron is said to fire. The firing is the start of a nerve impulse. A stimulus must be of a certain intensity, called the threshold voltage, for a neuron to fire.

All impulses from a particular neuron have the same size and duration, no matter how large the stimulus that caused the neuron to fire. The fact that neurons fire at maximum strength or not at all is called the all-or-nothing phenomenon. The brain probably detects the intensity of a stimulus by the frequency of impulses generated and the number of nerve fibers stimulated.

**Conduction along the axon.** The inside of an axon is filled with a solution that can conduct an electric charge. Depolarizations in one area of an axon spread through the solution to neighboring areas along the axon. This wave of depolarizations is called an action potential.

If the axon of a neuron has no myelin sheath, the nerve impulse sweeps continuously along the axon, like fire along a firecracker fuse. But in a myelinated axon, nerve impulses can occur only at the nodes of Ranvier. The nodes of Ranvier are areas along an axon where the myelin sheath is interrupted at regular intervals. The impulse hops from node to node.

**Transmission across synapses.** Certain chemicals, called neurotransmitters, transmit nerve impulses across synapses. When an impulse reaches the end of an axon, a neurotransmitter is released into the synaptic cleft. The neurotransmitter moves to the dendrites of the next nerve cell and causes certain pores of the nerve membrane to open. Ions move through these pores, and a voltage change, called a postsynaptic potential, results.

The postsynaptic potential is either excitatory or inhibitory. An excitatory postsynaptic potential spreads to the axon of a nerve cell and tends to produce another action potential. An inhibitory postsynaptic potential tends to prevent the axon from producing another ac-

---

**Transmission of a nerve impulse**

A resting neuron is polarized—that is, its inside is more negative than its outside. The membrane maintains the polarity by restricting the flow of ions in and out of the cell.

The impulse begins when neurotransmitters from the association neuron change the porosity of the motor neuron’s membrane. This change results in depolarization.

The impulse spreads down a myelinated axon as the depolarization hops from one node of Ranvier to the next. The impulse shown has gone nearly halfway down the axon.

Chemical transmitters are released by specialized structures when the impulse gets to the neuron’s end. These chemicals stimulate the effector, in this case a muscle.
tion potential. Not every impulse that reaches a synapse is transmitted to the next neuron. The synapses thus help regulate and route the constant flow of nerve impulses throughout the nervous system.

**Disorders of the nervous system**

The nervous system can be damaged by injury and disease. Axons in the central nervous system cannot regrow after being damaged, but nerves in the peripheral nervous system may recover. Severely damaged nerve cells that die cannot be replaced.

Most neurons that perform a specific job are grouped together in the brain. Because of this grouping arrangement, called localization of function, damage to one area of the brain may affect only certain abilities and leave others intact. In some cases, undamaged areas of the brain gradually assume control of functions lost when another area of the brain was damaged. This action is called recovery of function.

The most common serious disorder of the nervous system is stroke. A stroke occurs if the blood supply to a certain area of the brain is cut off, resulting in the death of nerve cells. Stroke victims may lose the ability to perform functions controlled by the damaged area of the brain, such as speaking or moving a limb. Stroke victims may eventually recover some lost functions. But if respiration or some other vital function is affected, a stroke can be fatal.

The most common infectious diseases that affect the nervous system are mild virus infections that last only a few days and may produce headaches. More serious infectious diseases, such as encephalitis and meningitis, are caused by certain bacteria, viruses, or other microbes. Encephalitis is an inflammation of the brain, and meningitis is an inflammation of the membranes covering the brain and the spinal cord. See Encephalitis; Meningitis.

The cause of multiple sclerosis, a disease of the nervous system, is not known. Multiple sclerosis causes axons in various areas of the central nervous system to lose their myelin sheaths. As a result, these axons cannot conduct nerve impulses properly.

Another disorder of the nervous system is epilepsy. Victims of epilepsy suffer seizures that can cause muscle convulsions and a change in, or loss of, consciousness. An epileptic seizure occurs if most of the neurons in one area of the brain produce bursts of impulses at the same time. Physicians prescribe drugs to reduce the number of seizures or to prevent seizures from occurring at all.

Before the development of vaccines to prevent poliomyelitis, this virus disease of the nervous system was widespread. The polio virus can destroy motor neurons in the spinal cord and brain stem, leading to paralysis in some cases.

Some disorders of the nervous system can lead to mental illness or mental retardation. For information about these conditions, see the articles on Mental illness and Mental retardation.

**The nervous system in other animals**

In vertebrates. All vertebrates, including other mammals, as well as amphibians, birds, fish, and reptiles, have nervous systems much like the human nervous system. The neurons that make up the nervous systems of these animals are about the same size and shape as human neurons.

The size of a specific area of the brain may indicate the importance of the function of that area for the animal. For example, dogs have a larger and better developed area for smell than do human beings. In contrast, human beings have a larger and more highly developed cerebral cortex than other animals. The cerebral cortex is the outer surface of the cerebrum, where such complicated skills as delicate motor control and the use of language are coordinated.

In invertebrates. Most species of invertebrates that consist of more than one cell have some sort of nervous system. Many of the neurons of these animals are larger than human neurons. In hydras and some other simple invertebrates, the nervous system may be a nerve net, in which nerve cells are spread throughout the organism. There is no distinction between axons and dendrites in nerve net systems, and impulses travel in all directions from the point of stimulation.

Other invertebrates, including worms and insects, have more complicated, centralized nervous systems. These systems consist largely of concentrations of neurons that form a nerve cord. Ganglia along the cord serve as centers for organizing and integrating various activities of the animals. Clusters of ganglia in the front end of the body act as a primitive "brain." Many insects also have such ganglia in the thorax region. These ganglia coordinate motor activities. The mechanisms of nerve impulses and synaptic potentials in higher invertebrates are the same as those in the human nervous system.

**Additional resources**

**Ness, Eliot** (1903-1957), was an American crime fighter. He became known during the late 1920's and early 1930's as a special agent in the Prohibition Bureau of the United States Department of Justice. Ness led a group of law enforcement officers against Chicago gangster Al Capone and his bootlegging activities. Ness's group earned the nickname "the Untouchables" because, unlike many other public officials of the time, they could not be bribed or frightened by mobsters.

Ness was born in Chicago. He graduated from the University of Chicago in 1925. He joined the Justice Department as a special agent in 1928 and soon was appointed to lead an elite squad created to enforce the prohibition law. For more than two years, Ness and his
team of about 10 Untouchables raided Capone’s bootlegging operations. Ness’s squad seized barrels of illegal liquor, and beer delivery trucks, stills, and other equipment.

From 1935 to 1942, Ness acted as director of public safety in Cleveland, where he cleaned up corruption in the city’s police force. From 1942 to 1945, during World War II, he was director of the federal Social Protection Program, which was set up to handle certain public health issues on military bases. In 1945, Ness became a business executive. In 1947, he ran for mayor of Cleveland but was defeated.

**Ness, Loch.** See Loch Ness monster.

**Nest** is a place an animal prepares for raising its young. See Animal (Animal homes and communities); Ant (Nests); Bee (The honey bee colony); Bird (Building a nest); Hornet; Squirrel (Obtaining shelter); Wasp.

**Nestor.** See Messenia.

**Net** is an open fabric. It is produced by knotting or looping together yarns, cords, wires, or other materials so that there are spaces left between the points where the material intersects. Most nets are made of cotton, nylon, or polyester, but some nets are made of silk.

There are many kinds of nets, and they have a wide variety of uses. Such household items as curtains, hammocks, tablecloths, and bedspreads are made of net. Many sports, including tennis, volleyball, basketball, hockey, and soccer, feature nets. A type of light, fine net called tulle is used in ballet costumes and in veils.

Cargo is often loaded onto ships by means of heavy nets. Heavy nets also play an important role in the fishing industry. Some fishing nets weigh 10,000 pounds (4,500 kilograms) and are 2,000 feet (600 meters) long.

Nets were first made about 13,000 years ago. In the mid-1700’s, nets were produced on warp-knitting machines. These devices knit lengthwise stitches and create a flat fabric. Today, most nets are made on bobbinet machines or raschel knitting machines.

See also Fishing industry (How fish are caught); Lace.

**Netanyahu, neh tahn YAH hoo, Benjamin** (1949- ), a Likud Party politician, was prime minister of Israel from 1996 to 1999. That year, he was defeated in his bid for reelection by Ehud Barak, the leader of the Labor Party. After the election, Netanyahu resigned as Likud leader, a position he had held since 1993.

Netanyahu criticized the peace agreements between Israel and the Palestine Liberation Organization (PLO). These agreements, reached in the early and middle 1990’s, provide for Palestinian self-rule in the Gaza Strip and West Bank, territories Israel had occupied since 1967. Netanyahu claimed that the agreements did not include enough provisions for Israel, such as guaranteed security and allowance for its population growth.

Under Netanyahu, Israel’s peace negotiations with the PLO stalled. Netanyahu especially angered Palestinians with his decision to expand Israeli West Bank settlements and to build new Israeli housing in East Jerusalem.

Netanyahu, whose first name is sometimes spelled Binyamin, was born in Tel Aviv. He served in the Israel Defense Forces from 1967 to 1972. He then studied at the Massachusetts Institute of Technology, where he received a master’s degree in management in 1976. From 1984 to 1988, he was the Israeli ambassador to the United Nations. He was elected to the Knesset (Israeli parliament) in 1986 and served as deputy minister of foreign affairs from 1988 to 1991.
Amsterdam, the capital of the Netherlands, is crisscrossed by canals. Canals serve as waterways throughout the Netherlands and help drain the country's low-lying land.

Netherlands

Netherlands is a small country on the North Sea in northwestern Europe. It is bordered by Belgium and Germany. The Netherlands is often called Holland, but this name officially refers only to the western part of the country. The people of the Netherlands call themselves Nederlanders. They are also known as the Dutch.

"God created the world, but the Dutch created Holland," according to an old Dutch saying. More than two-fifths of the country's land was once covered by the sea, or by lakes or swamps. The Dutch "created" this land by pumping out the water. These drained areas, called polders, became some of the richest farmlands of the Netherlands.

To make a polder, the Dutch build a dike around the area to be drained of water. The water is then pumped into a series of drainage canals. Windmills were once used to run the pumps, but electric motors have replaced most of them. Most polders are below sea level, and they collect excess water through seepage. As a result, pumping must continue after the polders are built.

The Zuider Zee (pronounced ZY duhr ZAY), once a large inlet of the North Sea, was cut off from the sea in 1932 by a dike 20 miles (32 kilometers) long. This development changed the Zuider Zee into a freshwater lake called the IJsselmeer (EYE suhl meer). Much of the lake was then drained to make several large polders. This project added 637 square miles (1,650 square kilometers) of land for new farms and cities. The Netherlands gained an entire new province, Flevoland (FLEE voh lahn). The people of the Netherlands have great pride in their long battle against the sea. Because their country is one of the most densely populated countries in the world, they take extreme care to protect their hard-won land and to plan wisely the use of every acre. Several times during their history, however, the Dutch have opened the dikes and flooded the land to save their country from invaders.

Most of the Netherlands is flat, though it has some uplands. Many canals cut through the country. They not only drain the land but also serve as waterways.

Dairy farming is the most important form of agriculture in the Netherlands. The processing of dairy products is a major branch of Dutch manufacturing.

The country's rulers have included the Romans, a Germanic people called the Franks, the Spanish, and the French. The Dutch declared independence from Spain in 1581, and Spain recognized their independence in
1648. In 1815, the Netherlands became an independent kingdom united with Belgium. The two countries separated in 1830, when Belgium declared its independence.

The Dutch experienced a period of great prosperity and power—a Golden Age—during the 1600's. At that time, the country was the world's leading sea power, and it ruled a great colonial empire. Amsterdam was an important trading center, and Dutch businesses thrived. The Golden Age was also a time of cultural achievement, especially in painting.

Government

The Netherlands is a constitutional monarchy. It has a democratic government that is based on a constitution. Citizens aged 18 and older may vote.

National government. A king or queen is the country's head of state, but the monarch's duties are mostly ceremonial. The monarch signs all bills that are passed by the parliament and appoints government officials upon the advice of various government bodies.

Dutch monarchs, unlike those of other countries, are not crowned. Instead, they go through a ceremony called investiture, in which power is given to them by the people. This practice is based on a medieval tradition. In the Middle Ages, new leaders traveled from town to town in their realm. They asked for oaths of allegiance from local authorities and, in return, promised to respect the rights of the townspeople. The investiture takes place in Amsterdam, the official capital. Another city, The Hague (hayyay), is the seat of government.

A prime minister, appointed by the monarch, heads the government. The prime minister selects members of a Cabinet to run the government departments. If the Cabinet and the parliament cannot agree, either the Cabinet resigns, or the parliament is dissolved and a new election is held.

The parliament of the Netherlands, the States-General, consists of two houses. The First Chamber has 75 members, who are elected to four-year terms by the legislature of the country's provinces. The Second Chamber proposes new laws. It has 150 members, who are elected to four-year terms by the people. The members are chosen under a system called proportional representation. This system gives each political party a share of seats in the Second Chamber according to its share of the total votes cast.

Local government. The Netherlands is divided into 12 provinces, each governed by a commissioner and a council. The monarch appoints the commissioner. Council members are elected by the people to four-year terms. The number of council members varies according to population. The provinces are made up of municipalities. Each municipality has an elected council and an executive called a burgomaster, who is appointed by the monarch.

Politics. The largest political parties include two left-wing groups called Democrats 66 and the Labor Party, a centrist party called the Christian Democratic Appeal, and the right-wing People's Party for Freedom and Democracy (also called the Liberal Party). There are also many small parties. No party has held a majority of seats in the Second Chamber since 1945, when World War II ended. Therefore, all governments are formed by party coalitions (partnerships).

Courts. The court system in the Netherlands consists of subdistrict courts, district courts, courts of appeal, and the Supreme Court. The monarch appoints all judges.

Armed forces. The Netherlands has an army, a navy, and an air force. About 75,000 men and women serve in the country's armed forces.

The Kingdom of the Netherlands. The Netherlands is part of a larger political unit called the Kingdom of the Netherlands. The kingdom also includes the Netherlands Antilles—two groups of islands in the Caribbean Sea—and the island of Aruba, also in the Caribbean. Both the Netherlands Antilles and Aruba have an appointed governor and a Council of Ministers headed by a prime minister. Each Council of Ministers is responsible to a one-house legislature, whose members are elected by the islanders.

People

About 40 percent of the people of the Netherlands live in two coastal provinces—North Holland and South Holland. In these provinces are the three largest cities—Amsterdam, Rotterdam, and The Hague.

Ancestry. Most of the people in the Netherlands are of Dutch ancestry. The largest non-Dutch groups in the country include people from Indonesia, Morocco, Suriname, and Turkey.

Language. Dutch is the official language of the Netherlands. The Dutch language belongs to the Germanic language group. The people of the northern province of Friesland (FRAYZEL lahnt) speak Frisian (FRIHZHL uhn), another Germanic language. Most people of the Netherlands also speak English, and many speak French or German as well.

Way of life

The Netherlands is one of the most densely populated countries in the world. Nearly half of this small country lies below sea level, so the Dutch must carry on a continuous battle against the sea. Life in this environment has given the Dutch a practical, matter-of-fact outlook. To make the best use of their limited land and avoid overcrowding, the Dutch have developed a highly organized society. Neatness and self-control are prized. The Dutch tend to frown on extravagance and displays of wealth.

Although public life in the Netherlands is highly organized, there is a great deal of freedom in private life. The Dutch value personal privacy. They are also known for their good fellowship, called gezelligheid (guz ZEHHL ihk hvtl). This cozy friendliness among close friends and relatives is most frequently found at gatherings celebrating such occasions as birthdays and anniversaries. The Dutch are also interested in foreign countries, and many of them travel and work outside the Netherlands.

City life. For centuries, the Netherlands has been one of Europe's most urbanized regions. Nearly all Dutch cities were founded in the Middle Ages. The historic centers of these cities still have many shops and businesses and government offices. Public transportation is readily available, including subways and streetcars in the large cities.

Most city dwellers live in modern apartments and row houses. Because of high land prices, the cities have few single-family houses. The older residential sections of
Netherlands in brief

General information
Capital: Amsterdam.
Seat of government: The Hague.
Official language: Dutch.
Official name: Koninkrijk der Nederlanden (Kingdom of the Netherlands)
National anthem: "Wilhelmus van Nassouwe" ("William of Nassau").

Largest population centers: (1994 official estimates)
Cities
Amsterdam (724,096)  Rotterdam (598,521)  The Hague (445,279)  Utrecht (234,106)
Metropolitan areas
Amsterdam (1,100,120)  Rotterdam (1,074,387)  The Hague (695,217)  Utrecht (545,796)

The Dutch flag dates from about 1630. Until then, an orange stripe was at the top instead of a red one.
The coat of arms has old symbols of the Dutch royal family. The sword and arrows represent strength in unity.

Land and climate
Land: Netherlands is on the North Sea in northwestern Europe. It is bordered by Belgium and Germany. Most of the Netherlands is flat, though it has some uplands. Part of the country is made up of polders, land below sea level that was once covered by water. The Dutch built dikes around these areas and drained the water.

Area: 16,033 mi² (41,526 km²), including 2,929 mi² (7,587 km²) of inland water. Greatest distances—north-south, 196 mi (315 km); east-west, 167 mi (269 km). Coastline—228 mi (367 km).
Elevation: Highest—Vaaler Berg, 1,033 ft (312 m) above sea level. Lowest—Prins Alexander Polder, 22 ft (6.7 m) below sea level.

Climate: The Netherlands has a mild, damp climate, with moderately warm summers and gentle winters. Temperatures average from 60 to 65 °F (16 to 18 °C) in summer, and a little above 30 °F (−1 °C) in winter. Extremely hot or cold temperatures are rare. Summer is the wettest season, though precipitation is fairly evenly distributed throughout the year. Most regions of the country receive about 25 to 30 inches (63 to 76 centimeters) of precipitation a year.

Government
Form of government: Constitutional monarchy.
Ceremonial head of state: Monarch (king or queen).
Head of government: Prime minister.
Legislature: States-General of two houses: 75-member First Chamber and 150-member Second Chamber.
Executive: Prime minister and Cabinet.
Political subdivisions: 12 provinces.

People
Population density: 989 per mi² (382 per km²).
Distribution: 61 percent urban, 39 percent rural.
Major ethnic/national groups: Almost entirely Dutch. Largest non-Dutch groups include people from Indonesia, Morocco, Suriname, and Turkey.
Major religions: About 30 percent Roman Catholic, about 30 percent Protestant (mostly Dutch Reformed Church), small percentage Muslim. Nearly half of the Dutch are not members of any church.

Economy
Money: Basic unit—euro. One hundred cents equal one euro. The guilder was taken out of circulation in 2002.

Foreign trade: Major exported goods—automobiles, chemicals, dairy products, electric machinery, flowers, meat, petroleum, plastics, precision instruments, vegetables. Major imported goods—automobiles, chemicals, clothing, electric machinery, iron and steel, paper and paper products, petroleum, plastics, and precision instruments. Main trading partners—Belgium, France, Germany, Italy, Luxembourg, United Kingdom, United States.
the major cities house many immigrants as well as university students and young adults.

**Rural life.** Because every region of the Netherlands has several cities, few rural areas are truly remote. Farms are commercial businesses, and rural life is not too different from life in the towns. Most villages are accessible by water and are well provided with services and public transportation.

People in farm areas and fishing villages sometimes wear the famous Dutch wooden shoes, called klompen (KLAHM-uhn). These shoes are noisy, but they protect the feet from damp earth better than leather shoes do. The Dutch do not wear wooden shoes in their homes. They leave them outside and change to leather shoes.

In a few rural areas, the people still wear the traditional Dutch costume, which includes full trousers for men and full skirts and lace caps for women. These areas include the islands of the province of Zeeland (ZAY-lahn), coastal fishing communities, and the towns of Staphorst (STAHP havrsts) and Spakenburg (SPAHK kuhn burkh).

**Food and drink.** The Dutch diet is similar to that of other northern European countries. Breakfasts often consist of bread, cheese, and cold meat. Most people eat a light lunch of a sandwich or salad. Most dinners include meat or fish, potatoes, and vegetables. Indonesian food is also popular. Traditional dishes include hutspot (a stew of meat, vegetables, and potatoes, pronounced HUTS pahl); raw herring sprinkled with onions; and large, thin pancakes covered with toppings. Beer and jenever (juniper-flavored gin, pronounced yuh NAY fur) are popular alcoholic drinks.

**Holidays and recreation.** Most people in the Netherlands own a bicycle, and bicycle riding is a popular recreational activity. The Dutch also enjoy boating, sailing, and windsurfing on their many lakes, rivers, and canals. Miles of sandy beaches along the North Sea coast provide many places to swim.

Ice skating is extremely popular. But the Netherlands has mild winters, and the ice often does not get thick enough for skating. When the ice is hard enough, schools sometimes close to let the children skate. In exceptionally cold winters, an ice-skating race called the Elfstedentocht (ehlf STEHLD uhn takht) takes place on the waterways of Friesland. The 124-mile (200-kilometer) course connects 11 cities of the northern province.

Every community has sport clubs that organize team sports for youths and adults. The most popular sports include field hockey, soccer, and tennis.

The people of the Netherlands are famous for raising tulips and other flowers, and they hold many spectacular flower festivals each spring. Long parades of floats covered with blue, pink, red, and yellow blossoms wind through the towns near the bulb fields. Homes along the way are also decorated with beautiful floral designs.

The Dutch celebrate Queen’s Day, the birthday of former Queen Juliana, on April 30 with local parades, games, and flea markets. Most towns hold a fair called a kermis (KEHR mihs) with carnival attractions and other entertainment.

The Dutch exchange gifts on St. Nicholas’s Eve, December 5, instead of on Christmas. The children believe that Saint Nicholas visits their homes with presents for

**Bicycle riders** cross an intersection in Gouda, above. Bicycling is popular among Dutch people of all ages, both as a recreational activity and as an important means of transportation.

A Queen’s Day celebration, held annually on April 30, includes a variety of entertainment. Above, people gather for festivities at a World War II monument in Amsterdam’s Dam Square.
good boys and girls. A man dressed like a bishop represents a Saint Nicholas and rides through the streets on a white horse. In Amsterdam, he arrives by steamship and is greeted by ringing bells and cheering crowds.

During the 1600's, the Dutch brought the custom of Saint Nicholas's visit with them to America. There, the English settlers changed his Dutch nickname, Sinterklaas, to Santa Claus.

Religion. Roman Catholics and Protestants each make up about 30 percent of the Dutch population. The Netherlands also has a small number of Muslims. Nearly half of the Dutch are not members of any church. The majority of Protestants belong to the Dutch Reformed Church. Members of the royal family traditionally belong to this church, but it is not an official state church.

Education. Dutch law requires children from ages 5 through 16 to go to school. All schools that meet national educational standards, including religious schools, receive government funds. The standards, set by law, include courses of study and hiring of teachers. Almost all adults can read and write. For the country's literacy rate, see Literacy (table: Literacy rates for selected countries).

The Netherlands has no general high school program. Instead, it has several kinds of high schools. Each kind trains students for a special purpose, such as university work, advanced study in various institutes, or jobs in business or industry.

The Open University, based in Heerlen, has the most students of any Dutch university. Instruction is carried out through correspondence. In addition, the Netherlands has 13 traditional universities and many specialized institutions for higher education. The University of Amsterdam is the largest traditional university. Leiden University, founded in 1575, is the oldest university.

Arts. The Netherlands has produced some of the world's greatest painters. During the 1600's, the country's Golden Age, the northern Netherlands was a republic. Without a royal court to order works of art, Dutch artists had to sell their creations to the country's prosperous bankers, merchants, and traders. Dutch buyers looked for small paintings suitable for private homes, rather than large-scale religious works, so Dutch artists often painted ordinary people and things. Frans Hals became a master painter of portraits. Pieter de Hooch (Pee'r duh HOHN) and Jan Vermeer (vahn vyur MEER) often painted indoor scenes, and Jacob van Ruisdael (vahn ROYSS duhl) specialized in landscapes. Rembrandt painted masterpieces on many subjects.

Later Dutch painters include Vincent van Gogh and Piet Mondrian. Van Gogh, who painted in the late 1800's, is one of the most famous painters in modern art. Mondrian, who developed his extremely simplified geometric style of painting in the early 1900's, influenced modern architecture and commercial design as well as painting. Many museums in the Netherlands exhibit the works of the great Dutch artists. Among them are the Rijksmuseum and Stedelijk Museum in Amsterdam and the Gemeentemuseum in The Hague.

The Dutch enjoy reading and support many writers. But Dutch literature is little known outside the Netherlands, and few works have been translated. One of the most important Dutch writers is Joost van den Vondel (YOHST vahn dehn VAHN duhl), a celebrated poet and playwright of the Golden Age. Constantijn Hyggen

(KAHN stuh n yeu HY gwuhnz), another figure of the Golden Age, produced witty, elegant verse.

Other important writers include Willem Bilderdijk (VIHL uhm PY duhrt DAK), Multatuli (muht tah TOO lee), and Louis Couperus (loo EE koo PAY ruhr). Bilderdijk, a poet of the late 1700's and early 1800's, foreshadowed the Romantic era. Multatuli, the pen name of Eduard Douwes Dekker, was the author of Max Havelaar (1860), a novel about life in the Dutch East Indies that exposed the corruption and misrule there. Couperus, who wrote in the late 1800's and early 1900's, was acclaimed for his psychological novels.

Among the better-known Dutch composers are organist Jan Pieterszoon Sweelinck (yahn PEE tuh SOHN SVAY leehngk), who achieved renown at the beginning of the 1600's for his organ compositions, and Willem Pijper (VIHL uhm PY puhr), a leading composer in the first half of the 1900's. Several Dutch cities have fine symphony orchestras. The Concertgebouw (kahn SAIRT guh bow) Orchestra of Amsterdam is world famous.

The land

The Netherlands has four main land regions: (1) the Dunes, (2) the Polders, (3) the Sand Plains, and (4) the Southern Uplands.

The Dunes are high, sandy ridges where tall grasses often grow. This region curves in a line along the entire North Sea coast of the Netherlands. In the north, the line consists of the West Frisian Islands. The line is unbroken in the center, but it is broken in the south by wide river outlets.

The Polders lie mostly below sea level and are protected from the sea by the sand dunes or by dikes. The Prins Alexander Polder, the lowest point in the Netherlands, is near Rotterdam. It lies 22 feet (6.7 meters) below sea level. The Polders region forms over two-fifths of the country. It consists of flat, fertile areas of clay soils that were once covered by seas, swamps, or lakes. It has some of the country's most productive farmlands and largest cities.

Much of the southern part of the Polders consists of marshy islands and peninsulas that make up a delta. The delta is formed by the Maas (mahs) and Schelde (SKEHL duh) rivers and branches of the Rhine River. Massive dams prevent the sea from flooding the region. One of the dams has huge floodgates that allow salt water and natural tides to enter the protected area. This preserves the natural environment and the fishing economy of the region. During storms, the floodgates can be closed.

The Sand Plains lie less than 100 feet (30 meters) above sea level in most places. In the southwest, the re-

In the Rijksmuseum in Amsterdam, visitors admire Rembrandt's famous painting The Night Watch. The Netherlands has many museums that exhibit masterpieces of Dutch art. The country has produced some of the world's greatest painters.
The Netherlands has a mild, damp climate. It has gentle winters and moderately warm summers. The sky is frequently overcast in winter, and fog often covers the land. Temperatures average from 60 to 65 °F (16 to 18 °C) in summer, and a little above 30 °F (−1 °C) in winter. Extremely hot or cold temperatures are rare. The Netherlands is small in area, and there are no great differences of climate from region to region. Most areas of the country receive about 25 to 30 inches (63 to 76 centimeters) of precipitation (rain, melted snow, and other forms of moisture) in a year. Summer is the wettest season, but precipitation is fairly evenly distributed throughout the year. The Dutch weather is changeable, and showers may fall unexpectedly. Floods threaten the Netherlands from two directions. North Sea storms pound against the coastal dunes and sea dikes. Rain-swollen rivers, especially the Maas and the Rhine, press against the river dikes. Dike breaks in the past have resulted in many floods, sometimes with great loss of life. For example, a massive flood along the North Sea coast in 1953 caused about 1,800 deaths. The country is so low-lying that it would be flooded if global warming melted polar ice and raised the sea level.

Economy

The economy of the Netherlands is technically advanced and highly industrialized. Because the country has few natural resources, it depends heavily on foreign trade. Industries import most raw materials and export finished products. Modern farming techniques have made the small amount of farmland highly productive.

Service industries, taken together, account for over two-thirds of the gross domestic product (GDP)—the total value of goods and services produced within the
country in a year. Over 70 percent of all workers are employed by service industries. Finance, insurance, real estate, and business services make up the leading service industry. These services provide about a fourth of the country's GDP—more than any other industry. Trade, restaurants, hotels, and repair shops form the second most important service industry.

Manufacturing accounts for about a sixth of the GDP. Several large international manufacturers have headquarters in the Netherlands. For example, Eindhoven (EYENT hoov vahn) is the headquarters of Philips Electronics, one of the world's largest electronics firms. The company produces household appliances, consumer electronics, and semiconductors. Other manufacturers produce automobiles and trucks, small commercial airplanes, and industrial machinery.

Food processing is a major manufacturing industry. Dairy products are the chief food products. The Netherlands is one of the world's major cheese manufacturers. Other Dutch food products include beer, chocolate, processed meats, and sugar.

The chemical industry produces drugs, paints, plastics, and synthetic rubber. Rotterdam is the site of a huge complex of oil refineries and chemical plants. Amsterdam has long been a famous center of diamond cutting and polishing. Delft is known for producing earthenware pottery called Delftware.

Agriculture. Because land is scarce, Dutch farmers work to make their soil as productive as possible. The farms average only 36 acres (15 hectares). But by fertilizing the soil heavily and using modern equipment, Dutch farmers have become specialized producers of products sold throughout the world. The value of agricultural exports is larger than the value of agricultural imports.

About two-thirds of the country's total land area is farmland. Just over half of the farmland is used for grazing, and the rest is used to grow crops. Dairy farming is the most important branch of agriculture. Most dairy

Economy of the Netherlands

This map shows the economic uses of land in the Netherlands. It also indicates the country's main farm products, its chief mineral deposits, and its most important fishing products. Major manufacturing centers are shown in red.
Dairy cows are a familiar sight in the Netherlands. Dairy farming is the country's most important branch of agriculture. Modern windmills stand in the grazing land pictured above.

farmers also raise crops, mainly to feed their livestock. The grazing land supports about 4 ½ million cattle, chiefly dairy cows. Dutch farmers also raise beef cattle, hogs, poultry, and sheep.

The country's principal crops include barley, potatoes, sugar beets, and wheat. An important specialty of Dutch agriculture is horticulture. Flowers and vegetables are grown in enormous greenhouses. They are trucked to neighboring countries, and fresh flowers are flown to most parts of the world. Flower bulbs, especially tulip bulbs, are also important.

Mining. The Netherlands has large deposits of natural gas and salt, and some petroleum. One of the world's largest natural gas fields lies near Slochteren (SLAHK tuh ruhn), in the northeastern province of Groningen (GROH nihng uhn). Oil wells operate offshore in the North Sea.

Fishing. The fish catch comes mainly from coastal waters and inlets, and from the North Sea. Coastal waters provide eels, mussels, and shrimp. The major sea catches are herring, mackerel, plaice, and sole.

Energy sources. The Netherlands is a major producer of natural gas. But its oil wells supply only a small part of its petroleum needs. Natural gas provides most of the country's energy, and petroleum, coal, and nuclear power provide the rest.

International trade. The Netherlands relies heavily on foreign trade because it has few natural resources. Its chief trading partner is Germany. Other important trading partners are Belgium, France, Italy, Luxembourg, the United Kingdom, and the United States.

The main imports of the Netherlands include automobiles, chemicals, clothing, electric machinery, iron and steel, paper and paper products, petroleum, plastics, and precision instruments. Among the exports are automobiles, chemicals, dairy products, electric machinery, flowers, meat, petroleum, plastics, precision instruments, and vegetables.

Transportation. The Netherlands has an extensive network of navigable rivers and canals. The main rivers and many of the canals are important waterways. Barges on these waterways carry a great deal of the country's freight. The country's railroad system provides fast and frequent service.

The Netherlands has an excellent network of paved roads. Almost all Dutch families own an automobile, and most people have a bicycle. The bicycle remains important for transportation as well as recreation. Bike paths are found throughout the country. Motor-driven bicycles called bromfietsen (pronounced BRAHM feet suhn), which literally means roar bikes, are common.

Rotterdam is the busiest seaport in the world. It serves as a gateway to and from much of Europe by way of the Rhine River, one of Europe's busiest inland waterways. Amsterdam, the second largest port in the Netherlands, is linked to the North Sea by the North Sea Canal, one of the world's deepest and widest artificial waterways. The
canal is about 50 feet (15 meters) deep and 525 feet (160 meters) wide.

The country’s most important airport, Schiphol (SKHP hohl), near Amsterdam, is one of the busiest airports in Europe. Royal Dutch Airlines (KLM) has headquarters there. Established in 1919, KLM is the oldest airline in the world still in operation.

**Communication.** The Netherlands has about 45 daily newspapers. The largest is *De Telegraaf*, published in Amsterdam and sold throughout the country.

Traditionally, private broadcasting companies have prepared most programs for the radio and television networks. Most of these companies represent political, religious, or cultural groups. In the late 1900’s, commercial broadcasting emerged to supplement the traditional private programming. In addition, cable television opened the country to a wide variety of foreign and commercial programs. Postal and telephone services are provided by a private firm.

**History**

**Early days.** In the 50’s B.C., Roman soldiers under Julius Caesar invaded what are now the Netherlands, Belgium, and Luxembourg. The Romans conquered much of the region, now called the Low Countries. The word *Netherlands* means Low Countries, but the Low Countries also include Belgium and Luxembourg.

In the A.D. 400’s, a Germanic people called the Franks drove the Romans out of the Low Countries. The Frankish kingdom broke apart during the 800’s. In 870, the Low Countries were divided between the East and West Frankish kingdoms (later Germany and France). The area that is now the Netherlands became part of the East Frankish kingdom.

**The rise of commerce.** Local dukes, counts, and bishops became increasingly powerful as the region developed. During the 1100’s, trade and industry began to expand rapidly in the Low Countries. Fishing, shipbuilding, shipping, and textile manufacturing became especially important. Towns began to develop and grow.

**Spanish control.** Beginning in the 1300’s, the French dukes of Burgundy won control of most of the Low Countries through inheritance, marriage, purchase, and war. The marriage of Mary of Burgundy to Maximilian of the House of Habsburg in 1477 joined the Low Countries with the Habsburg empire. In 1516, Mary and Maximilian’s grandson Charles inherited the kingdom of Spain, putting the Low Countries under Spanish control. In 1519, Charles also became Archduke of Austria and Holy Roman Emperor Charles V.

**Freedom from Spain.** During the early 1500’s, a Protestant movement called the Reformation spread through the Low Countries. Charles tried to stop this threat to Roman Catholicism by persecuting Protestants. Charles gave up rule of the Low Countries and of Spain, in 1555 and 1556, to his son, Philip II. Philip stepped up the struggle against Protestants and tried to take complete power over the Low Countries. In 1566, the people began to rebel. In 1568, William I (called the Silent), prince of Orange, led the nobles in revolt.

The Spanish troops were generally successful in land battles, but the rebels’ ships controlled the sea. The Spaniards attacked Leiden in 1573, but the city held out bravely. In 1574, the people opened dikes that held back the sea, and a Dutch fleet sailed over the floodwaters to rescue Leiden from the Spaniards.

By 1579, the revolt had started to break apart. The southern provinces of the Low Countries (now Belgium) returned to Spanish control. Protestantism became stronger in the northern provinces (now the Netherlands). In 1579, most northern provinces formed the Union of Utrecht and pledged to continue the revolt.

On July 26, 1581, the northern provinces declared their independence from Spain, beginning what later became known as the Dutch Republic or the Netherlands. The Dutch fought for their freedom until 1648, except for a temporary peace from 1609 to 1621. Spain finally recognized Dutch independence in 1648.

**Prosperity and power.** The 1600’s were the Golden Age of the Netherlands. The country became the leading sea power. Its merchant fleet tripled in size between 1600 and 1650, and the Dutch accounted for about half of Europe’s shipping. Dutch explorers, including Willem Barents (*VIHLuhn BAHR uhn*) and Abel Janszoon Tasman (*AH buhl YAHN sohn TAZ muhn*), found new sea routes and fisheries. Amsterdam became a great trading center of Europe. Dutch banks and businesses thrived. The Golden Age also brought major cultural achievements, especially in painting.

During the Golden Age, the Dutch Republic developed a great colonial empire in many parts of the world. In 1602, Dutch firms trading with the East Indies combined to form the Dutch East India Company. The company founded Batavia (now Jakarta, the capital of Indonesia) as its headquarters. The company’s forces

**Important dates in the Netherlands**

1500’s B.C. Julius Caesar conquered much of the Low Countries, including what is now the Netherlands.

A.D. 400’s The Franks controlled the region.

1100’s The Netherlands became part of the East Frankish kingdom (now Germany).

1300’s The French dukes of Burgundy united most of the Low Countries.

1516 Charles, ruler of the Low Countries, became King Charles I of Spain. In 1519, Charles became Holy Roman Emperor Charles V.

1581 The Dutch declared their independence from Spain.

1648 Spain recognized Dutch independence.

1600’s The Netherlands became the world’s major sea power and developed a great colonial empire.

1795-1813 France controlled the Netherlands.

1815 The Netherlands became an independent kingdom united with Belgium.

1830 Belgium revolted and became independent.

1840-1945 Germany occupied the Netherlands in World War II.

1849 The Netherlands granted independence to the Netherlands Indies (now Indonesia).

1954 The colonies of Suriname and Netherlands Antilles became equal partners in the Dutch kingdom.

1957 The Netherlands helped form the European Economic Community, a forerunner of the European Union (EU).

1962 The Netherlands gave up control of West New Guinea (now Irian Jaya) to the United Nations.

1975 Suriname became a fully independent nation.

1992 The Netherlands and 11 other European nations signed the Treaty of European Union, an agreement establishing the EU, in the Dutch city of Maastricht.
The Golden Age of the Netherlands was the 1600's. During this period, the country became a leading sea power, and it developed an extensive colonial empire. Ships bringing goods to and from Amsterdam, above, made the city one of the greatest trading centers of Europe.

largely drove the British and Portuguese out of what later became the Netherlands Indies (now Indonesia). The company also took control of Ceylon (now Sri Lanka) and colonized the southern tip of Africa. From the mid-1600's to the mid-1800's, the Dutch were the only Westerners allowed to trade with Japan.

The Dutch West India Company was founded in 1621 to trade in the New World and western Africa. In 1624, the company colonized New Netherland, which consisted of parts of present-day New York, New Jersey, Connecticut, and Delaware. In 1626, the colony's governor, Peter Minuit, bought Manhattan Island from the Indians for goods worth about $24. Dutch colonists had established New Amsterdam (now New York City) there the year before. From 1630 to 1654, the Dutch controlled Brazil. During that time, the Dutch also acquired what are now the Netherlands Antilles and Aruba.

Wars with England and France. The Netherlands fought three naval wars with England from 1652 to 1674. The English hoped to seize the shipping and trading leadership from the Dutch, but they failed. During this period, the Dutch won what is now Suriname from the English, and the English gained New Netherland.

France and England formed a secret alliance against the Dutch Republic in 1670 and attacked it in 1672. The Dutch fleet prevented the English from landing by sea, but French troops seized a number of Dutch towns. William III, prince of Orange, was then elected stadholder (governor). He stopped the French by opening some dikes and flooding the land. Spanish and German troops also helped the Dutch. The English suffered major defeats at sea, and they made peace with the Dutch in 1674. The French were driven out, and they signed a peace treaty in 1678.

William's wife, Mary, was a member of the English royal family. In 1689, William led what is called the Glorious Revolution and became King William III of England as well as the Dutch stadholder. The Netherlands, England, and other European countries battled France in two more wars, fought from 1689 to 1697 and from 1701 to 1714.

The 1700's. The long wars against France exhausted the Netherlands. Dutch industry and trade began to falter, and the Netherlands entered a period of economic decline.

During the Revolutionary War in America (1775-1783), the Dutch aided the Americans against the British. Britain started a naval war against the Dutch in 1780. The Dutch were severely defeated by 1784.

In 1795, the weakened Netherlands fell to invading French troops. The Dutch supporters of the French renamed the country the Batavian Republic and set up a new government. Britain seized most of the Dutch overseas possessions.

Independence. In 1806, Napoleon I of France forced the Dutch to accept his brother Louis as their king. The Batavian Republic became the Kingdom of Holland. Napoleon wanted tighter control over the country and made it part of France in 1810. The Dutch drove out the French in 1813.

In 1814 and 1815, Europe's political leaders remapped much of the continent at a series of meetings called the Congress of Vienna. They united Belgium, Holland, and Luxembourg into the Kingdom of the Netherlands to limit the power of France. William VI, prince of Orange, became King William I of the Netherlands and Grand Duke of Luxembourg.

The customs, economies, languages, and religions of the Dutch and the Belgians differed greatly. The majority of Belgians were Roman Catholics, and the upper classes spoke French. In 1830, Belgium declared its independence from the Kingdom of the Netherlands.

Luxembourg ended its political ties with the Dutch royal family in 1890. That year, 10-year-old Wilhelmina had become queen after the death of her father, William III. But Luxembourg's laws did not permit a female ruler.

The Netherlands stayed neutral during World War I (1914-1918). But the naval operations of the warring countries interfered with Dutch shipping and trading.

World War II. On May 10, 1940, during World War II, German troops invaded the Netherlands. Four days later, German bombers destroyed much of Rotterdam. The
After World War II, much of the Netherlands lay in ruins. For example, central Rotterdam, shown here, was destroyed, and its great port was crippled. The Dutch quickly rebuilt their country.

Dutch army surrendered. Most of the Dutch navy escaped capture and supported the Allies, the countries opposing Germany and its partners.

During the German occupation, from 1940 to 1945, the Dutch suffered greatly. The Germans killed about 75 percent of the nation’s Jews—about 104,000 people—mostly in death camps. They also forced thousands of other Netherlands to work in German factories. The Dutch resistance movement secretly published newspapers, hid Jews from capture, and committed acts of sabotage against the Germans. By the time Germany surrendered to the Allies in May 1945, about 250,000 Netherlands had been killed or had starved to death.

The Netherlands was also involved in the war in the Pacific Ocean. In March 1942, the Netherlands Indies (now Indonesia) fell to Germany’s ally Japan after the defeat of the Dutch fleet. The tens of thousands of Dutch then residing in the Indies became prisoners in Japanese camps.

Economic recovery. World War II left much of the Netherlands in ruins. Many of the nation’s factories, bridges, and railroad lines had been destroyed. The great harbor at Rotterdam was crippled. Much of the land was flooded as a result of damage to the dikes.

After the war, the Dutch dedicated themselves to rebuilding their country, and the government supported close international cooperation to achieve this goal. In 1945, the Netherlands became a charter member of the United Nations (UN). In 1948, the Netherlands joined with Belgium and Luxembourg to eliminate all tariffs on trade among themselves, forming an organization called Benelux. In 1949, the Netherlands became part of the North Atlantic Treaty Organization (NATO), a defense alliance of European and North American nations.

In the 1950’s, the Netherlands helped form the European Coal and Steel Community, the European Atomic Energy Community (Euratom), and the European Economic Community. These agencies later became the basis for the European Union, which works for economic and political cooperation among its members.

By 1955, Dutch industrial production had increased about 60 percent over the pre-World War II level. Farm output was almost 20 percent greater.

Political changes. In 1948, the aging Queen Wilhelmina gave up the throne to her daughter, Juliana. At that time, a revolt was underway in the Netherlands Indies. The fighting, which had started in 1945, continued until 1949, when the Netherlands recognized Indonesia’s independence. In 1954, Suriname and the Netherlands Antilles—which then included the island of Aruba—were made self-governing and equal members of the Dutch kingdom. In 1962, the Dutch gave up West New Guinea (now Irian Jaya), their last colony, to UN control. The UN turned over Irian Jaya to Indonesia in 1963.

In 1980, Juliana gave up the throne at the age of 71. Her oldest daughter, Beatrix, became queen.

Economic development. By the late 1900’s, the Netherlands had achieved a high standard of living. Economic cooperation, both with other countries and at home, helped the Dutch to reestablish much of their prosperity after World War II. During the late 1940’s and the 1950’s, Dutch industry, labor, and government worked together to avoid strikes and expand industry. The discovery of a natural gas field in the northern part of the country in 1939 also provided the Netherlands with a great economic boost. And Rotterdam, heavily damaged during the war, was rebuilt.

Diversity. Hundreds of thousands of people from former Dutch colonies and from Mediterranean countries have moved to the Netherlands. This immigration has added diversity to the country’s population. Many of the immigrants came from Indonesia. In the 1970’s, people from the Molucca Islands demanded that the Dutch government take steps to free their homeland from Indonesian control. Some Moluccans in the Netherlands staged terrorist acts to dramatize their demands.

In 1975, Suriname left the Kingdom of the Netherlands and became a fully independent nation. Many people from Suriname moved to the Netherlands shortly before independence. In the late 1900’s, many Turks and Moroccans settled in the Netherlands. Refugees from many countries also came to the Netherlands because of its liberal laws granting political asylum (shelter and protection) to people fleeing other nations.

Recent developments. In 1992, the Netherlands was 1 of 12 countries that signed the Treaty on European Union, also called the Maastricht Treaty for the Dutch city where it was signed. This treaty provided for the formation of the European Union. The treaty also called for a single European currency, known as the euro. In 1999, the Netherlands and most other European Union countries officially adopted the euro. Euro notes and coins replaced the notes and coins of the traditional Dutch currency, the gulder, in 2002.

**Nettle**

**Nettles**

**Nettle, 151**

**Netherlands Antilles, an**

*Nettle* (Urtica dioica) is also called the Dutch West Indies, consists of two groups of islands in the Caribbean Sea. One group lies about 50 miles (80 kilometers) from Venezuela. The smaller group is about 500 miles (800 kilometers) northeast of the main islands and about 160 miles (257 kilometers) east of Puerto Rico.

The islands have a total area of 308 square miles (798 square kilometers) and a population of about 221,000. The southern group, made up of Bonaire and Curaçao, covers 266 square miles (689 square kilometers) and has about nine-tenths of the population. Curaçao, which covers 171 square miles (444 square kilometers), is the largest island in either group. Willemstad, capital of the Netherlands Antilles, is on Curaçao. The northern group includes Saba and St. Eustatius islands, and the southern part of St. Martin (also spelled St. Maarten) Island. These islands cover only 26 square miles (68 square kilometers). See Curaçao; Willemstad.

Oil refining and tourism are the major industries in the Netherlands Antilles. Crude oil is shipped to refineries on Curaçao from Venezuela. Tourism is the chief industry of the other islands. The land and climate of the islands make farming difficult. Most of the food must be imported. The people on Curaçao speak Dutch, English, Spanish, and a mixture of the three languages called *Papiamento*.

The Netherlands Antilles is an equal partner with the Netherlands in the Kingdom of the Netherlands. The islands are self-governing. The governor is appointed by the Dutch monarch.

The Spanish first occupied Curaçao in 1527. The Dutch captured the Antilles area between 1630 and 1654, the period that they controlled Brazil. The island of Aruba was formerly part of the Netherlands Antilles. It split from them in 1986 (see Aruba).

**Nettles** are the common name of a group of plants with stinging bristles. Nettles are coarse herbs that grow as weeds in North America, Europe, and Asia. They have leaves that grow opposite one another on the stem, and tiny flower clusters. Nettle bristles contain a watery juice that produces an intense itch when it enters a person's skin. This itch does not last long. The bristles usually have no effect in places where the skin is thick.

Young shoots of nettle plants can be cooked like spinach and are a good source of vitamins and protein. People have used nettles for medicinal purposes since ancient times. The *stinging nettle* of Europe and the United States has been cultivated for its fiber, from which a strong, coarse cloth can be made.

Ronald L. Jones

**Scientific classification**

Nettles belong to the nettle family, Urticaceae. They make up the genus *Urtica*. The stinging nettle is *U. dioica*.

See also Boehmeria; Ramie.
Netzahualcóyotl, *NAY tsah wahl KOH yoht uhl* (pop. 1,224,924), is the third largest city in Mexico. Only Mexico City and Guadalajara have more people. Netzahualcóyotl is located in the state of México and borders Mexico City on the east. For location, see Mexico (political map).

Netzahualcóyotl was founded in 1900 as a suburb of Mexico City. It was not incorporated as a city until 1963. Since 1970, Netzahualcóyotl's population has more than doubled. The city's rapid growth has produced problems, including a shortage of good housing, a lack of basic city services, and pollution. The city is largely populated by working-class people. A number of manufacturing plants operate there.

**Neumann, Saint John Nepomucene** (1811-1860), was the first male United States citizen to be recognized as a saint by the Roman Catholic Church. He was canonized/declared a saint in 1977.

Neumann was the bishop of Philadelphia from 1852 until his death. As bishop, he increased the number of Catholic elementary schools in the city from 2 to almost 100. He helped bring several sisterhoods from Europe to run the schools.

Neumann was born on March 28, 1811, in Prachatitz, Bohemia. He came to the United States in 1836 and was ordained later that same year. In 1840, he joined the Redemptorist Fathers, a society of missionary priests. Neumann became a U.S. citizen in 1848.

**Neuralgia, nu RAL juh** is a severe pain that occurs along a nerve. Its cause is not known. The pain may be limited to one part of the nerve, or it may extend along the nerve's branches. It may occur as repeated stabs of pain in the teeth, sinuses, eyes, face, tongue, or throat.

Neuralgia occurs most frequently in two cranial nerves. One nerve, the *trigeminal*, has three branches that enter the eyes, face, sinuses, and teeth. The other, the *glossopharyngeal*, leads to the back of the tongue and throat. Neuralgia is sometimes confused with other conditions called *neuritis* and *radiculopathy*. But these occur in many different parts of the body. True neuritis is an inflammation that can permanently damage a nerve. Neuralgia does not harm the nerve.

**Tic douloureux** is a type of neuralgia that is common among older people. The name is French for painful twitching. Tic douloureux affects the trigeminal nerve and causes facial pain. The face muscles may contract each time a stob of pain occurs. The pain occurs very suddenly and then shoots along one side of the face. It usually begins at a specific part of the nerve called the *trigger zone*. It may then spread along branches of the nerve, but it never involves other nerves. The pain may last a few hours or several weeks. It may then disappear for a few months or years, but it usually returns.

**Glossopharyngeal neuralgia** is a very rare condition. It affects the throat and the back of the tongue. Temporary relief for both types of neuralgia may be obtained by using drugs, or by numbing the nerve with an injection of alcohol. If the pain does not disappear, the only cure is a surgical operation to remove part of the nerve.

See also Neuritis.

**Neuritis, nu RY ths**, is an inflammation of a nerve that is caused by disease or injury. It is a painful condition that may affect one or many nerves. Neuritis is some-times confused with a disorder called neuralgia (see Neuralgia).

Bacteria, viruses, and diet and vitamin deficiencies can cause neuritis. Infections, such as tuberculosis, syphilis, and *herpes zoster* (shingles), can invade a nerve, resulting in neuritis. Neuritis can also develop when a disease, such as diabetes, changes the activities of the body's cells. Neuritis caused by physical injury to a nerve involves only the injured nerve.

If neuritis continues for a long time, a nerve may become so badly damaged that it can no longer function properly. As a result, a person may lose the ability to sense heat, pressure, and touch. The body also may lose control over such automatic activities as sweating. If a nerve no longer can stimulate a muscle, the muscle wastes away and eventually becomes paralyzed. Neuritis requires a doctor's care.

**Neurofibromatosis**, often abbreviated as *NF*, is an incurable hereditary disorder that affects the nervous system and the skin. NF is sometimes called *elephant man's disease* after the Englishman Joseph Merrick, whose disfigurement was mistakenly thought to have been caused by NF. In the 1980's, experts concluded that Merrick actually had a rarer disease called *Proteus syndrome*. NF may range in severity from a mild disorder to a severely disfiguring one. There are two forms of the disorder, called NF-1 and NF-2.

NF-1, also called *von Recklinghausen's disease*, is more common and less severe. It occurs in about 1 out of every 4,000 births. The major signs are flat, light brown spots on the skin called *cafe-au-lait spots*, and *benign* (noncancerous) tumors of the nerves. The tumors, called *neurofibromas*, often develop just beneath the surface of the skin, producing small to large skin growths. Tumors may affect many other parts of the body, including the bones. Many people with NF-1 have *scoliosis* (curvature of the spine). In some cases, tumors affect vital organs, and NF-1 may be life-threatening. Cafe-au-lait spots are usually present at birth. Neurofibromas usually appear at puberty.

NF-2, also called *bilateral acoustic neurofibromatosis*, is much rarer than NF-1, occurring in about 1 out of every 50,000 births. NF-2 is characterized by tumors in the brain, on the spinal cord, and on the nerves that control hearing. The tumors may lead to deafness, chronic headache, vision problems, partial paralysis, and, eventually, death. The first signs of NF-2 usually appear in the teens or early twenties.

The child of a person with NF has a 50 percent chance of inheriting the disorder. However, about half of all NF victims have no family history of the disorder. There is no treatment other than surgical removal of the tumors. However, hopes for finding a treatment were raised in 1990, when researchers identified the gene responsible for NF-1. This gene produces a protein, called *neurofibromin*, that researchers believe causes the disorder.

**Neurology, nu RAHL uhh jee**, is the field of medicine concerned with the diagnosis and treatment of diseases of the nervous system and muscles. The nervous system consists of the brain, spinal cord, and nerves (see Nervous system). Neurologists are physicians who receive special training in neurology after completing medical school. Neurologists evaluate and treat patients who
Neuropathology, *NUR oh puh THAHL uh jee*, is the science that studies alterations produced by diseases of the central nervous system, nerves, or muscles. It is also concerned with changes that result from normal activity in the nervous system. These may be changes in appearance that can be seen with the unaided eye or with an optical or electron microscope. See also Nervous system; Pathology.

**Neurosis**, *no ROH sih*s, is a general term for a relatively mild type of mental illness. Symptoms of neurosis—which include anxiety, depression, and unreasonable fears—are usually distressing but not totally disabling. Psychiatrists once used the term as a formal category of mental disorders. Conditions formerly categorized as neuroses are now known by more specific terms. The revolutionary psychological theories of Austrian physician Sigmund Freud included the concept of neurosis as a disorder caused by conflict between conscious and unconscious impulses. Nancy C. Andreasen

See also Freud, Sigmund; Mental illness.

**Neutra, NOH trah, Richard Joseph** (1892-1970), was an Austrian-born architect who worked in California. His best designs demonstrate his goal of creating buildings that meet biological and psychological needs, as well as artistic and technical considerations. In his book *Survival Through Design* (1954), Neutra stated that people can survive only by controlling their environment through design, architecture, and city planning.

Neutra was born in Vienna. He moved to the United States in 1923 and settled in Los Angeles in 1925. His most famous work is the Lovell "Health" House (1927-1929) in Los Angeles, an early example of modern European architecture in the United States. A number of Neutra's later buildings, including the Tremaine House (1948) in Santa Barbara, California, suggest a continuous flow of space by the use of vast sheets of glass and thin supports. Dennis Domen

**Neutrality** is the official status of a government that does not take part in a war. The nations that do not take part, either directly or indirectly, are called neutrals. The warring countries are called belligerents. Belligerents want to prevent their enemies from trading with neutrals. Neutrals want to stay out of the war, and expect belligerents to respect neutral territory, freedom of the seas, and the right to trade. **Neutralization** describes the position of a nation that has been recognized as permanently neutral, such as Switzerland.

Since the late 1700's, the rights and duties of neutrals and belligerents have become part of international law. But warring nations have frequently ignored these rights and duties, and in most cases it has been difficult or impossible to enforce them. The rules of neutrality have been developed through both custom and treaty. In 1907, a group of nations at the second Hague Peace Conference set down in two treaties the traditional rules of neutrality on land and sea. These rules were an attempt to balance the differing, and often conflicting, interests of neutrals and belligerents. Individual governments also pass their own laws on neutrality.

**Rights and duties.** Traditionally, a neutral must not provide military assistance to either of the belligerents. In return, belligerents must respect the rights of neutrals. They must not fight on neutral territory, or move troops across neutral countries. If belligerent troops enter neutral territory, the neutral has the right to disarm them and intern (hold) them until the war is over.

A neutral must not build or arm warships for a belligerent. During the U.S. Civil War, Britain failed to prevent the building and departure of the *Alabama* and other British warships for the Confederacy. These ships sank many Union ships. After the war, an international court ruled that Britain had violated its neutrality.

Belligerent warships may enter a neutral port in an emergency. But if they stay more than 24 hours, they can be interned. Belligerents may not use neutral ports for naval operations.

Neutrals have the right to trade with other neutrals. But belligerents may search neutral ships. If these ships are carrying war materials to the enemy, the belligerent has the right to seize the goods. Belligerents often decide for themselves what to consider as war materials. They may blockade enemy ports and seize neutral vessels that try to run (slip through) the blockade.

**World War I.** In 1914, Germany violated the rules of neutrality by invading Belgium, whose permanent neutrality had been guaranteed by treaty in 1831. The United States remained neutral in World War I from 1914 to 1917. During this time, the United States tried to defend its neutral rights at sea against violation by Britain, France, and Germany. Britain and France

---

Neutra's Lovell House in Los Angeles was one of the first homes in America with a light steel frame and an open plan.
seized cargoes bound for neutral countries such as Denmark and Norway. They argued that such cargoes might eventually reach Germany. The United States insisted that Britain and France could not interfere with neutral rights or blockade neutral ports.

In 1917, the United States declared war against Germany, partly because Germany had violated U.S. neutrality. German submarines had sunk U.S. ships without warning. Under international law, Germany could capture ships carrying war materials to the enemy. But German submarines were unable to take captured ships into port, so they sank them. The loss of lives and property helped turn U.S. public opinion against Germany.

Between wars. Conflicts over neutral rights had twice been major causes for the United States to go to war, in 1917 and in 1912 (see War of 1812 [Causes of the war]). In the 1930's, Congress passed several acts designed to keep the United States out of another war. These acts placed limits on U.S. neutral rights beyond those required by international law. They forbade the export of war materials and the extension of loans or credits to belligerents. They also provided that other goods could be exported only on a cash-and-carry basis. This meant that the belligerent had to pay cash and use its own ships to carry the goods. If the ships were sunk, the United States would not suffer any losses.

World War II. Early in World War II, Germany violated the neutrality of Belgium, Denmark, the Netherlands, Norway, and Yugoslavia. The United States soon shifted from a policy of impartial neutrality to one of aid to the Western allies. The laws of the mid-1930's were modified in November 1939 to permit the export of all materials to belligerents on a cash-and-carry basis.

When German victories threatened Britain, the United States violated its neutral obligations by sending 50 destroyers and other war materials to the British. In March 1941, Congress passed the Lend-Lease Act to aid countries fighting Nazi Germany. After Japan attacked Pearl Harbor in December 1941, the United States declared war on Japan. Germany, a Japanese ally, then declared war on the United States.

After World War II, many countries, especially in Asia and Africa, refused to support either the Communist or non-Communist blocs in the Cold War (see Cold War). These countries sought security through policies of nonalignment and noninvolvement. They were called neutralist, unaligned, or uncommitted nations. However, the idea of opposing blocs lost meaning in 1991, when the Soviet Union—the leading Communist country during the Cold War—was dissolved.

Neutrality today. Total warfare and the growth of world and regional organizations like the United Nations (UN) have made neutrality more difficult to define. Total warfare has eroded many distinctions between civilian and military activities and materials. This undercut many of the arguments neutrals previously used to support their rights of neutral trade. Collective action, such as use of a UN police force against an aggressor, is in many ways in disagreement with earlier practices of neutrality.

Robert J. Pranger

See also High seas; International law; Third World.

Neutralization, noo trueh lub ZAY shuhn, is a chemical reaction in which an acid and a base form a salt. If the reaction is complete, the final salt is usually neutral (neither acidic nor basic). Neutralization is one of the most important reactions in chemical analysis, and in many branches of industry. Processes that go on in the human body include neutralization.

Acids and bases in water solution ionize (break down) into positive and negative ions as shown below for hydrochloric acid (HCl) and sodium hydroxide (NaOH).

\[ \text{HCl} \rightarrow \text{H}^+ + \text{Cl}^- \quad \text{and} \quad \text{NaOH} \rightarrow \text{Na}^+ + \text{OH}^- \]

When the acid and base react together, the hydroxide (OH\(^{-}\)) ion from the base combines with the hydrogen (H\(^{+}\)) ion from the acid to form water (H\(_2\)O).

\[ \text{H}^+ + \text{Cl}^- + \text{Na}^+ + \text{OH}^- \rightarrow \text{Na}^+ + \text{Cl}^- + \text{H}_2\text{O} \]

The two remaining ions form a salt that usually stays in solution as ions. If the water is evaporated, the salt can be recovered in crystal form.

Neutrino is any of three types of subatomic particles that have no electric charge. Experiments have shown that neutrinos have some mass (amount of matter). However, the masses of neutrinos are so small that scientists have not yet been able to measure them directly. A neutrino has no more than 1 millionth the mass of an electron, the lightest particle that has an electric charge.

Neutrinos travel at or near the speed of light. They are produced in reactions that occur in the decay (breaking apart) of unstable subatomic particles or nuclei. They are also created in reactions that produce energy in the sun and other stars. In addition, machines known as particle accelerators can produce neutrinos.

Neutrinos belong to the lepton family of particles. The other leptons carry an electric charge and have mass. They are, from the lightest to the heaviest, the electron, the muon, and the tau.

A neutrino can change into a charged lepton by interacting with an atomic nucleus. Each type of neutrino can change into only one kind of charged lepton. The names of the three types of neutrinos come from the names of the corresponding charged leptons. Thus, an electron-neutrino can change into an electron, a muon-neutrino into a muon, and a tau-neutrino into a tau.

The neutrinos also have antimatter counterparts called antineutrinos that differ from neutrinos in the direction of their spin. Spin is a measure of the internal rotation of a particle. There are electron-antineutrinos, muon-antineutrinos, and tau-antineutrinos.

The American physicists Frederick Reines and Clyde Cowan announced the discovery of the first neutrinos, electron-neutrinos, in 1956. In 1962, the American physicists Leon M. Lederman, Melvin Schwartz, and Jack Steinberger discovered the muon-neutrino. In 2000, an international team of scientists at Fermi National Accelerator Laboratory (Fermilab) near Batavia, Illinois, announced the first direct evidence for the tau-neutrino.

Neutrinos interact with other particles through a force called the weak interaction. This force is so feeble that neutrinos can pass through a large amount of matter with only a tiny chance of interacting with a particle in the matter. So, to detect enough neutrino interactions for study, researchers must build enormous detectors.
A detector senses a neutrino indirectly, after the neutrino interacts with a nucleus or collides with an electron. The interaction or collision releases charged particles that electronic devices can detect. But the devices can also detect other charged particles at the earth’s surface. Therefore, to shield detectors from the other particles, scientists build them deep underground.

The most sensitive neutrino detector is the Sudbury Neutrino Observatory (SNO), which began operating in 1999 in a nickel mine in Ontario. The SNO detects several neutrino interactions per day. The Super-Kamiokande (Super-K) detector, in a zinc mine northwest of Tokyo, began operating in 1996 and produced much valuable data. But in 2001, an accident disabled it. A “chain reaction” of implosions (inward bursting) smashed most of its sensors, which resembled gigantic light bulbs. Authorities in Japan said that they would repair Super-K.

Neutrino detectors have consistently observed fewer neutrinos from the sun than expected. Data from the SNO show that the shortage occurs because electron-neutrinos created in the sun turn into other varieties as they travel through space. The changes can occur only if neutrinos have mass. 

Robert H. March

See also Astronomy (Neutrino astronomy); Lepton; Observatory (Neutrino observatories); Subatomic particle.

Neutron is a subatomic particle. Neutrons, together with subatomic particles called protons, form the nuclei of all atoms except ordinary hydrogen, whose nucleus consists of a single proton (see Proton). Neutrons and protons make up 99.9 percent of an atom’s mass. A cloud of electrons around the nucleus accounts for the rest of the mass (see Electron). In the nucleus, neutrons and protons are held together by a force known as the strong interaction or the strong nuclear force.

The number of neutrons in an atom of any chemical element is equal to the difference between the element's mass number (total number of protons and neutrons) and its atomic number (number of protons). The atoms of lighter elements contain about an equal number of neutrons and protons. Heavier elements contain more neutrons than protons.

Neutrons consist of fundamental particles called quarks. A neutron has no electric charge. Its diameter is approximately one millionth of a nanometer. One nanometer equals one millionth of a millimeter, or 1/25,400,000 inch. The mass of a neutron is slightly greater than that of a proton. A free neutron decays into a proton, an electron, and an antineutrino. Free neutrons have an average life span of about 15 minutes.

Sir James Chadwick, a British physicist, discovered the neutron in 1932. Today, scientists use neutrons to make various elements radioactive. They bombard atoms of the elements with neutrons in a nuclear reactor. After the nuclei of the atoms absorb neutrons, they decay by giving off radiation. When a nucleus of the uranium isotope U-235 is struck by a neutron, it becomes unstable and splits into two nearly equal parts. This process, called fission, releases a huge amount of energy and frees additional neutrons that cause more uranium nuclei to fission. A continuous series of such fissions, called a nuclear chain reaction, produces the energy in nuclear weapons and reactors.

Edward S. Fry

Neutron star is the smallest and densest type of star known. Neutron stars measure only about 12 miles (20 kilometers) across, but they have even more matter than the sun.

A neutron star forms when a large star—six to eight times more massive than the sun—runs out of fuel to burn. Because of its intense gravitational force, the star collapses. Gravity squeezes together the protons and electrons in the core of the star. As a result, the protons and electrons combine to form neutrons. The neutrons may, in turn, break down into elementary particles called quarks. The star then explodes as a supernova, throwing off its outer layers and leaving behind a spinning core—a neutron star. The core has a mass greater than 1.4 times, but less than 3 times, that of the sun. See Supernova.

A neutron star has a magnetic field billions of times stronger than the most powerful magnets on earth. This magnetic field acts like a particle accelerator. It creates an electric field that rips electrons and protons from the star’s surface. In some cases, these particles produce a beam of radio waves, X rays, or other radiation that flows from the star.

Physicists predicted the existence of neutron stars in 1938. The prediction was only a theory until 1967, when radio telescopes in England picked up regular bursts of radio waves from an object in space. Scientists later concluded that such objects, called pulsars, are actually neutron stars (see Pulsar). 

Daniel R. Stinebring
Nevada, *nuh VAD uh* or *nuh VAH duh*, is a state in the Western United States. It is a popular center of tourism. Nevada is the only state whose laws allow most kinds of gambling throughout the state. Large, luxurious gambling casinos attract visitors from all parts of the world to Lake Tahoe, Las Vegas, and Reno. Las Vegas is the largest city in Nevada and the chief tourist attraction in the state.

Nevada is a land of rugged snow-capped mountains, grassy valleys, and sandy deserts. Pine forests cover many mountain slopes, and crystal-clear streams flow through steep, rocky canyons. Large trout swim in sparkling valley lakes. In many places, geysers erupt and hot springs gush amid the rocks. In the south, bighorn sheep graze on jagged plateaus that glow red in the brilliant sunshine. Glistening white patches called alkali flats stretch across the deserts. The flowers of cactus, yucca, and sagebrush plants add splashes of color. The gray-green sagebrush gave Nevada one of its nicknames, the *Sagebrush State*. The United States government maintains a testing center for nuclear weapons in the Nevada desert.

The state's most common nickname, the *Silver State*, comes from the vast amounts of silver that were once taken from its many mines. Colorful ghost towns and historic mining towns, such as Virginia City, now attract thousands of tourists to the state every year. But mining is still one of the chief industries of Nevada. The most important minerals in the state include diatomite, gold, petroleum, sand and gravel, and silver. These resources support the state's manufacturing and processing industry.

Less rain falls in Nevada than in any other state. As a result, farming depends on irrigation. The Newlands Irrigation Project, near Reno, was the first system of its kind built by the federal government. Hoover Dam, on the Colorado River, created Lake Mead, one of the

---

The contributors of this article are Christopher H. Euline, Professor and Chairman of the Department of Geography at the University of Nevada, Reno; and James W. Hulse, Professor of History at the University of Nevada, Reno.
Interesting facts about Nevada

The city of Aurora once took part in elections in two states. When the city was first settled, its inhabitants were not sure whether it was part of Nevada or California. Elections were held in 1863, and the citizens of Aurora selected candidates for offices in both states. A survey later determined that Aurora was in Nevada.

Reuel C. Gridley, an Austin grocer, collected $275,000 in 1864 by auctioning a single sack of flour over and over again. He gave all the money to the Sanitary Fund of the U.S. Sanitary Commission, the forerunner of the American Red Cross.

Several rare species of fish live in Nevada, the driest of the 50 states. These species include the cui-ui, a large sucker found only in Pyramid Lake, and the Devils Hole pupfish, which is found only in Devils Hole. These fish evolved separately from more common fish as a result of becoming isolated as prehistoric lakes dried up.

The only United States coins with a double mint mark were those produced by the U.S. Mint at Carson City from 1870 to 1893. They bore the mark CC Gold coins, such as double eagles (face value $20), eagles ($10), and half eagles ($5), carried the distinctive mark. Silver coins, such as dollars, trade dollars, and half dollars, also had the double mint mark.

The federal government owns about 80 percent of Nevada's land. This is the largest percentage of any of the 50 states. Agencies that control the land include the Bureau of Land Management, the Fish and Wildlife Service, the Forest Service, the National Park Service, the United States Navy, and the United States Air Force.

Las Vegas is Nevada's largest city and chief tourist attraction. Caesar's Palace, shown here, is one of the city's many large, luxurious hotels and gambling casinos. Las Vegas's colorful entertainment and night life draw visitors from many parts of the world.

Lake Tahoe is a beautiful lake that lies in a valley of the Sierra Nevada mountains west of Carson City. Many people visit the lake to enjoy swimming, boating, and water-skiing.

largest artificially created lakes in the world. The dam's power plant supplies electric power for Arizona, California, and Nevada.

Nevada's main crops are alfalfa seed, hay, potatoes, and wheat. Cattle and sheep graze on vast ranches in the central and eastern areas of Nevada. Ranchers also feed their herds on public lands owned by the United States government. The U.S. government owns about 80 percent of the state's land.

Nevada lies mainly on a broad, rugged highland between the Rocky Mountains and the Sierra Nevada mountain range. In the 1820's and 1830's, the trappers Peter S. Ogden, Jedediah S. Smith, and Joseph Walker explored parts of the region in search of new fur sources. John C. Frémont began the first thorough exploration in 1843. By the 1860's, discoveries of gold and silver had brought thousands of miners to the area.

The name Nevada comes from a Spanish word meaning snow-capped. Miners and other settlers chose the name Nevada when the region became a territory in 1861. Nevada became a state in 1864 during the Civil War and was nicknamed the Battle Born State.
Symbols of Nevada
The state flag, adopted in 1929, bears a silver star. The words Battle Born signify Nevada’s admission to the Union during the Civil War. On the state seal, adopted in 1866, a railroad and a telegraph line symbolize Nevada’s importance as a corridor between the Midwest and the West Coast. A tunnel, an ore cart, and an ore-crushing mill stand for the state’s mineral wealth. A plow, a sickle, and a sheaf of wheat represent agriculture.

Land and climate
Area: 110,567 mi² (286,367 km²), including 761 mi² (1,971 km²) of inland water.
Elevation: Highest—Boundary Peak, 13,140 ft (4,005 m) above sea level. Lowest—470 ft (143 m) above sea level along the Colorado River in Clark County.
Record high temperature: 125 °F (51.7 °C) at Laughlin on June 29, 1994.
Record low temperature: −50 °F (−46 °C) at San Jacinto on Jan. 8, 1937.
Average July temperature: 73 °F (23 °C).
Average January temperature: 30 °F (−1 °C).
Average yearly precipitation: 9 in (23 cm).

Important dates
The U.S. received Nevada and other southwestern lands from Mexico under the Treaty of Guadalupe Hidalgo.
1825-1830 Peter S. Ogden reached the Humboldt River.
1848 Jedediah S. Smith crossed southern Nevada.
1859 The discovery of silver near Virginia City brought a rush of prospectors to western Nevada.
1864 Nevada became the 36th state on October 31.
State bird
Mountain bluebird

State flower
Sagebrush

State trees
Nevada has two state trees—the bristlecone pine, left, and the single-leaf pinon, right.

For information on the economy, write to Commission on Economic Development, 108 E. Proctor Street, Carson City, NV 89701-4240.

The state’s official Web site at www.state.nv.us also provides a gateway to much information on Nevada’s economy, government, and history.

Boulder Dam (now Hoover Dam) was completed.

1931 1936 1963 1980

The Nevada Legislature made gambling legal in the state.
The Nevada Legislature passed conservation laws to protect Lake Tahoe from pollution.
The U.S. Supreme Court specified how much water the states of Arizona, California, and Nevada could draw from the Colorado River.
Population. The 2000 United States census reported that Nevada had 1,998,257 people. The population had increased 66 percent over the 1990 figure, 1,201,833—by far the greatest percent increase of any of the states. According to the 2000 census, Nevada ranks 35th in population among the 50 states.

About 96 percent of Nevada's people live within the Las Vegas and Reno metropolitan areas (see Metropolitan area). The Las Vegas metropolitan area includes all of Clark and Nye counties in Nevada and Mohave County in Arizona. Over three-fourths of the people live within 50 miles (80 kilometers) of Las Vegas, Nevada's largest city. About a fifth of the people live within 30 miles (50 kilometers) of Reno, the state's second largest city.

Outside of Las Vegas and Reno, only eight of Nevada's urban areas have populations greater than 25,000. These areas are Henderson, North Las Vegas, Paradise, Spring Valley, Sunrise Manor, and Winchester, near Las Vegas; Sparks, near Reno; and Carson City, the state capital.

Hispanics account for about 20 percent of Nevada's population. African Americans make up about 7 percent.

People living in Las Vegas depend mainly on the tourist and gambling industries for their income. Las Vegas is famous for its gambling casinos and its nightclubs. Reno, another tourist favorite, is the center of banking, commerce, and transportation in northern Nevada.

Schools. The people of Nevada made plans for a tax-supported school system as early as 1861, when Nevada became a territory. In 1865, the year after Nevada became a state, the Legislature established the first school districts. Nevada had to overcome unusual problems in developing its public school system. Rural areas were thinly populated. In some places, taxpayers supported schools for as few as three or four school-age children living in a vast area. Some early schools were open only six months of the year because of a lack of funds. Until 1900, the state had only a few high schools. In some parts of Nevada, elementary school students still attend one-room schools.

In 1956, the Nevada Legislature made each of the state's counties a school district. A board of education supervises Nevada's school system. The board consists of 11 members. The voters elect the board members to

Gambling and the colorful night life in Las Vegas and Reno draw millions of tourists every year. Virginia City and other historic Nevada towns remind travelers of the prospectors who came west seeking fortunes in gold and silver. Sports enthusiasts hunt mule deer and chukar partridge, and fish for catfish, bass, salmon, and trout. Skiers race down the snow-covered slopes of the Lake Tahoe basin and the Sierra Nevada near Reno, and Mount Charleston near Las Vegas. Vacationers also enjoy swimming and water skiing at Lake Mead, Lake Tahoe, and Pyramid Lake.

Thousands of classic and vintage automobiles arrive in Reno the first week of August for Hot August Nights, one of Nevada's largest annual events. Visitors can admire the cars as they are paraded and displayed at numerous shows and events.

**Virginia City**, a famous Western historic mining town

**Places to visit**

Following are brief descriptions of some of Nevada's most interesting places to visit:

- **Austin**, a city in central Nevada, has authentic buildings from its days as a bustling mining settlement.
- **Bowers Mansion**, a large Italian-style home near Carson City, was built by "Sandy" Bowers, a silver miner who made a fortune from the Comstock Lode.
- **Fleischmann Planetarium** at the University of Nevada in Reno shows realistic motion pictures of space adventures and of hurricanes, tornadoes, and other weather conditions.
- **Hoover Dam**, about 25 miles (40 kilometers) southeast of Las Vegas, is one of the world's largest concrete dams. See Hoover Dam.
- **Pioche**, a famous county seat about 130 miles (210 kilometers) north of Las Vegas, has a historic courthouse and many remnants of its colorful past as a mining town in the 1800s.
- **Ruby Mountains** are in a scenic region southeast of Elko. The area features skiing, hiking trails, fishing, hunting, and camping. Nearby Lamoille Canyon was formed by glaciers.

**National parks and forests.** Great Basin National Park lies in east-central Nevada. It includes rugged Wheeler Peak, 3,000-year-old bristlecone pines, and limestone caves. Wildlife in the park includes eagles and bighorn sheep (see Great Basin National Park). Humboldt-Toiyabe National Forest surrounds the park. Inyo National Forests is partly in Nevada and partly in California. The northeast corner of Death Valley National Park extends into Nevada from California (see Death Valley National Park). The National Park Service maintains Lake Mead as a national recreation area (see Lake Mead).

**State parks.** Nevada has a total of 19 state parks, monuments, and recreational areas. The largest is the Valley of Fire, near Overton. The rocks in this park have been worn into odd shapes by the weather. For example, Elephant Rock has the shape of an elephant's head. Berlin-Ichthyosaur State Park, near Gabbs, features the ruins of an abandoned mining town. Lake Tahoe State Park lies on the edge of Lake Tahoe, which is 6,200 feet (1,900 meters) above sea level. For information about Nevada's state parks, special events, and activities, write to Nevada Commission on Tourism, 401 North Carson Street, Carson City, NV 89701.
Annual events

January-March
National Cowboy Poetry Gathering in Elko (January); Freestyle World Cup (January); Laughlin Desert Challenge (January); Las Vegas International Marathon (February); NASCAR Busch Series Nevada 300 (March); Mountain Oyster Cook-off in Virginia City (March).

April-June
Cinco de Mayo in Las Vegas (May); Carson City Rendezvous (June); Reno Rodeo (June); Gridley Days in Austin (June); Winnemucca Mule Show and Races (June).

July-September
National Basque Festival in Elko (July); Nevada State Fair in Reno (August); Shakespeare Festival at Sand Harbor (August); National Championship Air Races in Reno (September); Virginia City International Camel Races (September); Great Reno Balloon Race (September).

October-December
Invensys Classic at Las Vegas (October); Nevada Day Celebration and Parade in Carson City (October); Reno Celtic New Year (October); Pomegranate Art Festival in Overton (November); Hometowne Christmas in Sparks (December); Parade of Lights in Boulder City (December); National Finals Rodeo in Las Vegas (December).
Land regions. Nevada lies almost entirely within the Great Basin, a huge desert area that extends into Oregon, Idaho, Wyoming, California, and Utah (see Great Basin). The state has three main land regions: (1) the Columbia Plateau, (2) the Sierra Nevada, and (3) the Basin and Range Region.

The Columbia Plateau covers a small part of the northeastern corner of Nevada. Deep lava bedrock lies under the entire region. Streams and rivers have cut deep canyons, leaving steep ridges. The land flattens into open prairies near the Idaho border. The Sierra Nevada, a rugged mountain range, cuts across a corner of the state west and south of Carson City. Lake Tahoe and other mountain lakes in this part of Nevada attract many vacationers each year. See Sierra Nevada.

The Basin and Range Region covers the remainder of the state. It consists mainly of an upland area broken by more than 150 north-south mountain ranges. The towering Sierra Nevada marks part of the western edge of the region. The Toiyabe and Toquima ranges rise in the center of the state. In the east are the Snake and Toana ranges. Between the mountains lie buttes (lone hills) and mesas (tablelike mountains), as well as flat valleys with lakes or alkali flats (see Butte; Mesa).

The elevation of the Basin and Range Region varies from less than 500 feet (150 meters) above sea level near Lake Mohave is an artificial lake that forms part of the border between Nevada and Arizona. Engineers created the lake by building Davis Dam across the Colorado River.

The Colorado River to more than 13,000 feet (3,960 meters) in the southwest. Boundary Peak, the highest point in Nevada, rises 13,140 feet (4,005 meters) in Esmeralda County near the California border. Hot springs and geysers in many places show that Nevada is an area of dying volcanoes.

The southeastern tip of the Basin and Range Region is not part of the Great Basin. But the land here closely resembles that of the Great Basin.

Rivers and lakes. Most of Nevada's rivers are small and flow only during the wet season, from December to June. Only a few of the state's rivers have outlets to the sea. The Virgin and Muddy rivers join the Colorado in the southeastern tip of Nevada. The Owyhee (pronounced oh WYE ee), Bruneau, and Salmon rivers flow northward across the Columbia Plateau to Idaho's Snake River.

All of Nevada's other rivers empty into the Great Basin. They flow into lakes without outlets or into wide, shallow sinks (low spots in the earth). In summer, the water evaporates from the sinks and leaves salty mud flats and dry lakes. The snow-fed Humboldt River is the state's longest river. It flows westward from the mountains of Elko County for about 300 miles (480 kilometers) and empties into Humboldt Sink. The Carson River winds northeastward from California and empties into Carson Sink. The Walker River also rises in California.
and empties into Walker Lake. The scenic Truckee River flows northeastward from Lake Tahoe and empties into Pyramid Lake.

Lake Tahoe, on the Nevada-California border, is one of the nation's loveliest lakes. Lamoille, Liberty, and other beautiful lakes lie among the peaks of the Ruby Range in Elko County. Ruby and Franklin lakes are at the eastern foot of the Ruby Range. Pyramid Lake and Walker Lake are the remains of Lake Lahontan, an ancient lake that gradually dried up. Thousands of years ago, Lake Lahontan covered about a tenth of the present state of Nevada.

Lake Mead, an artificially created lake, is the only Nevada lake with an outlet to the sea. Engineers formed this vast reservoir by building Hoover Dam across a canyon of the Colorado River.

**Plant and animal life.** Broad stretches of forests cover Nevada's mountainsides. Common trees include alders, aspens, cottonwoods, firs, hemlocks, junipers, pines, spruces, and willows.

Nevada's deserts are dotted with cactus, yucca, and a variety of low brush plants. The most common desert plants include the bitter brush, mesquite, rabbit brush, sagebrush, and shadscale. Grasses grow in mountain and valley meadows. Nevada's meadows bloom in spring with Indian paintbrush, larkspur, shooting stars, and violets. In early spring, blood-red blossoms of the snow plant push through the snow in the pine forests. Wild peach blossoms and desert lilies brighten Nevada's foothills in spring and summer.

Nevada has few large animals, but hundreds of small animals live in the state. Mule deer roam the mountain forests. Pronghorns live mainly in the Charles Sheldon Antelope Refuge in Washoe County. Bighorn sheep climb the steep, rocky slopes of the Sheep Range in Clark County. Nevada's small animals include badgers, coyotes, foxes, minks, marmots, muskrats, porcupines, rabbits, and raccoons. Several kinds of lizards and snakes live in the desert. Game birds include chukar partridges, ducks, geese, pheasants, quail, and sage hens. Hundreds of white pelicans nest in the Anahoe Island Refuge in Pyramid Lake. Several kinds of trout make the state a favorite fishing spot. The cui-ui is a large sucker found only in Pyramid Lake. It was once an important food fish among the local Indians. Other fishes that swim in Nevada waters include bass, carp, catfish, and crappies.

**Average January temperatures**
The northeast has long, cool winters. Milder temperatures are found in the south and in the Reno-Carson City area.

Climate. Nevada has less precipitation (rain, melted snow, and other forms of moisture) than any other state. An average of only 9 inches (23 centimeters) of precipitation falls in Nevada annually. The driest regions of the state include the southeastern tip and the land near Carson Sink. The rainiest parts of Nevada are in the Sierra Nevada and the eastern foothills of these mountains. As much as 25 inches (64 centimeters) of rain falls annually in the Lake Tahoe region of the Sierras. Most of the rain falls during winter. Clouds moving eastward from the Pacific Ocean bring the rain. But the clouds lose most of their moisture in California as they rise over the high Sierra Nevada.

Snowfall varies widely in the state. It ranges from about 300 inches (750 centimeters) a year in the highest sections of the Sierras to about 1 inch (2.5 centimeters) a year in the southeastern part of the state.

Nevada has a wide range of temperatures. The north and the mountains in all sections have cold, long winters and short, hot summers. The west has short, hot summers, but winters there are only mildly cold. In southern Nevada, summers are long and hot, and winters are mild.

July temperatures average about 70°F (21°C) in the north and in the mountains, and 86°F (30°C) in the extreme south. January temperatures average 24°F (−4°C) in the north and 43°F (6°C) in the south. The temperature often changes greatly during the day. In Reno, for example, the temperature may change more than 45 degrees Fahrenheit (25 degrees Celsius) on a summer day. The highest temperature ever recorded in Nevada was 125°F (52°C) at Laughlin on June 29, 1994. The temperature reached a record low of −50°F (−46°C) at San Jacinto on Jan. 8, 1937.

Economy

Nevada's work force nearly doubled in size in the 1990s. But the distribution of workers did not change significantly. Service industries remain, by far, Nevada's most important industry group. Heavy tourist spending benefits such service establishments as hotels, restaurants, and ski resorts. Agriculture and manufacturing are less important in Nevada than they are in most other states. Gold is Nevada's most important mined product.

Natural resources. Nevada's chief natural resources are its vast mineral deposits, wildlife, and beautiful scenery. In some areas of Nevada, poor soil and lack of water make it difficult or impossible to raise field crops. Thick grasses in some valleys provide grazing for cattle.

Soil. Most of Nevada is covered with a grayish-brown soil. Many areas have sparse coverings of grasses and brush. With irrigation, Nevada's soil can grow grain, hay, and other crops. In some valleys, thick layers of sodium carbonate form gleaming white alkali flats, where nothing grows. These flats are sometimes called playas or dry lakes because they may be covered with water after a storm. Much of southern Nevada is covered by light gray soil high in lime or gypsum. Much of the northern section has dark soil formed from volcanic rock.

Water. Nevada has a limited water supply because of its light rainfall. Water must be carefully conserved when used for personal needs and irrigation. Farmers and ranchers pump underground water for their crops and livestock in the Carson, Diamond, Fish Lake, Mason, Smith, Spring, and White River valleys. The largest irrigation systems operate along the rivers. The Newlands system includes the Lahontan Reservoir, which stores water from the Carson and Truckee rivers. It provides irrigation water for about 75,000 acres (30,400 hectares) in Churchill and Lyon counties. Other large irrigation projects include Rye Patch Dam on the Humboldt River, Topaz Reservoir on the Walker River, and Wild Horse Dam in the Owyhee River Valley. The Robert B. Griffith Water Project provides Lake Mead water to the Las Vegas area.

Minerals. Huge deposits of copper lie in Lander, Lyon, and White Pine counties. Humboldt County is a leading mercury producer. Central and northwestern

*GSP = gross state product, the total value of goods and services produced in a year. Figures are for 1998.

Nevada have large tungsten deposits. Gold and silver have been found in many areas. Other mined resources include barite, borates, clays, diatomite, iron ore, lead, lithium, magnesite, manganese, molybdenum, perlite, salt, uranium, and zinc. Nevada also has valuable deposits of gypsum, limestone, and sand and gravel. Petroleum has been found in some eastern areas of the state.

**Service industries** account for the largest portion of Nevada's gross state product—the total value of goods and services produced by a state in a year. These industries are more important to Nevada's economy than they are to the economies of most other states. Most of Nevada's service industries are concentrated in the Las Vegas and Reno metropolitan areas. The tourist trade contributes heavily to the service industries in these areas.

Community, business, and personal services rank as the leading service industry in Nevada. This industry group accounts for about a third of the gross state product, a higher percentage than in any other state. It also employs more people than any other industry in Nevada. The community, business, and personal services industry group includes gambling—which is legal in the state—and other services in the field of amusement and recreation. Other activities in this broad industry group include the operation of private schools and hospitals; advertising and data processing firms; and cleaning establishments, hotels, and repair shops.

Every year, more than 40 million visitors enjoy Nevada's night life, lovely scenery, and exciting sports. Nevada is one of the leading states in attracting visitors from other countries. Tourist activities contribute billions of dollars to the state annually. Though gambling is legal throughout the state, about 90 percent of Nevada's large casinos are in Las Vegas, Reno, and the Lake Tahoe area. Forms of gambling include slot machines, blackjack, keno, poker, roulette, and dice games. Well-known entertainers from the United States and Europe appear in floor shows at casinos and nightclubs. Many casinos never close. Dude ranches, fishing resorts, and hunting lodges operate in many areas of the state.

Finance, insurance, and real estate form the second-ranking service industry in Nevada in terms of the gross state product. Real estate has become the most important part of this industry group as more and more people move to the state. Nevada grew faster than any other state during the 1990's. Nevada's main financial centers are Las Vegas and Reno.

Wholesale and retail trade rank third among the state's service industries. The wholesale trade of automobiles, food products, and minerals is important in Nevada. Stores and restaurants are the main types of retail establishments. Spending by tourists benefits Nevada's retail businesses.

Government ranks fourth among Nevada service industries. Government services include the operation of public schools, public hospitals, and military bases. The federal government plays a major role in Nevada's economy because it owns most of the state's land. Two federal government facilities, the Nevada Test Site and Nellis Air Force Base, employ thousands of people. The Nevada Test Site is a nuclear weapons testing facility in Nye County.

Transportation, communication, and utilities rank fifth among service industries in Nevada. Trucks are the main means of transporting freight in the state. Railroads also transport much freight. Telephone companies are the most important part of the communications sector. Utility companies supply electric, gas, and water service. More information about transportation and communication appears later in this section.

**Mining.** Gold is Nevada's most valuable mined product, accounting for more than two-thirds of the total mining income. Nevada mines about three-fourths of all the gold produced in the United States. The largest gold mines are located in the north-central part of the state in Elko, Eureka, and Lander counties. Several other Nevada counties produce significant amounts of gold. Nevada also leads all states in the production of silver. The northwestern part of the state is the leading silver-producing region, especially the area just east of Lovelock.

Among Nevada's other mined products, diatomite and barite are the most important. Diatomite is a chalky substance used mainly to make filters for liquids. Most of the state's diatomite is obtained from areas that were once lakes in western Nevada. Barite is used to create special fluids for the oil well drilling industry. Barite mines operate in Lander County. Nevada also produces clays, copper, gypsum, limestone, lithium carbonate, magnesite, oil, salt, and sand and gravel.

**Manufacturing.** Goods made in Nevada have a value
added by manufacture of about $3 \frac{1}{4}$ billion a year. Value added by manufacture represents the increase in value of raw materials after they become finished products. Leading manufactured products in the state of Nevada include printed materials, food products, concrete, and machinery. Exports from Nevada manufacturers exceed $500 million each year.

The Carson City, Las Vegas, and Reno areas are the chief manufacturing centers in the state. The Las Vegas and Reno areas have meat-packing facilities, plants that manufacture concrete, and printing and publishing companies. Plants in Reno also make electronic and computer equipment, and plastics. Factories in Sparks manufacture metal products and pet food. The Las Vegas metropolitan area has plants that manufacture processed foods, lumber products, appliances, and neon signs. A plant in Minden makes electrical machinery and equipment. Henderson has a number of chemical-processing plants and electronics factories. Companies in Carson City produce computers, construction equipment, and plastic products.

**Agriculture.** Livestock ranching is the chief agricultural activity in Nevada. Ranches and farms cover about an eighth of the state. Nevada has about 2,500 farms and ranches.

Most of Nevada's large cattle and sheep ranches are in Elko, Eureka, Humboldt, Lander, and White Pine counties. Many ranchers graze their animals for part of the year on public lands that they rent from the federal government. Ranchers sell the majority of their cattle to farmers in California, Idaho, Nevada, and the Midwestern States. Livestock owners also sell sheep, hogs, and lambs to meat packers, and wool to textile mills. Milk comes from Yerington and from areas near Reno and Las Vegas.

Irrigated farms operate chiefly near the river valleys of northern, western, and southeastern Nevada. However, irrigated farming projects have been developed throughout the state. Hay, which is used to feed livestock, is Nevada's most valuable field crop. The state's northwestern basins are the leading region for growing hay. Farmers also raise alfalfa seed, barley, onions, potatoes, and wheat.

**Electric power.** Coal-burning plants provide the majority of Nevada's electric power. Water power, gas, and oil are also used to generate electric power. Coal-burning plants operate near Las Vegas and Reno and in the east-central part of the state. Hydroelectric plants at the Davis, Hoover, and Parker dams on the Colorado River provide much of the power for southern Nevada. Geothermal plants, which are powered by underground steam, operate in Churchill, Elko, and Washoe counties.
Transportation. McCarran International Airport, in Las Vegas, is one of the busiest airports in the world. Reno also has a major airport. Four rail lines provide freight service in the state, and passenger trains serve several cities. Nevada has about 45,000 miles (72,000 kilometers) of roads and highways.

Communication. Nevada’s first printed newspaper, the Territorial Enterprise, was established at Genoa in 1858. Mark Twain, who became one of America’s greatest authors, worked as a reporter on this daily paper from 1862 to 1864, after it was moved to Virginia City. About 35 newspapers are published in Nevada, including 10 dailies. Daily papers with the largest circulations include the Las Vegas Review-Journal, the Las Vegas Sun, and the Reno Gazette-Journal. Nevada publishers also produce about 25 periodicals.

Nevada has about 50 radio stations, 15 television stations, and 8 cable television systems. Most communities have Internet access. The state’s first commercial radio station, KOH, began broadcasting from Reno in 1928. Nevada’s first television stations, KOLO-TV in Reno and KLAS-TV in Las Vegas, began operations in 1953.

Constitution of Nevada was adopted in 1864, when the state entered the Union. Nevada’s Constitution may be amended (changed) only by a majority of the voters. An amendment proposed by the Legislature must be approved by a majority of both houses in two successive regular sessions. Then the voters must approve it in the next general election.

The people may amend the Constitution directly by using the Initiative. In this procedure, voters who support the amendment first sign a petition. The number of signatures must equal at least 10 percent of the voters in the last general election in each of three-fourths of the counties, and at least 10 percent of the total number of voters in the last general election. The petition states the proposed amendment and calls for a general election to vote on it. If the amendment is approved by a majority of the voters at two successive general elections, it becomes part of the Constitution.

The Nevada Constitution may also be revised by a constitutional convention. To call such a convention, two-thirds of each legislative house must vote for it. Then a majority of voters must approve the convention in the next election.

Executive. The governor of Nevada is elected to a four-year term. The governor may serve no more than two terms.

Key state officials also are elected to four-year terms. Elected officials include the lieutenant governor, secretary of state, treasurer, controller, and attorney general. These officials may serve no more than two terms. The governor appoints the members of more than 150 bureaus, commissions, and administrative boards.

Legislature consists of a 21-member Senate and a 42-member Assembly. Nevada has 21 senatorial districts and 42 Assembly districts. Each senatorial district elects one senator. Each Assembly district elects one member to the Assembly. Members of the Senate serve four-year terms and may serve no more than three terms. Members of the Assembly serve two-year terms and may serve no more than six terms.

The Legislature meets on the third Monday of January in odd-numbered years. Legislators receive their salaries for 60 days, and legislative sessions are limited to 120 days. The governor can call special sessions.

Courts. The Supreme Court of Nevada has a chief justice and six associate justices, all of whom are elected to six-year terms. One or two justices are elected every two years. A justice in the final two years of his or her term normally serves as chief justice. Nevada has nine district courts, with 51 district judges who serve six-year terms. Court districts with large populations have divisions called departments. Each department is headed by a district judge. Municipal judges serve in Nevada’s city courts, and justices of the peace serve in the state’s townships.

Local government. Three-member boards of county commissioners govern 13 of Nevada’s 17 counties. Vot-
ers in Clark County elect a seven-member board, and voters in Lyon and Washoe counties elect five-member boards. A five-member board of supervisors governs Carson City, which is both a city and a county. County commissioners serve four-year terms. Other elected county officials include the assessor, auditor and recorder, clerk, district attorney, public administrator, and sheriff. The state's local government officials may serve for no more than 12 years. Most of Nevada's cities have a mayor-council form of government.

Revenue. Taxes account for about two-thirds of Nevada's general revenue (income). Most of the rest comes from federal grants and other U.S. government programs. A sales tax is the most important source of revenue, followed by taxes on gambling. Nevada allows many forms of gambling that are not legal in most other states. Other important sources of state revenue include taxes on alcoholic beverages, insurance, mining, motor fuel, and tobacco; and license fees for automobiles and the transportation of passengers and freight. State and local governments share revenue from a property tax. Nevada has no personal or corporate income taxes.

To attract industry, Nevada enacted a "free port" tax law in 1949. This law applies to goods being held in Nevada for shipment outside the state. It allows manufacturers to process and store such goods in Nevada without paying property taxes on them. In most states, manufacturers must pay taxes on such goods. The free port law became part of the state Constitution in 1960.

Politics. Nevada has more registered Democrats than Republicans. The Democratic Party's strength lies mainly in Clark County, where about half of the state's voters live.

In elections for governor, Democrats have won more often than Republicans. In presidential elections, voters have supported more Republican candidates than Democrats. For Nevada's votes and voting record in presidential elections, see Electoral College (table).

The governors of Nevada

History

Indian days. Some of the earliest American Indians lived in the Nevada region. Bones, ashes, and other remains discovered near Las Vegas indicate that Indians lived there thousands of years ago. Cave-dwelling Indians left picture writings on rocks in southern Nevada. Basket Makers once lived at Lovelock Cave, and Pueblo Indians lived around Las Vegas. Explorers of the early 1800's found Mohave, Paiute, Shoshone, and Washoe Indians in parts of the region.

Exploration. Francisco Garcés, a Spanish missionary, possibly was the first white man to enter the Nevada region. He may have traveled through southern Nevada while journeying from New Mexico to California in 1776. Fur traders and trappers began to explore the region between 1825 and 1830. Peter S. Ogden explored the Humboldt River valley with a group of trappers of the Hudson's Bay Company (see Hudson's Bay Company). Jedediah S. Smith led some trappers across the Las Vegas valley region into California and then back across the Great Basin.

In 1830, William Wolfskill blazed a route, called the Old Spanish Trail, from Santa Fe to Los Angeles. This trail opened Nevada to trade from the southeast. Trapper Joseph Walker blazed a trail along the Humboldt River on his way to California in 1833. Hundreds of wagons rolled westward over this same trail after gold was discovered.

Picture writings were made on rocks by cave-dwelling Indians thousands of years ago in Valley of Fire State Park.
discovered in California in 1848. Between 1843 and 1845, Lieutenant John C. Frémont explored the Great Basin and Sierra Nevada. Frémont provided the first accurate knowledge of the Nevada region.

**Early settlement.** At the end of the Mexican War in 1848, the United States acquired the Nevada region from Mexico. Nevada was then part of a territory that also included California, Utah, and parts of four other states (see Mexican War |The peace treaty|).

In 1849, the Mormon leader Brigham Young organized Utah, most of present-day Nevada, and parts of other present-day states as the State of Deseret. He asked Congress to admit his state to the Union. However, in 1850, Congress established the Utah Territory, which included Utah and most of present-day Nevada. President Millard Fillmore appointed Young governor of the territory.

In 1851, Mormons from the Great Salt Lake area in Utah built a trading post at Mormon Station (now Genoa) in the Carson Valley. The post supplied provisions for gold seekers heading for California. During the next few years, a few Mormon families came to farm and raise livestock in the Carson Valley and the surrounding region. This section of Utah Territory was organized into Carson County.

Many non-Mormons in Carson County did not want to be governed by Brigham Young. They pleaded unsuccessfully with Congress to make Carson County part of California. The Mormons themselves were troubled by a dispute with the federal government. In 1857, Young recalled the Mormon settlers to Great Salt Lake because he feared that federal troops would attack them. Two years later, the non-Mormons set up a provisional government in an attempt to establish Carson County as a separate territory. But Congress did not authorize the provisional government because only a few hundred persons lived in the Carson County area.

**The Comstock Lode,** a rich deposit of silver ore, was discovered in 1859 at the present site of Virginia City. Henry Comstock, a prospector, took credit for the discovery, though other miners actually had found the ore. News of the Comstock Lode quickly spread to fortune hunters in California and the Eastern United States. Hundreds of prospectors rushed to Carson County to "strike it rich," settling in tents, rough stone huts, and hillside caves. Almost overnight, Virginia City became a thriving mining center.

The settlers of the area led a difficult and dangerous life. They paid unbelievably high prices for provisions that had to be hauled from California over the Sierra Nevada. Some miners became millionaires. However, many other miners found little or no wealth. Many mining camps were lawless, and many miners were rowdies or gunmen.

**Nevada becomes a territory.** By 1860, the booming mining camps of Carson County held more than 6,700 people. In March 1861, President James Buchanan signed an act creating the Nevada Territory. President Abraham Lincoln, who took office two days later, appointed James W. Nye, a New York City politician, governor of the territory.

The Civil War (1861-1865) began before Nevada's territorial government could be set up in Carson City. Most Nevadans favored the North. Lincoln needed another "northern" state to support his proposed anti-slavery amendments. He knew that most Nevadans favored his Administration and would be likely to elect Republican senators who would support his policies. At the time, the Nevada Territory had far less than the 127,381 residents required by law to become a state. But Nevadans held a convention anyway and drew up a state constitution.

**Statehood.** The convention met in November 1863, but ended in failure. The voters rejected the proposed constitution because of its provisions for the taxing of mines. Congress then passed an act authorizing a second Nevada convention. In July 1864, this convention met and completed its work. In September, the revised
Historic Nevada

Basket Makers once lived at Lovelock Cave. Some of the earliest American Indians lived in the Nevada region.

John C. Frémont mapped Nevada during trips across the region from 1843 to 1845. Kit Carson acted as a guide.

The Comstock Lode, a rich deposit of silver and gold ore, was discovered at the present site of Virginia City in 1859. Prospectors flocked to the area.

Gambling was legalized in 1931 by the Nevada state legislature. Many casinos began to operate during the 1930s.

Nuclear weapons testing began in 1951 at an Atomic Energy Commission center about 60 miles (97 kilometers) from Las Vegas.

Important dates in Nevada

1776 Francisco Garces, a friar, may have become the first white person to enter the Nevada region.
1825-30 Peter S. Ogden discovered the Humboldt River. Jedediah S. Smith crossed southern Nevada.
1843-45 John C. Frémont and Kit Carson explored the Great Basin and Sierra Nevada.
1848 The United States received Nevada and other lands in the Southwest from Mexico under the Treaty of Guadalupe Hidalgo.
1859 The discovery of silver near Virginia City brought a rush of prospectors to western Nevada.
1861 Congress created the Nevada Territory.
1864 Nevada became the 36th state on October 31.
1877-81 The price of silver fell and caused many Nevada mines to close.
1880-90 Unemployed people left Nevada and the population dropped by almost 15,000.
1899 The Nevada legislature passed laws that made gambling illegal. The laws went into effect in 1910.
1931 The legislature reduced the divorce residence requirement to six weeks and also made gambling legal in the state.
1936 Boulder (now Hoover) Dam was completed.
1951 The Atomic Energy Commission began testing nuclear weapons in southern Nevada.
1963 The Supreme Court of the United States settled a 40-year dispute by specifying how much water the states of Arizona, California, and Nevada could draw from the Colorado River.
1967 The Nevada legislature changed state gambling laws to allow corporations that sell stock to the public to buy casinos and to hold gambling licenses.
1971 The Water Project (now called the Robert B. Griffith Water Project) was completed.
1980 The Nevada legislature passed conservation laws to protect Lake Tahoe from pollution.
constitution won the approval of the voters. The people elected Republican Henry G. Blasdel, a mining engineer, their first governor. President Lincoln proclaimed Nevada a state on Oct. 31, 1864.

**Mine failure and recovery.** In the 1870's, mining companies dug the richest silver ore from Nevada's mines. Some of the state's mines produced only 'low-grade' ores that contained small amounts of silver. Mine owners made a profit on these ores because silver had a high value.

During the early 1870's, the U.S. government limited the use of silver in its money system. As the government's demand for silver fell, the value of silver also dropped. As a result, many mines closed because they could no longer produce low-grade ores at a profit, and many people lost their jobs. Unemployed people began to leave Nevada by the thousands to find work elsewhere. The state's population dropped from 62,266 in 1880 to 47,355 in 1890. Several thriving communities became ghost towns.

As mining failed, ranching grew in importance. However, the ranchers also faced difficult problems. They had to pay the railroad extremely high rates to ship their stock. In addition, severe winters in the late 1880's killed thousands of cattle. Many owners of small herds became bankrupt and had to sell out to operators of large ranches.

Economic recovery began with new mineral discoveries in 1900. Prospectors found huge deposits of silver at Tonopah. They could be mined profitably, although silver still had a low value. Prospectors uncovered copper ores at Ruth and Kimberly, near Ely. In 1902, gold was discovered at Goldfield. Rich deposits discovered the next year brought thousands of miners back to Nevada.

As the mining industry came to life again, the railroads built branch lines to the mining areas. Trains brought equipment to the mines and hauled ore away to processing plants. Cattle owners also used the new branch lines for speedy beef shipments.

Nevada's Newlands Irrigation Project, the country's first federal irrigation project, was completed in 1907. In this project, dams along the Carson and Truckee rivers create irrigation reservoirs and generate electricity. Water from this system supplies an agricultural region that developed near Fallon, which is located in the west-central part of Nevada.

The richest of Nevada's gold and silver deposits were running out when the United States entered World War I in 1917. Industries then began to demand copper, tungsten, zinc, and other metals for weapons and wartime supplies. Many new mines opened in Nevada, and mine owners collected top prices for the metals. But prices fell after the war ended in 1918, and many mines closed.

In 1928, Congress authorized the construction of Hoover Dam on the Colorado River. Work on the dam began in 1930. The huge project was completed in 1936. Hoover Dam provides power and stores up irrigation water for parts of Nevada, Arizona, and California.

**Legal gambling and easy divorce.** As early as 1869, Nevada's legislature had permitted gamblers to operate games of chance in the state. By 1910, various groups of citizens had succeeded in having laws passed against gambling. But gamblers continued to operate illegally, and enforcement of the gambling laws was costly. Finally, the legislature decided it would be better to legalize gambling than to spend money trying to stop it. In 1931, Nevada made gambling legal. Many gambling casinos began to operate in the state in the 1930's.

In the early 1900's, Nevada had passed laws that made it easy to get a divorce. A person had to live in Nevada for only six months to get a divorce there. In 1927, the Nevada legislature passed a law allowing persons to obtain a divorce if they lived in the state for only three months. In 1931, the period was reduced to six weeks. During the mid-1900's, thousands of people went to Nevada each year to get divorces quickly and easily.

**The mid-1900's.** World War II (1939-1945) created new business for Nevada's mining industry. Manufacturers of military supplies purchased large amounts of the state's copper, lead, magnesite, manganese, tungsten, and zinc. After the war, mining decreased. The industry gradually switched to the production of gypsum, lime, and other nonmetallic minerals.

In the late 1940's, Nevada began a widespread campaign to attract new industry. Although the campaign brought a number of factories into the state, Nevada's economy during the 1950's and 1960's depended chiefly on nuclear research and tourism.

In 1950, the Atomic Energy Commission (AEC) set up a testing center about 60 miles (97 kilometers) northwest of Las Vegas. The next year, the AEC began testing nuclear weapons. In 1962, it began a program to develop peaceful uses of nuclear energy.

Tourism remained Nevada's largest and fastest-growing industry during the 1950's and 1960's. By the late 1960's, the Las Vegas area alone attracted annually about 15 million tourists, who spent about $400 million. Tourists also flocked to the state's two other main resort centers, Reno and the Lake Tahoe area.

In the late 1950's, the Nevada legislature set up strict gambling regulations to prevent cheating and to stop criminals from entering or influencing the gambling industry. The regulations require every gambling house to have a state license, which is issued only after investigation by the Gaming Control Board and final approval by the Gaming Commission. In 1967, the legislature passed a law allowing corporations that sell stock to the public to hold gambling licenses. The new law was a further attempt to keep the underworld out of the gambling industry.

In 1963, the Supreme Court of the United States settled a 40-year dispute between Arizona, California, and Nevada over water supplies from the Colorado River. The court ruled on how much water each state could draw from the river every year.

In 1966, Howard Hughes, an American businessman and one of the world's richest people, moved to Las Vegas. He then bought airports, casinos and hotels, large tracts of land, and a television station in the area.

In 1967, the Water Project (now called the Robert B. Griffith Water Project) was created to provide increased water supplies for the expected growth in the Las Vegas area. The final stage of the project, which brings water from Lake Mead, was completed in 1983.

**The late 1900's.** In the late 1970's, Las Vegas and Reno began projects to improve their airport facilities to accommodate a continuing increase in the number of
tourists. Reno's project was completed in 1981. Expansion of the McCarran International Airport in Las Vegas was completed in 1998.

Air and water pollution became serious problems in Nevada in the late 1900's. In one program to control water pollution, Nevada joined with California in the Tahoe Regional Planning Compact in 1980 to fight pollution of Lake Tahoe. By the 1990's, the compact had resulted in environmental improvements in the area.

**Recent developments.** Tourism remains Nevada's largest industry, but the manufacturing and construction industries are growing rapidly. The increase in tourism and the relocation of manufacturing facilities to the Las Vegas and Reno metropolitan areas have contributed to the growth of those areas. More than four-fifths of Nevada's people now live in the Las Vegas and Reno metropolitan areas.

Nevada cities face major problems as their populations continue to increase. Many of these problems require help from the state government. City dwellers are demanding better police and fire protection, improvements in education, better recreational facilities, and other services. In addition, African Americans and Indians in Nevada have made demands for equal job opportunities and rights.

Nevada, University of, is the state-supported public education system of higher education for Nevada. Its official name is the University of Nevada System. The system operates universities at Reno and Las Vegas, four two-year community colleges, and the Desert Research Institute.

Both the University of Nevada, Reno, and the University of Nevada, Las Vegas, grant bachelor’s, master’s, and doctor’s degrees. The community colleges are Truckee Meadows Community College in Reno; Community College of Southern Nevada in North Las Vegas, Henderson, and Las Vegas; Northern Nevada Community College in Elko; and Western Nevada Community College in Carson City and Fallon.

The Desert Research Institute studies atmospheric and water resources as well as other environmental concerns of desert areas. The institute has facilities located in Boulder City, Las Vegas, and Reno.

The university was chartered in 1864 and began operation in Elko in 1874. The university moved to Reno in 1886.

Critically reviewed by the University of Nevada System

Nevelson, NEHV uhl suhn, Louise (1900-1988), was an American sculptor. She became best known for her assemblages, often grouped within boxlike frames. Many of the large black walls of her compartments express a feeling of quiet and majesty.

Most of Nevelson’s assemblages are made out of wood that is painted either black or gold in the natural color. She was a pioneer in the creation of “total environments” of everyday “found” objects and utensils, strips of molding, woodwork decorations, or Victorian debris that form powerful unified wholes.

Nevelson was born in Kiev, Ukraine (then a part of the Russian Empire). She came to the United States in 1905. She studied painting at the Art Students League in New York City.

George Gumprey

Nevins, NEHV ihnz, Allan (1890-1971), an American historian and educator, twice was awarded the Pulitzer Prize for biography. Grover Cleveland: A Study in Courage won the prize in 1933, and Hamilton Fish: The Inner History of the Grant Administration received the award in 1937. He won the Bancroft Prize and the Scribner Centenary Prize for The Ordeal of the Union (1947). Nevins’s works are noted for being well balanced and thorough, with a distinctive literary style.

His John D. Rockefeller, a biography published in 1940, became very popular. It was revised and published in 1953 as Study in Power. John D. Rockefeller, Industrialist and Philanthropist. Nevins and Frank Ernest Hill completed Ford: The Times, the Man, the Company, a study of Henry Ford, in 1954.

In addition to his histories and biographies, Nevins also edited collections of the letters of noted historical people. He completed his first book, Life of Robert Rogers, in 1914, and followed it with more than 50 other volumes. His other books include The American States During and After the Revolution (1924), Frémont: The West’s Greatest Adventurer (1927), A Brief History of the United States (1942), The Emergence of Lincoln (1950), and Herbert H. Lehman and His Era (1963).

Born in Camp Point, Illinois, Nevins graduated from the University of Illinois. He wrote editorials for the New York Evening Post from 1913 to 1923 and wrote for the magazine The Nation from 1913 to 1918. Nevins joined the staff of the New York Sun in 1924, and The New York World in 1925. He was a professor of history at Cornell University in 1927 and 1928, and at Columbia University from 1931 to 1958. In 1958, he became a senior fellow of research at the Henry E. Huntington Library in San Marino, California. Nevins lectured on American history at several universities in other nations. He served as a special representative for the Office of War Information in Australia and New Zealand in 1943 and 1944, during World War II.

New Age movement is a popular cultural movement that began in the early 1970s. The movement calls for keeping the body, mind, and spirit in harmony. Its followers believe in intuition and direct experience rather than science and rational thought.

The New Age movement takes a strong interest in personal development. Followers often rely on spiritual means to achieve self-help. Mystical Asian religions play a major role in the movement’s spiritual life, especially such faiths as Zen Buddhism and the yoga school of Hinduism. New Age also emphasizes the occult (magic) and caring for the environment. Many followers believe in the coming of an astrological age of peace and love.

Healing both the body and mind is central to the movement. New Age supports a holistic approach to health, which is based on the interrelationship of many factors, including family relationships and working conditions. Many New Agers seek alternative health care, such as acupuncture and remedies made from herbs, rather than traditional medical treatments.

New Age music attempts to encourage spiritual well-being and inner peace through relaxation and meditation. New Age music typically is instrumental music that features such soothing instruments as the bamboo flute.
chimes, and tuned crystals. Richard Kyle

New Amsterdam. See New York City (History).

New Bedford (pop. 93,768; met. area pop. 175,198) is one of the leading commercial fishing ports of the United States. It is located in southeastern Massachusetts. The city lies where the Acushnet River empties into Buzzards Bay, about 50 miles (80 kilometers) south of Boston. For location, see Massachusetts (political map).

New Bedford's chief industry is the production of seafood. The city's annual fish catch has a higher value than that of any other city in the United States. The city's fishing fleet is one of the leaders in the world in catching flounders and sea scallops. Other major industries produce electric equipment, rubber goods, and textiles. The city also is a trade and distribution center of southeastern Massachusetts. It has an expanding tourist industry.

Through the years, large numbers of Portuguese immigrants have settled in New Bedford. The Feast of the Blessed Sacrament, a four-day Portuguese festival, attracts more than 100,000 visitors in August.

Wampanoag Indians lived in what is now the New Bedford area before white settlers arrived there. In 1652, a group of Pilgrims bought land from Massasoit, the Wampanoag chief, and founded a settlement. The settlement later was named for the Duke of Bedford.

New Bedford developed slowly until the 1760's, when the colonists established a whaling industry. By the mid-1800's, New Bedford had become the whaling capital of the world. The Wamsutta Mills, the city's first major textile plant, opened in 1846. New Bedford received a city charter in 1847.

New Bedford's whaling industry declined rapidly during the late 1800's, chiefly because petroleum products replaced whale oil for many purposes. Exhibits of the whaling era are featured by the New Bedford Whaling Museum in downtown New Bedford. A textile boom during the 1880's made the city a leading producer of cotton fabrics.

During the middle and late 1900's, New Bedford began several construction projects. A dike that protects the city's harbor from hurricanes was completed in 1966. In 1996, New Bedford Whaling National Historical Park was created to commemorate New Bedford's whaling industry of the 1800's. New Bedford has a mayor-council form of government.

Laurence A. Lewis

New Bern (pop. 23,128) is North Carolina's second oldest town, after Bath. It lies at the junction of the Trent and Neuse rivers, about 35 miles (56 kilometers) from the Atlantic Ocean (see North Carolina [political map]). In 1766, New Bern became the capital of the North Carolina colony and a major port. It remained the capital until 1778. The coming of the railroads in the mid-1800's contributed to the lessening of its importance as a port.

New Bern was founded in 1710 by Baron Christoph von Graffenried of Switzerland and German Palatines, who were seeking religious freedom. A colonial capital and governor's residence called Tryon's Palace was completed in 1770. The building was restored in the 1950's and is now a tourist attraction. New Bern, named for Bern, Switzerland, is the seat of Craven County. It has a council-manager government.

Jerry L. Surratt

New Britain is the largest of the more than 300 islands in the Bismarck Archipelago, which forms part of the nation of Papua New Guinea. New Britain lies off the northeast coast of New Guinea. It covers 14,093 square miles (36,500 square kilometers). Mountain ranges run the length of the island.

About 312,000 people live on New Britain. Almost all are Melanesians. The people fish and farm for a living. Most of the farming is done along the coasts. The island's north end is the most fertile area in Papua New Guinea. Rabaul is the island's largest urban community and port. It lies along the coast and has several active volcanoes around it. Rabaul suffered much damage in 1937 and 1994 when volcanoes erupted.

In 1700, the English navigator William Dampier reached New Britain. In 1884, it became a part of a German empire. Australian forces took the island from Germany in 1914, during World War I. It was given to Australia as a mandate of the League of Nations in 1920. Japan captured Rabaul in 1942, during World War II, and held the area until 1945. During the war, bombing raids destroyed most of Rabaul, but the city was rebuilt. Australia regained control of the area after the war. In 1975, New Britain became part of the newly independent nation of Papua New Guinea.

David A. M. Lea

See also Bismarck Archipelago; Papua New Guinea (map).

New Britain, Connecticut (pop. 71,538), often called the Hardware City, has long been a producer of builders' hardware and carpenters' tools. New Britain lies in central Connecticut, about 10 miles (16 kilometers) southwest of Hartford (see Connecticut [political map]). Today, many factories in New Britain still produce small hardware items. Some factories make technological goods, such as computer components.

The New Britain Museum of American Art is known for its extensive collection of American paintings. Central Connecticut State University, founded in 1849, is in the city. It includes the Copernican Planetarium and the Space Science Center. New Britain was settled in 1687 and became a city in 1870. It has a mayor-council government.

Bart Fisher

New Brunswick, New Jersey (pop. 48,573), is an educational and industrial center. It lies on the Raritan River in the north-central part of the state (see New Jersey [political map]). The city produces clothing, machinery, medical supplies, and pharmaceuticals. New Brunswick is the chief city in the metropolitan area (pop. 1,169,641) made up of Middlesex, Somerset, and Hunterdon counties. In World War II (1939-1945), nearby Camp Kilmer processed thousands of soldiers sent to Europe.

New Brunswick is the home of Rutgers, the State University of New Jersey; the New Brunswick Theological Seminary; and the State Agricultural Experiment Station. The town became a transportation center early in its history. The Raritan River was part of the land-water route from New York City to Philadelphia. New Brunswick was chartered in 1730. In the late 1900's, the city completed a number of projects in the downtown area. The new construction included office buildings, a hotel and conference center, a cultural center, shopping facilities, and an automobile bridge over the Raritan River. New Brunswick has a mayor-council form of government. It is the seat of Middlesex County.

Robert M. Hordon
New Brunswick

New Brunswick is one of the four Atlantic Provinces of Canada. Clear, swift rivers rush down the many hills and sweep through the steep valleys of New Brunswick. Forests cover about 90 percent of the land and add to its natural beauty. Saint John is New Brunswick's largest city and chief industrial and shipping center. Fredericton is the capital. Moncton is a distribution center.

Every year, loggers cut millions of trees from New Brunswick's thick forests. Many trees are sawed into lumber. Even more go to pulp and paper mills, where they are processed into a soft mass called pulp and made into paper. Newsprint, the paper used in printing newspapers, is a leading manufactured product.

The province has rich mineral and energy resources that give it great potential for industrial growth. Huge deposits of copper, lead, silver, and zinc lie in northeastern New Brunswick. In the 1950's, geologists mapped the area, and in the 1960's new facilities were built to develop the area's resources. In the 1980's, large potash mines opened in southern New Brunswick. A nuclear power plant began operating in 1982. In addition, the province has the largest oil refinery in Canada, in Saint John.

New Brunswick has some moderately rich farmland in the St. John River Valley and other regions. Potatoes rank as New Brunswick's leading field crop. Dairy farming is extensive. Lobsters and crabs are the most important seafood catches. Fishing fleets on the Bay of Fundy and the Gulf of St. Lawrence make large hauls of herring and shrimp. The rivers and rolling woodlands of New Brunswick are among the best fishing and hunting grounds in North America.

In 1922, Andrew Bonar Law of New Brunswick became the only person born outside the British Isles to serve as prime minister of the United Kingdom. Richard B. Bennett, another New Brunswicker, became prime
New Brunswick

Interesting facts about New Brunswick

Middle Island and Chatham Lake, located about 1 mile (1.6 kilometers) from each other near Chatham, are exactly the same size and shape. The Micmac Indians of eastern Canada had many legends about an Indian folk hero called Glooscap, who supposedly shaped much of their landscape. According to a Micmac legend, Glooscap once became so enraged that he scooped out a handful of earth, forming Chatham Lake, and flung it into the Miramichi River, forming Middle Island.

Middle Island and Chatham Lake

The Marco Polo, a clipper ship built in 1851 in Saint John, earned the reputation as the fastest ship in the world. The ship sailed at record speed from England to Australia and back in 1852. The Marco Polo made the round trip in just under six months.

The Bay of Fundy has the world's highest tides. They sometimes are more than 50 feet (15 meters) high in the northern part of the bay, far surpassing the world average of 2 1/2 feet (0.8 meter).

Julia Catherine Beckwith Hart wrote St. Ursula's Convent Or, The Nun of Canada, the first novel published in what later became Canada. The book was published in 1824.

Rolling hills around the village of Millville

The Port of Saint John

minister of Canada in 1930. Other well-known New Brunswickers include Bliss Carman, perhaps Canada's most famous poet; and Sir Charles Roberts, a poet, novelist, and short-story writer.

New Brunswick was named for the British royal family of Brunswick-Lüneburg (the House of Hanover). Most of its early settlers were American colonists who had remained loyal to England during the American Revolutionary War. About 14,000 of these Loyalists, as they were called, arrived during and after the war, most of them in 1783. They settled among a few thousand French-speaking Acadians and several hundred Micmac and Maliseet, or Malecite, Indians. As a result of these Loyalist settlers, New Brunswick received the nickname of the Loyalist Province. It is also called the Picture Province because of its natural beauty.

New Brunswick, along with Nova Scotia, Ontario, and Quebec, was one of the original provinces of Canada. For the relationship of New Brunswick to the other provinces, see Canada; Canada, Government of; Canada, History of.
Symbols of New Brunswick

The provincial flag, adopted in 1965, is based on the provincial coat of arms. The coat of arms, adopted in 1868, has a shield with a British lion symbolizing New Brunswick's ties to the United Kingdom. The galley represents shipbuilding and seafaring, both important in the province's history. A crest and supporters were added in 1984. The crest is a salmon bearing St. Edward's crown. Two white-tailed deer support the shield.

New Brunswick (brown) is eighth in size among the provinces and second among the Atlantic Provinces (yellow).

General information

Entered the Dominion: July 1, 1867; one of the original four provinces.
Provincial abbreviation: NB (postal).
Provincial motto: Spem Reduxit (Hope Restored).

The Legislative Building is in Fredericton, New Brunswick's capital since 1785. Some legislative sessions before 1788 were held in Saint John (then called Parrtown).

Land and climate

Area: 28,355 mi² (73,440 km²), including 520 mi² (1,350 km²) of inland water.
Elevation: Highest—Mount Carleton, 2,690 ft (820 m) above sea level. Lowest—sea level along the Atlantic coast.
Coastline: 1,410 mi (2,269 km).
Record high temperature: 103 °F (39 °C) at Nepisiguit Falls and at Woodstock on Aug. 18, 1935, and at Rexton on Aug. 19, 1935.
Record low temperature: −53 °F (−47 °C) at Sisson Dam on Feb. 1, 1955.
Average July temperature: 64 °F (18 °C).
Average January temperature: 14 °F (−10 °C).
Average yearly precipitation: 45 in (115 cm).

Important dates

1534: Jacques Cartier, a French explorer, arrived in Chaleur Bay.
1604: Samuel de Champlain and Sieur de Monts spent the winter on St. Croix Island.
1784: New Brunswick became a separate province.
1842: The New Brunswick-Maine boundary dispute was settled.
People

Population: 729,498 (2001 census)
Rank among the provinces: 8th
Density: 26 persons per mi² (10 per km²), provinces average 13 persons per mi² (5 per km²)
Distribution: 50 percent urban, 50 percent rural

Economy

Chief products

- Agriculture: milk, potatoes, chickens, beef cattle, hogs.
- Fishing industry: lobster, crab, herring, shrimp, salmon.
- Forestry: spruce, fir.
- Manufacturing: food products, paper products, wood products.
- Mining: zinc, potash, lead, silver, peat.

Gross domestic product

Value of goods and services produced in 2000: $16,967,000,000.* Services include community, business, and personal services; finance; government; trade; and transportation and communication. Industry includes construction, manufacturing, mining, and utilities. Agriculture includes agriculture, fishing, and forestry.

Government

Provincial government

Premier: term of up to 5 years
Members of the Legislative Assembly: 55; terms of up to 5 years

Federal government

Members of the House of Commons: 10
Members of the Senate: 10

Sources of information

For information on tourism in New Brunswick and on the province's economy, write to: New Brunswick Department of Economic Development, Tourism and Culture, P.O. Box 6000, Fredericton, NB E3B 5H1. The department's Web site at www.gov.nb.ca/edt is also a helpful resource. For information on the government of New Brunswick, write to: Communications New Brunswick, P.O. Box 6000, Fredericton, NB E3B 5H1. Communications New Brunswick's Web site at www.gov.nb.ca/cnb also has useful information. For information on New Brunswick's history, write to: Legislative Library, Province of New Brunswick, P.O. Box 6000, Fredericton, NB E3B 5H1.

New Brunswick became one of the original four provinces of the Dominion of Canada.

Large deposits of copper, lead, silver, and zinc were mapped in the Bathurst-Newcastle region.

Two national railway systems linked New Brunswick cities with Montreal.

Confederation Bridge, which connects New Brunswick and Prince Edward Island, opened.

1867
1890
1952-1953
1997
Population. The 2001 Canadian census reported that New Brunswick had 729,498 people. The province's population had decreased by about 1 percent since the 1996 census, which reported a population of 738,133.

About half the people of New Brunswick live in cities and towns. About a sixth of the people live in the metropolitan area of Saint John. Saint John has the province's only Census Metropolitan Area as defined by Statistics Canada.

Two other cities in New Brunswick have populations of more than 40,000. They are Moncton and Fredericton. The province has only a few other cities and towns with populations of more than 10,000.

About 96 of every 100 New Brunswickers were born in Canada. Most of the others came from the United States or the United Kingdom.

New Brunswick has two official languages, English and French. It is the only legally bilingual province in Canada. About two-thirds of the people speak English as their native language. They include descendants of the Loyalists who left the American Colonies in the 1700's. Other English speakers include descendants of English, Irish, and Scottish immigrants who arrived in the 1800's. About one-third of New Brunswick's people, called Acadians, speak French as their native language. The south and west of the province is mostly English-speaking. The Acadians are concentrated in the north and east. About 30 percent of New Brunswickers speak both languages. About 9,000 people in New Brunswick have some American Indian ancestry.

Schools. During the late 1700's, most schooling in the New Brunswick region took place in the home—or in

King Square, in downtown Saint John, is one of several charming and restful parks in the city. About a sixth of New Brunswick's people live in the metropolitan area of Saint John.

Maypole dancers perform at Mactaquac Provincial Park, which overlooks Mactaquac Dam near Fredericton. The park has beaches, a marina, camping grounds, and a golf course.
privately run schools. Most early schools were open only a few months of the year. Classes were often taught by traveling teachers. An act of 1805 established New Brunswick’s first grammar (high) school at Saint John and provided for two schools for younger pupils in each remaining county. Some of these schools became grammar schools as populations grew. An act of 1816 created a system of public schools by granting funds for education to each county. Parents and church groups also supported many schools in New Brunswick in the 1800’s. In 1871, the provincial government established a free public school system, supported by provincial grants and by county and local taxes. In 1967, the government took over all costs of public school education.

Elected district education councils administer public schools in New Brunswick. Each school also has an elected parent school support committee.

New Brunswick law requires children to attend school from age 7 to age 18 or until they graduate. A law was scheduled to go into effect in 1999 that would require children to attend school until age 18 or until they graduate. Education is available to all students in either English or French.

**Libraries.** New Brunswick has five regional library systems, with many local libraries. The provincial legislative library is in Fredericton. Other libraries include the Harriet Irving Library of the University of New Brunswick in Fredericton, the Ralph Pickard Bell Library of Mount Allison University in Sackville, and the Champlain Library of the University of Moncton.

**Museums.** The New Brunswick Museum in Saint John is Canada’s oldest museum. It was founded as the Museum of Natural History in 1842. Today, the museum has fine cultural, historical, and scientific exhibits. The Central New Brunswick Woodmen’s Museum in Boiestown has exhibits of pioneer life in the province. The Acadian Museum at the University of Moncton features material on Acadia, a region settled by the French in the 1600’s that included what is now New Brunswick. The Atlantic Salmon Museum in Doaktown has exhibits dealing with the Atlantic salmon and salmon fishing. The York Sunbury Historical Museum in Fredericton depicts the history of central New Brunswick.

### Universities

New Brunswick has four degree-granting universities that are members of the Association of Universities and Colleges of Canada.

**New Brunswick Department of Economic Development and Tourism**

Fredericton, the capital of New Brunswick, lies along the St. John River in the southwestern part of the province.
Visitor's guide

Thousands of people visit New Brunswick every year. These visitors enjoy boating and swimming off the beaches of the Northumberland Strait. In addition, the thick forests of New Brunswick offer excellent camping facilities.

New Brunswick offers some of the best fishing in North America. Fishing enthusiasts cast for fighting Atlantic salmon—the prize catch—and bass, trout, and tuna.

Many of New Brunswick's most popular attractions lie along the Bay of Fundy coastline. These attractions include Fundy National Park, Reversing Falls, and Flowerpot Rocks. The Bay of Fundy's tides are the highest in the world.

Places to visit

Following are brief descriptions of some of New Brunswick's many interesting places to visit:

Acadian Historical Village, near Caraquet, is a reconstructed Acadian settlement from 1780 to the early 1900's.

Aquarium and Marine Center, in Shippagan, displays about 80 forms of marine life from the Gulf of St. Lawrence.

Covered bridge, over the St. John River in Hartland, is 1,282 feet (391 meters) long. It is believed to be the longest covered bridge in the world. The province also has a number of other covered bridges.

Flowerpot Rocks, at Hopewell Cape in Albert County, rise in fantastic forms. These rocks are carved by tides from the Bay of Fundy.

Huntsman Marine Science Centre and Aquarium is in St. Andrews. It features films and specimens of local marine life, including lobsters, salmon, and seals.

Islands in the Bay of Fundy, Campobello, Deer, and Grand Manan islands have fine harbors for yachting and colorful fishing villages. President Franklin D. Roosevelt of the United States kept a summer home on Campobello Island. See Roosevelt Campobello International Park.

Kings Landing Historical Settlement, which is a re-created village in Prince William, shows how the Loyalist settlers in the region lived during the period from 1784 through 1890. The settlement includes a church, houses, an inn, various other businesses and shops of the period, and a reception center. It is composed mainly of original buildings that were brought from a flooded area in the province.

Loyalist House, in Saint John, was built between 1810 and 1817 by David Merritt, a Loyalist from the United States. It was restored and opened in 1960.

Magnetic Hill Complex is near Moncton. At this site, an optical illusion makes it seem as though automobiles can coast uphill. The complex also includes a zoo and a water park.

Miramichi Salmon Museum, in Doaktown, shows the life cycle of the salmon with live samples.

Reversing Falls are at the mouth of the St. John River in Saint John, New Brunswick. Here, high tides from the Bay of Fundy force the river backwards through the falls two times a day.

National parks and sites. New Brunswick has two national parks—Fundy National Park and Kouchibougac National Park. National historic parks and sites include Carleton Martello Tower, Fort Beauséjour, and St. Andrews Blockhouse. For the areas and chief features of these parks and sites, see Canada (National Park System).

Provincial parks. For information on them, write to New Brunswick Department of Tourism and Parks, Box 6000, Fredericton, NB E3B 5H1. The Web site at www.tourismnbcanada.com/web provides detailed information on the parks in New Brunswick.
Annual events

June-July
Canada's Irish Festival in Miramichi (July); Lobster Festival in Shediac (July); New Brunswick Highland Games and Scottish Festival in Fredericton (July); International Festival of Baroque Music in Lamèque (July-August).

August-September
Foire Brayonne in Edmundston (August); Atlantic Waterfowl Celebration in Sackville (August); Chocolate Fest in St. Stephen (August); Festival by the Sea in Saint John (August); Acadian Festival in Caraquet (August); Folk Song Festival in Miramichi (August); Mactaquac Craft Festival in Fredericton (September); Harvest Jazz and Blues Festival in Fredericton (September).

The City of Saint John

Roosevelt Cottage on Campobello Island

Lobster Festival in Shediac

Covered bridge over St. John River in Hartland
**Land and climate**

**Land regions.** New Brunswick is in the northeastern extension of the Appalachian mountain system of the eastern United States. This area is called the Appalachian Region. Most of it consists of wooded highlands with clear, swift rivers in steep valleys. The Coastal Lowlands, also part of the Appalachian Region, make up the rest of the province.

The highlands areas of the Appalachian Region consist of the Central Highlands, the Northern Upland, and the Southern Highlands. The Central Highlands are the highest section of New Brunswick. These rugged hills increase in height from the southwest to the northeast. Many rise over 2,000 feet (610 meters) above sea level.

The hills include Mount Carleton, which stands 2,690 feet (820 meters) high. It is the highest point in New Brunswick. Northwest of the highlands is the flatter Northern Upland, with an elevation of about 1,000 feet (300 meters). The Southern Highlands, along the Bay of Fundy, have long ridges and valleys. Most of the hills are less than 1,000 feet (300 meters) high.

The Coastal Lowlands of the Appalachian Region are sometimes called the Eastern Plains. They slope gently down toward the east from the Central Highlands to the shores of the Gulf of St. Lawrence.

**Coastline.** New Brunswick has 1,410 miles (2,269 kilometers) of coastline. Deep bays and sharp inlets break the coastal plain.

**Flat, marshy land** forms part of the Coastal Lowlands region of New Brunswick. The lowlands slope gently eastward from the Central Highlands of the Appalachian Region to the Gulf of St. Lawrence.

**Mount Carleton** is the highest point in New Brunswick. It rises 2,690 feet (820 meters) above sea level in the rugged Central Highlands of the Appalachian Region of the province.
Grand Falls flows over a cliff on the St. John River at the town of Grand Falls. The river is the longest in New Brunswick.

The coastline in many places. The Bay of Fundy is the largest bay. Its tides are the world's highest. The power of the tides generally keeps the bay's harbors free of ice in winter. But ice floes close ports on the Gulf of St. Lawrence. Other major bays include Chaleur, Chignecto, Miramichi, and Passamaquoddy.

Heavily wooded islands lie off the coast. Many of these coastal islands are summer resort areas. Numerous islands, many of which are only jagged rocks, lie in the Bay of Fundy. Grand Manan Island is the largest island in the bay. Miscou Island and Ile Lameque lie off the northeastern coast of the province.

Rivers and lakes. The St. John River, the longest of the province's many rivers, flows 418 miles (673 kilometers). It rises in Maine, and drains western New Brunswick and the lower part of the Coastal Lowlands. Its many branches include the Nashwaak, Oromocto, and Tobique rivers. The St. Croix River forms part of New Brunswick's border with Maine. The Restigouche River forms part of the border between New Brunswick and Quebec. Other major rivers include the Nepisiguit, Petitcodiac, and Southwest Miramichi.

The great tides of the Bay of Fundy rush into the Petitcodiac River and other rivers in a wall of water called a

Average January temperatures
The coastal regions of New Brunswick are milder during wintertime than the inland sections to the northwest.

Average July temperatures
New Brunswick has mild summers with generally even temperatures throughout the province.

Average yearly precipitation
Precipitation in New Brunswick is heaviest along the southern coastal region and the lightest in the northeastern area.

**Plant and animal life.** Forests cover about 85 percent of the land area of New Brunswick—a higher percentage than in any other province. Almost unbroken forest covers the central and northern areas. Most of the trees are evergreens. The principal varieties of trees in New Brunswick include spruce, balsam fir, pine, maple, and birch.

Purple violets and pink and white mayflowers carpet the forests late in spring. In summer, blackberries, blueberries, raspberries, and strawberries are plentiful. Fiddlehead ferns flourish along riverbanks.

New Brunswick offers outstanding hunting and fishing. Forest animals include beavers, black bears, deer, moose, rabbits, skunks, and squirrels. Game birds include ducks, geese, partridges, pheasants, and woodcocks. Game fish include Atlantic silver salmon, bass, landlocked salmon (salmon in freshwater lakes), and trout.

**Climate.** New Brunswick’s coastal regions have quick changes in temperature, but the seasonal differences are not so great as those inland. Saint John, on the coast, averages 18 °F (−8 °C) in January and 62 °F (17 °C) in July. Inland, Fredericton averages 14 °F (−10 °C) in January and 67 °F (19 °C) in July. The record low, −53 °F (−47 °C), was set at Sisson Dam on Feb. 1, 1955. The record high was 103 °F (39 °C) in Nepisiguit Falls and Woodstock on Aug. 18, 1935, and in Rexton on Aug. 19, 1935.

Northern New Brunswick’s precipitation (rain, melted snow, and other forms of moisture) averages 43 inches (108 centimeters) a year. The southern part of the province receives 48 inches (122 centimeters) a year. Snowfall in New Brunswick averages about 124 inches (314 centimeters) a year.

### Economy

In the early days, the economy of the New Brunswick region was based chiefly on the timber trade and fishing. Agriculture and shipbuilding became important during the 1800’s. Today, service industries make up the largest part of New Brunswick’s gross domestic product (GDP)—the total value of all goods and services produced in a province in a year.

**Natural resources.** The forests and wildlife of New Brunswick are important natural resources. Wilderness covers much of the land, and rugged terrain interfered with the early development of the province’s minerals and other resources.

**Minerals.** The northeastern part of New Brunswick has large reserves of metallic minerals. These deposits include copper, lead, silver, and zinc. The southeastern part of the province has a major potash deposit. Bituminous coal deposits lie just north of Grand Lake. New Brunswick also has reserves of clay, gold, limestone, peat, and sand and gravel.

**Soil** is not very fertile in most of New Brunswick. Farmers must use lime and fertilizers to make this soil productive. The flood plains of some rivers have a varying depth of extremely fertile black soil. Marshes and peat bogs cover parts of the east coast.

**Service industries** provide the largest portion of New Brunswick’s gross domestic product. The leading service industry is made up of community, business,
and personal services. This industry involves the operation of such establishments as hotels, hospitals, restaurants, and schools. Other service industries include finance, insurance, and real estate; wholesale and retail trade; transportation and communication; and government. Saint John and Moncton are the centers of trade and finance in New Brunswick. Fredericton, the provincial capital, is the center of government activities. Many of the province's service industries benefit from spending by tourists. Transportation and communication are discussed later in this section.

**Manufacturing.** Goods made in New Brunswick have a value added by manufacture of about $3.5 billion Canadian dollars yearly. This figure represents the difference between the value of raw materials and the value of the finished products made from the raw materials.

Food and beverage processing ranks second among New Brunswick's manufacturing activities. Frozen potatoes are the province's leading food product. Large plants in Florenceville and Grand Falls make frozen French fries. Other leading food and beverage products are baked goods, beer, dairy products, fish products, packaged meats, and soft drinks.

Wood products rank third. The province's wood products include lumber, doors, and window frames.

**Economy of New Brunswick**

This map shows the economic uses of land in New Brunswick and where the province's leading farm, mineral, and forest products are produced. Manufacturing centers are shown in red.

- Mostly cropland
- Mostly grazing land mixed with woodland
- Forest land
- Manufacturing and service industry center
- Mineral deposit

A huge paper mill operates in Saint John. The production of paper products is an important manufacturing activity in New Brunswick.

Other important types of manufactured products made in New Brunswick include clay and cement products, fabricated metal products, petroleum products, printed materials, transportation equipment, and wood products. Structural metals for construction are the leading fabricated metal products. Facilities in Miramichi and Lameque manufacture transportation equipment, and Saint John has a large shipyard.

**Mining.** Metals provide the largest portion of New Brunswick's mining income. Zinc is the leading metal, followed by silver and lead. Most metal mining occurs in the Bathurst area. Peat, used primarily as fertilizer, is harvested in the northeast. Coal is mined in the Minto-Chipman field near Grand Lake. Potash, which is used to make fertilizer, is mined in the Sussex area. Other mineral products from New Brunswick include antimony, bismuth, clay, copper, gold, limestone, peat, salt, sand and gravel, and sulfur.

**Forestry.** Most of the trees cut down in New Brunswick are balsam firs and spruces. Other commercially important trees include aspens, beeches, birches, cedars, maples, and pines. Most of the timber harvest is used to make paper. About half of New Brunswick's forestland is owned by the provincial government.

**Fishing industry.** Lobster and crab are New Brunswick's most important catches. The province's fishing crews also catch large amounts of herring, scallops, sea urchins, and shrimp. New Brunswick has a growing fishfarming industry, which produces salmon, trout, and
several other types of fish. Each year, the province exports about 300 million Canadian dollars' worth of seafood to Europe, Japan, and the United States.

**Agriculture.** New Brunswick has about 3,400 farms. They cover about 5 percent of the land. The best farmland lies in the valleys of the St. John River and its branches, and in the southeast.

Dairy products and potatoes are the leading farm products in New Brunswick. Each accounts for about a fifth of the annual farm income. River valleys provide excellent grazing for dairy cattle. Seed potatoes account for a significant part of the potato crop. Besides dairy cattle, livestock farmers also raise beef cattle, hogs, and poultry. New Brunswick has also become an important producer of nursery products and ornamental flowers. The province's farmers also produce a number of fruit and vegetable crops.

**Electric power and utilities.** About 30 percent of the electric power generated in New Brunswick is provided by a nuclear power plant at Point Lepreau, near Saint John. Plants that burn petroleum or coal provide about 35 percent of the electric power, and hydroelectric plants produce about 15 percent. New Brunswick purchases about 20 percent of its power from utilities in other provinces. The province exports electric power to Nova Scotia, Prince Edward Island, Quebec, and the Northeastern United States. Other utility companies in the province provide gas and water service.

**Transportation.** New Brunswick's busiest airports are in Fredericton, Moncton, and Saint John. Several national and regional airlines link these cities with cities in Canada and the United States.

Railroads connect the province to the major cities of Quebec and Ontario. New Brunswick's major highways run along the coastal areas and extend inward to Fredericton. The Trans-Canada Highway travels along the St. John River and through Moncton.

Saint John is one of the few seaports of eastern Canada that are free of ice all year. Transatlantic liners can dock at Saint John during the winter, even when ice shuts the ports on the Gulf of St. Lawrence.

**Communication.** The first newspaper in New Brunswick, The Royal Gazette and the New Brunswick Advertiser, was founded in 1785. Today, the province has about 25 newspapers. New Brunswick's daily papers include the Telegraph Journal of Saint John, the Daily Gleaner of Fredericton, and The Times- Transcript of Moncton. L'Acadie Nouvelle of Caraquet is a French language daily.

New Brunswick's first radio station, CFNB, began broadcasting in Fredericton in 1923. The province now has about 30 radio stations. The Canadian Broadcasting Corporation sends programs overseas from its shortwave transmitter in Sackville. New Brunswick's first television station, CHSJ-TV, began broadcasting in Saint John in 1954. The province has four major television stations, including one that broadcasts in French. Several other stations rebroadcast programming from two of the major stations. Cable television and Internet service is available throughout most of New Brunswick.

**Government**

**Lieutenant governor** of New Brunswick represents the British monarch, Queen Elizabeth II, in her role as the queen of Canada. The lieutenant governor is appointed by the governor general in council—that is, the governor general of Canada acting with the advice and consent of the Cabinet. The position of lieutenant governor is largely honorary.

**Premier** of New Brunswick is the actual head of the provincial government. The province, like the other provinces and Canada itself, has a parliamentary form of government. The premier of the province is an elected member of the Legislative Assembly. The premier is usually the leader of the majority party in the Legislative Assembly.

The premier presides over the Executive Council (cabinet). The premier chooses the Executive Council from among the members of the majority party in the Legislative Assembly. Each council member, called a minister, usually directs one or more departments of the provincial government. The Executive Council, like the premier, must resign if it loses the support of a majority of the Legislative Assembly.

**Legislative Assembly** of New Brunswick is a one-house legislature that makes the provincial laws. The Legislative Assembly is made up of 55 members who are elected from throughout the province. Terms served by the members of the Assembly may last up to five years. However, the lieutenant governor, on the advice of the premier, may call for an election before the end of the five-year period.

**Courts.** The highest court in New Brunswick is the Court of Appeal. It has a chief justice and five other justices. A panel of three judges hears most appeals, but some cases are argued before all six judges.

The Court of Queen's Bench has a chief justice and 21 other judges. The court has two divisions: the Trial Division and the Family Division. The Trial Division hears civil and criminal cases. The Family Division hears cases related to family matters, including divorce.

The governor general in council appoints judges of the Court of Appeal and Court of Queen's Bench. These judges may retire at age 65 or serve until age 73.

The Provincial Court has a chief judge and 25 other judges, all appointed by the provincial government. The court hears criminal matters, including cases involving juveniles. Lawyers may appeal Provincial Court verdicts to the Court of Queen's Bench or, in some cases, directly to the Court of Appeal.

**Local government.** The provincial government assesses and collects local taxes and administers all matters relating to education, health, welfare, and justice. City, town, and village councils handle such things as fire and police protection and maintenance of streets, sewers, and water service.

All of the cities, towns, and villages in New Brunswick have mayors and councils elected to three-year terms. Some of the cities and towns in New Brunswick also have managers.

**Revenue.** New Brunswick gets about half of its general revenue (income) from taxes levied by the provincial

government. Most of this revenue comes from taxes on personal income, property, and gasoline sales. The province also receives revenue from national and provincial tax-sharing arrangements and federal assistance. Most other revenue comes from the sale of liquor, which is under government control, and from license and permit fees.

**Politics.** The major political parties in New Brunswick are the Liberal and the Progressive Conservative parties. The Progressive Conservative Party was formerly named the Conservative Party, and today its members are usually called Conservatives. In 1991, the new Confederation of Regions Party won more seats in the Legislative Assembly than any party except the Liberal Party, but the Confederation of Regions Party lost all of its seats in the 1995 elections.

## History

**Indian days.** The first white settlers in what is now New Brunswick found Micmac and Maliseet, or Malecite, Indians living in the region. Both these tribes belonged to the Algonquian Indian family. The Micmac roamed the eastern part of the region, and the Maliseet lived in the St. John River Valley.

The Indians liked to camp downstream from waterfalls or near the farthest reaches of tidewater in rivers. These locations provided the best fishing for salmon and trout. On the coasts, the Indians gathered clams and oysters.

**Exploration and settlement.** In 1534, the French explorer Jacques Cartier arrived in Chaleur Bay. He wrote of the region: "The land along the south side of it is as fine and as good land, as arable and as full of beautiful fields and meadows, as any we have ever seen."

No further exploration took place until 1604. That year, the French explorers Samuel de Champlain and Pierre du Guas (or du Guast), Sieur de Monts, sailed into the Bay of Fundy. They explored the coast and spent the winter on St. Croix Island, near the mouth of the St. Croix River. In 1605, they moved across the Bay of Fundy to Port Royal, in what is now Nova Scotia. Later in the 1600's, French settlers arrived and established farms and fishing stations. The French called the region Acadia (see Acadia).

**French rivals.** The French, some of whom hoped to establish a fur trade, soon began to fight among themselves for control of the territory. The most famous struggle took place between Charles de la Tour and D'Aulnay de Charnisay. La Tour had a trading post and fort on the site of present-day Saint John. De Charnisay was a fur trader in Port Royal. In 1645, after many years of rivalry, De Charnisay attacked La Tour's fort while La Tour was absent. Marie de la Tour, the trader's wife, led the defense of the fort but finally surrendered. De Charnisay forced her to watch him hang all members of the garrison except one, who served as executioner.

Competition among the French gradually gave way to rivalry between the French and the English. To the south, the English colonies were growing rapidly. Many English fishing crews and other people were attracted to the New Brunswick region. The English conquered Acadia in 1654, but they returned it to the French in the Treaty of Breda in 1667. The English invaded Acadia again in 1690. After Queen Anne's War, France gave the mainland Nova Scotia area of Acadia to Britain in the Treaty of Utrecht (1713). Some Acadians remained in the New Brunswick region, however. During the last of the French and Indian wars, the British captured the region. They drove out many Acadians. The Treaty of Paris (1763) confirmed British ownership of the New Brunswick region of Acadia. See French and Indian wars.

**British settlement.** Traders from New England arrived in Saint John in 1762. In 1763, other New Englanders set up the settlement of Maugerville, near what is now Fredericton. Also in 1763, the New Brunswick region became a part of the British province of Nova Scotia. Many Acadians whom the British had driven from the region were allowed to return. The Acadians received grants of lands located in the north and east.

During and after the American Revolutionary War, about 14,000 people loyal to Britain arrived from the United States, most of them in 1783. These Loyalists, as they were called, landed in Saint John. Most of them settled in the lower St. John River Valley. They founded
New Brunswick

**Historic New Brunswick**

- **Fur traders** fought for control of the New Brunswick region during the 1600's. The British won complete control in 1763.

- **Thousands of Americans loyal to England** moved to New Brunswick during and after the Revolutionary War in America.

- **The first nuclear power plant** in the Atlantic Provinces began operating at Point Lepreau in 1982.

- **Samuel de Champlain** arrived at the mouth of the St. John River in 1604.

- **The Aroostook War** was a dispute over the New Brunswick-Maine boundary. An 1839 truce prevented any fighting.

**Important dates in New Brunswick**

- **1534** The French explorer Jacques Cartier arrived in Chaleur Bay.
- **1604** Samuel de Champlain and Sieur de Monts of France spent the winter on St. Croix Island.
- **1762** Traders from New England arrived in Saint John.
- **1763** France, in the Treaty of Paris, confirmed British ownership of the New Brunswick region.
- **1770's-1780's** Thousands of Loyalists came from the United States to settle in New Brunswick.
- **1784** New Brunswick became a separate province.
- **1825** A great fire swept the Miramichi River region.
- **1842** The New Brunswick-Maine boundary dispute was settled.
- **1848** New Brunswick was granted self-government.
- **1867** New Brunswick became one of the original four provinces of the Dominion of Canada.
- **1890** Two national railway systems linked New Brunswick cities with Montreal.
- **1952-1953** Vast deposits of copper, lead, silver, and zinc were mapped in the Bathurst-Newcastle region.
- **1968** An industrial development program was completed in the Bathurst-Newcastle region, and a hydroelectric plant opened at Mactaquac Dam on the St. John River near Fredericton.
- **1997** Confederation Bridge, which connects Prince Edward Island and New Brunswick, opened.

WORLD BOOK illustrations by Kevin Chadwick
Fredricton. Others settled near Passamaquoddy Bay on the border with the United States. In 1784, Britain established New Brunswick as a separate province. In 1785, Saint John became the first incorporated city in what is now Canada. The following year, the Colonial Legislature was created, and the farmers and landowners elected the province's first Legislative Assembly.

The timber trade with the United Kingdom and shipbuilding grew during the 1800's. After 1815, thousands of English, Irish, and Scottish settlers came to New Brunswick because they could not find jobs in Britain.

In 1825, a great forest fire blazed through about 6,000 square miles (16,000 square kilometers) in the Miramichi River region. The fire, fanned by its own hurricane-like winds, wiped out entire settlements and killed about 150 people. The homeless settlers received clothing, money, and supplies from the other provinces, Great Britain, and the United States.

By the 1830's, about four-fifths of New Brunswick was still crown lands (lands held in the name of the British government). Timber traders had to pay fees to operate in the forests. In 1833, the provincial legislature began a movement to acquire the crown lands. The British government gave the lands to New Brunswick in 1837.

The Aroostook War. Settlers from New Brunswick and Maine lived in the valley of the Aroostook River. Britain and the United States had never agreed on a boundary in this region, and disputes developed between New Brunswick and Maine loggers. The climax came in 1839 when militias from New Brunswick and Maine assembled to fight. No fighting took place, however. President Martin Van Buren of the United States sent U.S. Army General Winfield Scott to settle the dispute, which was called the Aroostook War. Scott arranged a truce. In 1842, British and American authorities established the New Brunswick-Maine boundary.

As the population of New Brunswick grew, there were increasing demands for less political control by Britain. Political power shifted gradually from the British colonial office in London to the provincial legislature in Fredericton. In 1848, Britain granted New Brunswick almost complete control over its own affairs.

Confederation and progress. In 1864, delegates from New Brunswick, Nova Scotia, and Prince Edward Island met in Charlottetown, Prince Edward Island, to discuss forming a united colony. Delegates from Upper Canada and Lower Canada, the southern parts of what are now Ontario and Quebec, joined them and proposed a confederation of all the British provinces of eastern North America. The delegates met again later in 1864 in Quebec. They drew up a plan for Canadian confederation that led to the creation of the Dominion of Canada.

Many New Brunswickers feared they would lose their political powers in the proposed union. Samuel L. Tilley, a provincial political leader, played a major part in convincing the people that the larger provinces would not control them. On July 1, 1867, New Brunswick became one of the four original provinces of the Dominion of Canada. The others were Nova Scotia, Ontario, and Quebec. Andrew R. Wetmore, of the Confederation Party, became the first premier of New Brunswick after confederation. The most prominent premier in the years following confederation was George E. King, who passed the act establishing free public schools in 1871.

The province's fishing, lumbering, and mining industries expanded gradually. But the increasing use of iron steamships led to the end of New Brunswick's sailing-ship industry. It was replaced by important textile and iron industries. During the 1870's and 1880's, many New Brunswickers moved to western Canada and the United States. These regions offered better job opportunities.

By 1890, two national railway systems linked cities in New Brunswick with Montreal. Saint John ranked with Halifax, Nova Scotia, as a chief winter port on Canada's east coast. However, Ontario and Quebec controlled manufacturing and trade in Canada. After 1900, the pulp industry became increasingly important in New Brunswick. Public works programs improved communication and transportation in the province during the early 1900's. But New Brunswick's industries suffered serious decline between 1919 and 1925. Recovery came slowly. The major growth during the 1920's and 1930's occurred in the paper industry.

The mid-1900's. After World War II (1939-1945), the province's pulp and paper industries expanded greatly, and shipbuilding became important in the Saint John area. Huge deposits of copper, lead, silver, and zinc were mapped in the Bathurst-Newcastle region in 1952 and 1953. In 1953 and 1957, the province completed hydroelectric plants that provided additional power for mining and manufacturing. The largest oil refinery in...
Canada was constructed in Saint John in 1960.
A construction program related to the Bathurst-Newcastle metal ore deposits began in 1962 and was completed by 1968. Projects in the program included chemical and fertilizer plants, docking and shipping facilities, milling and manufacturing firms, mines, and pipelines. Mining of the metal ores began to boom in 1964, when the region's largest mine started operations.
In 1968, a hydroelectric plant opened at Mactaquac Dam on the St. John River near Fredericton. More than half the power from this plant goes to industries in the Bathurst-Newcastle region.
During the late 1960's, Premier Louis J. Robichaud, a Liberal, led the province in what he called a Program of Equal Opportunity. In this program, the provincial government took over the operation of all courts, schools, and health and welfare institutions. The action was taken to equalize the quality of services provided by such facilities throughout the province.
In 1969, the New Brunswick Legislative Assembly passed a law that made French an official language of equal status with English in the legislature itself and in courts, government offices, and schools. Later that year, the Canadian Parliament passed the Official Languages Act. This law requires federal facilities to provide service in both languages in districts where at least 10 percent of the people speak French. Under this law, the whole province of New Brunswick is considered a bilingual district for federal services.

Recent developments. New Brunswick's shipping facilities were enlarged in 1970 when North America's first deepwater terminal for oil tankers opened near Saint John. In 1971, a terminal to handle ships that carry cargo in large wooden containers opened at the port of Saint John. In the mid-1970's, the Saint John area experienced major industrial expansion. The chief projects included enlargement of shipbuilding and oil refining complexes. Food-processing, mining, and pulp and paper industries are also expanding in New Brunswick.

In 1982, the first nuclear power plant in Canada's Atlantic Provinces began operation at Point Lepreau. In 1984 and 1985, large potash deposits in southern New Brunswick's Sussex area were brought into production. In 1997, however, continued flooding in the larger of the two mines in the area caused it to be closed. Today, a major concern of provincial leaders is how to provide jobs for the growing labor force.

In 1997, Confederation Bridge opened. It extends over the Northumberland Strait to connect New Brunswick and Prince Edward Island.

New Brunswick, BRUHNZ wihk, University of, is a provincially supported school with campuses located in Fredericton and Saint John, New Brunswick. It offers courses in administration, arts, computer science, data analysis, education, engineering, forest engineering,
forestry, law, marine biology, nursing, office management, physical education and recreation, and science. The university grants bachelor’s, master’s, and doctor’s degrees. It was formed in 1785 as the Provincial Academy of Arts and Sciences. It took its present name in 1839.

Critically reviewed by the University of New Brunswick

New Caledonia is an overseas possession of France. It lies in the South Pacific Ocean, about 1,200 miles (1,930 kilometers) northeast of Sydney, Australia. For location, see Pacific Islands (map). New Caledonia consists of one main island, also called New Caledonia, or Grand Terre; the Loyalty Islands; the Bêlep Islands; the Isle of Pines; and a few uninhabited islands. The mountainous main island covers 6,467 square miles (16,749 square kilometers). The rest of the islands have a total area of only 899 square miles (2,330 square kilometers).

New Caledonia has a population of about 197,000. Nouméa, on the main island, is the capital and only city. Melanesians, also called Kanaks, are the largest group of people and make up about two-fifths of the population. Europeans are the second largest group. Others include Indonesians, Polynesians, and Vietnamese.

New Caledonia is one of the world’s leading producers of nickel. Nickel mining and smelting are the leading industries. Other minerals produced in New Caledonia include chromite and cobalt. Farmers raise their own food and small amounts of coffee and copra for export. Tourism is another important industry.

New Caledonia’s governmental responsibilities are shared by a locally elected congress and a French official appointed by the French government. The congress appoints a president and up to 10 other officials to carry out executive functions.

Melanesians, probably from New Guinea, reached New Caledonia at least 4,000 years ago. In 1774, James Cook, a British navigator, became the first European to land on the main island. He called it New Caledonia because it resembled Scotland (Caledonia in Latin). France took possession of New Caledonia in 1853. The United States had a large military base on the main island from 1942 to 1945. In the 1980s, many Kanaks demanded independence for New Caledonia. In a referendum held in 1987, New Caledonians voted to continue French control. But the Melanesians continued to demand independence. In 1988, violence erupted between some Kanaks and French officials. Later that year, voters approved a peace agreement. In a referendum held in 1998, New Caledonians voted in favor of greater self-government.

Nouvea, the capital of New Caledonia, is the only city on the main island, called New Caledonia or Grand Terre.
further protection for investors. It gave the Federal Reserve Board more power to regulate loans made by banks and created the Federal Deposit Insurance Corporation (FDIC), which first insured bank deposits up to $2,500 and later, in July 1934, up to $5,000.

Congress passed the Securities Act of 1933, also called the Truth-in-Securities Act, in May 1933. This law required firms issuing new stocks to give investors full and accurate financial information. Congress created the Securities and Exchange Commission (SEC) in 1934 to regulate the sale of securities and to curb unfair stock market practices.

**Helping the farmers.** The Agricultural Adjustment Administration (AAA), created in May 1933, tried to raise farm prices by limiting production. The AAA used funds raised through a tax on processors of farm products to pay farmers not to produce as much as they had before. Farmers limited production by not planting crops on part of their land. The plan increased farm income, but critics said farmers should not cut food and cotton production at a time when people were hungry and needed clothing. The Supreme Court of the United States declared the AAA unconstitutional in 1936. The government then paid farmers to leave some land vacant as part of new soil conservation programs.

**Helping industry and labor.** The National Industrial Recovery Act of June 1933 was one of the most important of the new laws. This act created the National Recovery Administration (NRA) to enforce codes of fair practices for business and industry. Representatives of firms within each industry wrote the codes.

The industrial codes set minimum wages and maximum hours, and supported the right of workers to join unions. The codes primarily aided business. They allowed member firms to set standards of quality and establish the lowest prices that could be charged for goods. The Supreme Court declared the National Industrial Recovery Act unconstitutional in 1935, and the NRA was abolished (see Schechter v. United States).

**Helping the needy.** The Civilian Conservation Corps (CCC) launched the New Deal relief program. The CCC put young men from needy families to work at useful conservation projects, such as planting trees and building dams. The Federal Emergency Relief Administration provided the states with money for the needy. The Public Works Administration (PWA) created jobs for large numbers of people. It built thousands of schools, courthouses, bridges, dams, and other public works projects. The Home Owners Loan Corporation (HOLC) provided money at low interest for persons struggling to pay mortgages. The Tennessee Valley Authority (TVA) built dams to control floods and to provide electricity for residents of the Tennessee River Valley.

**The Second Hundred Days**

Congress approved several important relief and reform measures in 1935. These laws became the heart of the New Deal’s lasting achievements. Most of the new laws were passed during the summer, and some historians call this period *The Second Hundred Days*. Some of the most important new measures were the Works Progress Administration (WPA), the National Labor Relations Act, and the Social Security Act.

**Works Progress Administration** provided jobs building highways, streets, bridges, parks, and other projects intended to have long-range value. It also cre-

**Leading New Deal agencies**

AAA  —  Agricultural Adjustment Administration. Founded in 1933 to advise and assist farmers, and to regulate farm production.

CCC  —  Civilian Conservation Corps. Founded in 1933 to provide jobs for the unemployed.

CCC  —  Commodity Credit Corporation. Founded in 1933 to support the Department of Agriculture.

FCA  —  Farm Credit Administration. Founded in 1933 to provide a credit system for farmers by making long-term and short-term credit available.

FCC  —  Federal Communications Commission. Founded in 1934 to regulate radio, telephone, and telegraph systems.

FCIC  —  Federal Crop Insurance Corporation. Founded in 1938 to provide insurance protection against unavoidable loss of certain crops.

FDIC  —  Federal Deposit Insurance Corporation. Founded in 1933 to insure bank deposits.

FERA  —  Federal Emergency Relief Administration. Founded in 1933 to cooperate with the states in relieving hardships caused by unemployment and drought.

FHA  —  Federal Housing Administration. Founded in 1934 to insure private lending companies against loss on home-mortgage loans and on loans for improving small properties.

FSA  —  Farm Security Administration. Founded in 1937 to help farmers buy needed equipment.

HOLC  —  Home Owners Loan Corporation. Founded in 1933 to grant long-term mortgage loans at low cost to homeowners in financial difficulties.

NLRB  —  National Labor Relations Board. Founded in 1935 to administer the National Labor Relations Act.

NRA  —  National Recovery Administration. Founded in 1933 to carry out plans made by the National Industrial Recovery Act to fight the depression.

NYA  —  National Youth Administration. Founded in 1935 to provide job training for unemployed youths and part-time work for needy students.

PWA  —  Public Works Administration. Founded in 1933 to increase employment and purchasing power through the construction of useful public works, such as bridges, in the various states.

REA  —  Rural Electrification Administration. Founded in 1935 to aid farmers in the electrification of their homes.

SEC  —  Securities and Exchange Commission. Founded in 1934 to protect the public from investing in unsafe securities and to regulate stock market practices.

SSB  —  Social Security Board. Founded in 1935 to secure a sound social security system.

TVA  —  Tennessee Valley Authority. Founded in 1933 to help develop the resources of the Tennessee Valley.

USHA  —  United States Housing Authority. Founded in 1937 to aid in the development of adequate housing throughout the nation.

WPA  —  Works Progress Administration. Founded in 1935 to provide work for needy persons on public works projects. Renamed Work Projects Administration in 1939.

*Has a separate article in World Book.*
New Deal projects, such as this road construction project in New York City, put many Americans back to work. The New Deal helped the U.S. recover from the Great Depression.

ated work for artists, writers, and performers. The WPA provided some work for about 8 1/2 million people. It was renamed the Work Projects Administration in 1939.

The National Labor Relations Act guaranteed workers the right to organize unions. During the next few years, the American Federation of Labor (AFL) and the new Congress of Industrial Organizations (CIO) enrolled millions of workers in labor unions.

The Social Security Act provided pensions for the aged and insurance for the jobless. The law also provided payments for the blind and disabled and for needy children. See Social security.

The final measures

Roosevelt proposed a plan to add justices to the Supreme Court in 1937. Critics charged that he was trying to "pack" the court with judges who favored the New Deal. Roosevelt's plan divided the Democrats and cost him his solid support in Congress (see Roosevelt, Franklin D. [The Supreme Court]). Congress passed only two other important reform measures after that. The first was the United States Housing Act of 1937, which provided money for more federal public housing projects. The second was the Fair Labor Standards Act of 1938, which set a minimum wage of 25 cents an hour and a maximum workweek of 44 hours, with extra pay for extra hours. The Fair Labor Standards Act also banned children under the age of 16 from working in factories, and during school hours.

The economy faltered late in 1937. Farm prices dropped, and the number of jobless rose from about 5 million in September 1937 to almost 11 million in May 1938. The Democrats retained majorities in both houses of Congress in the 1938 elections, but Republicans gained back seats for the first time since 1928. Strong opposition in Congress forced Roosevelt to avoid further reforms, and he soon became occupied primarily with the growing threat of Nazi Germany.

Results of the New Deal

Most scholars agree the New Deal relieved much economic distress and brought about a large measure of recovery. But about 8 million Americans still had no jobs in 1940. Military spending for World War II, rather than the New Deal, brought back prosperity.

The New Deal tried to spend its way back to prosperity. It spent billions of dollars to create jobs for unemployed persons, so they could buy more and get business going normally. New Deal programs cost more money than the government received through taxes. The government borrowed much of the money it needed by selling bonds, and the federal debt grew from $22 1/2 billion in 1933 to about $40 1/2 billion in 1939.

The New Deal caused major political changes. The Democratic Party, generally a minority party since the American Civil War (1861-1865), became the largest political party. Its main strength shifted from the rural South to the urban North. Immigrants, union members, urban intellectuals, and reformers gained a stronger voice in party decisions.

Most scholars also agree that the New Deal preserved the essentials of the American free enterprise system. Profits and competition continued to play a leading part in the system. However, the program added new features. The federal government assumed responsibility for the economic security of the people and the economic growth of the nation. After the New Deal, the government’s role in banking and public welfare grew steadily. Also, organized labor became an important force in national affairs.

Additional resources

New Delhi, DEHL ee (pop. 294,783), is the capital of India. It lies on the west bank of the Yamuna River in northern India, near the Thar, or Great Indian, Desert. New Delhi is about 3 miles (5 kilometers) south of Delhi, the former capital (see India [political map]).

New Delhi is an attractive, spacious city. It contrasts sharply with the crowded, older city of Delhi. The design of New Delhi and some of its buildings reflects the influence of the British, who ruled India from 1858 to 1947. New Delhi was built in the early 1900's to replace Delhi as India's capital. It became the capital in 1931.

The city. New Delhi is a carefully planned city. It has wide, treelined avenues, and many gardens and open areas. Huge government buildings, including Parliament House and a government office building called the Secretariat, dominate the center of the city. Large houses, originally built for government officials, and smaller houses for servants are nearby.

Rashtrapati Bhavan (Presidential House), the official residence of the president of India, stands west of the
New Delhi, the capital of India, is a carefully planned city. Its wide, tree-lined avenues provide plenty of space for traffic and pedestrians. Tall, modern buildings dominate the skyline.

Secretariat. This majestic, copper-domed palace has 340 rooms. Several blocks east are white palaces that once were winter homes of Indian princes. The government turned most of the palaces into offices or museums after India became independent in 1947. The 30,000-seat National Sports Stadium is east of the palaces.

The southern part of the city includes the Diplomatic Enclave, an area set aside for foreign embassies and fine residences. High government officials of other countries have offices on a street called Shanti Path (Peace Boulevard). A temple of the Bahá’í faith is located south of the capital. The temple, built in the shape of a lotus blossom, was completed in 1986.

New Delhi has many small neighborhoods and suburbs with distinctive bazaars. Many of these neighborhoods were settled by refugees from the section of India that became part of Pakistan in 1947. New Delhi also has several beautiful gardens, of which the Mughal Gardens at Rashtrapati Bhavan are the best known.

Connaught Place, the business center of New Delhi, lies north of the Secretariat and Parliament House. It is surrounded by a fashionable shopping area.

Economy. The government of India is the main employer in New Delhi. The city has no factories. Craftworkers sell products in the Central Cottage Industries Emporium, a building near Connaught Place.

History. In 1912, the capital of India was moved from Calcutta (now Kolkata) to Delhi. Plans were also made to build a new capital just outside Delhi, away from that crowded city. The English architects Sir Herbert Baker and Sir Edwin L. Lutyens planned the layout and designed buildings for the new city. Construction began in 1912 but was delayed during World War I (1914-1918). In 1931, New Delhi was completed and became the capital of India. The city remained the capital after India gained independence from the United Kingdom in 1947. India's Constitution went into effect on Jan. 26, 1950. Since then, January 26 has been a national holiday called Republic Day. New Delhi has an annual Republic Day celebration, which features a huge parade.

See also Delhi; India (picture: New Delhi).

New Democratic Party (NDP) is a social-democratic political party in Canada. The NDP supports strong social welfare policies and associates itself with the Canadian labor movement. It favors a more equal distribution of wealth among Canadians and has supported controls on foreign investment in Canada. The NDP criticizes the country's participation in such military alliances as the North Atlantic Treaty Organization (NATO) and the North American Aerospace Defense Command (NORAD). The NDP has never had enough representation in Canada's Parliament to form a national government on its own. However, at times, it has controlled the governments of some of Canada's provinces.

The New Democrats trace their beginnings to another political party, the Co-operative Commonwealth Federation (CCF). The CCF, founded in 1932, favored placing financial institutions, health services, and key industries under government control. In 1961, the CCF formed an alliance with unions in the Canadian Labour Congress and established the New Democratic Party. Thomas C. Douglas, the premier of Saskatchewan, became the first leader of the NDP. But Douglas could not lead the New Democrats to national success. Under him, the NDP never gained much support in Quebec and the easternmost provinces of Canada.

The party had its greatest influence in Canadian federal politics from 1972 to 1974. The Liberal Party under Prime Minister Pierre Trudeau lacked a majority in Parliament. Trudeau relied on the support of the New Democrats, then led by David Lewis, a labor lawyer. During this time, the NDP's control of the balance of power resulted in the expansion of Canadian social programs. It also helped in the creation of the Foreign Investment Review Agency (FIRA)—now Investment Canada—to oversee international investments in Canadian business. In the 1974 national elections, however, the Liberals gained a majority in Parliament. As a result, the NDP's national influence weakened.

The NDP has enjoyed more success at the provincial level. New Democrats have formed governments most often in Saskatchewan, Manitoba, and British Columbia. They have also been in power in Ontario and the Yukon Territory. But the weakness of the national party organization has caused some people to suggest that the NDP merge with the Liberal Party. Those who do not favor a merger with the Liberals say that the New Democrats should renew themselves as a party of the left wing opposed to globalization. Globalization is the trend toward increased business, cultural, and governmental interaction across international borders (see Globalization).

New England is a region that consists of six states: Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, and Vermont. For information on this region, see United States (Regions). See also the articles on the states that make up the region.

New England, Dominion of, was a group of English colonies in America united in 1686 by King James II of England. The colonies in the dominion were Connect-
icut, Massachusetts, New Hampshire, East Jersey, West Jersey, New York, Plymouth, and Rhode Island. King James believed that if the colonies united under a single government, they would function better and could more easily defend themselves against England’s major military rival, France. But the colonists had no voice in the government, and most of them opposed the dominion. James was overthrown in England in 1688. The dominion broke up the next year. Donna J. Spindel

**New England Confederation** was organized in 1643. Four colonies—Massachusetts, Plymouth, Connecticut, and New Haven—formed the United Colonies of New England, as it was called. They worked to solve boundary disputes and to meet the increased danger of attacks by the Dutch, French, and Indians. Maine, New Hampshire, and Rhode Island were excluded from membership for political and religious reasons.

The four colonies agreed to “enter into a firm and perpetual league of friendship and amity, for offence and defence, mutual advice and succor upon all just occasions, both for preserving and propagating the truth and liberties of the gospel, and for their own mutual safety and welfare.”

Two commissioners from each member colony met each year to consider problems that were of mutual interest. The confederation had great power in theory, but, in practice, it could only advise. Under confederation regulations, three colonies comprised a decisive majority. A test of the confederation’s power came in 1653, when Plymouth, Connecticut, and New Haven favored a war against the Dutch of New Netherland. The fourth colony, Massachusetts, did not agree and absolutely refused to yield. This action lessened the prestige of the organization. After 1664, the commissioners met only every three years, and in 1684 the confederation came to an end. Despite serious weaknesses, the confederation provided valuable experience in discussion and cooperation among the colonies. It also helped prevent the smaller colonies from being totally dominated by Massachusetts. Albert E. Van Dusen

**New France** was the French colonial empire in North America. The empire began during the early 1600s and lasted about 150 years. At its height in the early 1700s, New France included three colonies—Canada, Acadia, and Louisiana. Canada and Acadia covered much of what is now eastern Canada. Louisiana lay in the Mississippi River Valley of the present-day United States.

The term **New France** often refers only to the colony of Canada, where about 75 percent of the empire’s settlers lived. France lost this territory to Britain in the Seven Years’ War (1756-1763). But the French influence on Canadian culture still remains strong. About 6 million Canadians, chiefly in the provinces of Quebec, Ontario, and New Brunswick, speak French. French, along with English, is an official language of Canada.

**Exploration and settlement.** The first official French expedition to North America occurred in 1524. That year, the Italian navigator Giovanni da Verrazzano explored the Atlantic Coast for King Francis I of France. The French explorer Jacques Cartier sailed to Canada in 1534, 1535, and 1541. He became the first European to reach the Gulf of St. Lawrence. Cartier claimed the area surrounding the Gulf of St. Lawrence for France.

During the 1500s, French fishing crews began to drop their nets off the coast of what is now the Canadian province of Newfoundland and Labrador. They also started to trade kettles, knives, and other European goods to local Indians for furs. Canadian furs, especially beaver pelts, became increasingly valuable because of the growing popularity of fur hats in Europe.

In 1604, the French explorers Pierre du Gua (or du Guast), Sieur de Monts, and Samuel de Champlain established Acadia along the Atlantic coast. Champlain founded the settlement of Quebec along the St. Lawrence River in 1608. Soon afterward, French fur traders established other settlements on the St. Lawrence River. Roman Catholic missionaries founded Montreal, at first named Ville-Marie, in 1642.

New France grew slowly. It had only a few thousand settlers by 1660. In 1663, King Louis XIV made New France a **royal province**, or colony, of France. Between 1665 and 1672, he sent over about 2,500 settlers. Among them were many women intended as brides for the soldiers and settlers already in the colony.

In 1672, Louis de Buade, Comte de Frontenac, became the governor general of New France. He encouraged fur traders and explorers to help expand the colony. Traders then began to establish a number of posts along the Great Lakes and Hudson Bay. Also, in 1672, the French-Canadian explorer Louis Jolliet and Jacques Marquette, a French missionary, became the first white people to find the upper part of the Mississippi River. The French explorer René-Robert Cavelier, Sieur de la Salle, followed the Mississippi to the Gulf of Mexico in 1682. He claimed the river valley for France and named it Louisiana to honor Louis XIV. In 1699, Pierre Le Moyne, Sieur d’Iberville, established the colony of Louisiana. The French built a chain of forts to link Louisiana with the rest of New France. The population of New France rose from almost 25,000 in 1720 to about 65,000 in 1760.

**Colonial life.** The chief governing officials of the royal province were the **governor general** and the **intendant**. The governor general supervised the army and relations with the Indians. The intendant controlled finance, law enforcement, and other local matters.

The fur trade was the chief economic activity in New France. Many young colonists were frontiersmen who
made their living trading for furs. They were called *courers de bois* (vagabonds of the forest) Most courers de bois became farmers after they married, and agriculture grew in importance as an economic activity. Farmers raised livestock and grew mostly wheat and oats. Fishing and lumbering also developed into important industries. In addition, the colony had a brewery, an ironworks, and a shipyard.

By law, all colonists were Roman Catholics, and the Catholic church played a major role in New France. Female religious orders provided hospitals in the towns. They also ran schools.

The towns of Quebec, Montreal, and Trois-Rivières were the centers of trade and culture. Church and government officials and wealthy landowners lived in splendid stone homes in the towns. Merchants and craft-workers had smaller stone houses. Farmers lived on sections of land called *seigneuries*. The king of France granted the seigneuries to nobles, religious groups, military officers, and merchants, who rented the land to farmers. The landowners provided their tenants with a flour mill and a church. Most farmers lived in one- or two-room log cabins.

Both farmers and townspeople in New France often enjoyed dances and other merry social gatherings. Members of the upper class attended grand balls at the residence of the governor general. In winter, the colonists had sleighing parties and held horse races on the frozen rivers.

**The British conquest.** French and English settlers began fighting for control of the fur trade in the St. Lawrence River Valley in the early 1600s. The English colonies developed along the eastern coast of North America. French expansion during the 1600s angered the English colonists, who also wanted to expand westward.

Members of the two groups and their Indian allies fought each other in a series of wars from 1689 to 1763. Great Britain gained Newfoundland, the Nova Scotia region of Acadia, and the French territory around Hudson Bay under the Treaty of Utrecht in 1713. During the next 30 years, the French built forts in the Ohio Valley and across the southern parts of what are now the Canadian provinces of Manitoba, Ontario, and Saskatchewan. Fighting began again in 1744. British colonists captured the French fort at Louisbourg on Cape Breton Island in 1745, but the French regained it in 1748.

The final struggle began in 1754. It is known as the French and Indian War in the United States. The conflict spread to Europe in 1756 and is called the Seven Years’ War in Canada and Europe. The French were winning until 1758, when British forces captured Louisbourg and several key inland forts. In 1759, the British captured Quebec. The fighting ended when the British took Montreal in September 1760. France gave up Canada and part of Louisiana to Britain in the Treaty of Paris in 1763. France had given the rest of Louisiana to Spain in 1762. France reacquired Louisiana from Spain during the early 1800s and sold it to the United States in 1803.

**New France in the early 1700s** extended from Labrador to the Gulf of Mexico and included the Mississippi River Valley. The ownership of some areas, such as the region around Hudson Bay, was disputed between France and Great Britain.

Greer, Allan. The People of New France. Univ. of Toronto Pr., 1997.

New Guinea is a large tropical island in the Pacific Ocean, north of Australia. It is the world's second largest island. Greenland is the only island larger than New Guinea.

New Guinea has an area of about 342,000 square miles (885,780 square kilometers) and a population of about 6 million. Rugged mountains cover much of the interior of the island. Most of this area has a cool climate. In contrast, the lowlands along the northern and southern coasts are hot and humid.

Most New Guineans live in villages in rural areas. Almost half of the island's people dwell in isolated mountain valleys. Until the 1930s, these New Guineans had little contact with the outside world.

Political units. The island of New Guinea contains part of one nation and all of another. Irian Jaya is part of Indonesia, and Papua New Guinea is an independent country.

Irian Jaya, sometimes called West Papua, covers the western half of New Guinea and some small nearby islands to the north and west. Three of Indonesia's provinces occupy this region. See Indonesia (table: The chief islands; New Guinea).

Papua New Guinea occupies the eastern half of New Guinea and some islands to the east, including those of the Bismarck Archipelago. Formerly a territory of Australia, Papua New Guinea became an independent nation in 1975. Port Moresby, a city on the southeast coast of New Guinea, serves as the nation's capital. See Papua New Guinea.

People. Most New Guineans are Melanesians, a people who are native to the Pacific islands. About 35,000 Asians, Australians, and Europeans also live on the island of New Guinea, most of them in coastal towns. Large numbers of people from other Indonesian islands have settled in Irian Jaya.

In the highlands, most of the villagers live in round thatched huts and grow sweet potatoes as their main food. Pigs provide most of their meat. Many lowland villagers build their houses on stilts to keep them cool and dry. Their chief food crops are bananas, taro roots, and yams. People who live in the swamps of the coastal lowlands eat mostly sago, a starch that is taken from various kinds of palm trees.

New Guineans speak more than 700 languages. Because of the number of languages, many people cannot communicate with neighbors who live only a short distance away. A growing number of eastern New Guineans speak Pidgin English, or Tok Pisin, as a second language. This lingua franca, or common language, enables speakers of different tongues to communicate with one another. In the west, many people speak Malay as a second language.

Land and climate. A great mountain system crosses New Guinea from east to west. It includes the Owen Stanley Range in the east and 16,503-foot (5,030-meter) Puncak Jaya, the highest point on the island, in the west. Mountain ridges, grassy plateaus, and deep, forested valleys cover much of the interior. Grasslands and jungles lie along the northern and southern edges of the island. Swamps with mangrove thickets border New Guinea in some areas.

Many streams and rivers flow down the mountain slopes and cross the lowlands. New Guinea's largest rivers, the Fly and Sepik, have large, swampy areas around them in the lowlands.

New Guinea's coastal lowlands have a hot, humid climate. The temperature and humidity drop as the altitude increases toward the center of the island. The annual rainfall in parts of New Guinea averages more than 200 inches (510 centimeters).

Native animals of New Guinea include crocodiles, tree kangaroos, and such snakes as the death adder, the Papuan black, and the taipan. The island also has many bright-colored birds and butterflies.

Economy of New Guinea is one of the least developed of any area in the world. Most of the people farm
the land and grow most of their own food. Many farm
people also produce goods that they sell, including co-
conuts, coffee, and cocoa. A few large plantations also
produce cocoa, coconuts, and coffee.

Two large copper mines operate on New Guinea. One
is near Nabire in Irian Jaya. Another is in Papua New
Guinea, in mountains just east of the Irian Jaya border.
These mines also yield small amounts of gold. New
Guinea also has oil and natural gas deposits.

History. The earliest settlers in New Guinea probably
migrated thousands of years ago from the Asian main-
land by way of the Malay Peninsula and Indonesia. In
1526, Jorge de Meneses, the Portuguese governor of the
Molucca Islands, became the first European to visit New
Guinea. Dutch, English, French, and Spanish explorers
stopped there during the next 300 years. The Nether-
lands claimed western New Guinea in 1828. In 1884, Ger-
many gained the northeastern part of the island, and the
United Kingdom took the southeastern part. The United
Kingdom gave its territory to Australia in 1906. After Ger-
many’s defeat in World War I (1914-1918), the League of
Nations made northeastern New Guinea a mandated ter-
rory under Australian rule (see Mandated territory).

The Japanese seized northern New Guinea in 1942,
during World War II. However, by 1944, the Allies had
reconquered the area. After the war ended in 1945, the
northeastern part became the United Nations Trust Ter-
rory of New Guinea under Australian administration.
Australia put the northeastern and southeastern units
(now Papua New Guinea) under one government in
1949.

Indonesia gained independence from the Nether-
lands in 1949 and claimed western New Guinea. In 1962,
the Netherlands agreed to turn over western New
Guinea to the United Nations (UN). The UN placed the
area under Indonesian administration in 1963, and In-
donesia renamed it West Irian. In 1969, West Irians vot-
ed to remain part of Indonesia.

During the 1960s, some New Guineans in both West
Irian and Papua New Guinea began demanding indepen-
dence. In 1969, Indonesia put down an independ-
ence movement in West Irian. The province was re-
named Irian Jaya in 1973. Australia granted Papua New
Guinea total self-government over its internal affairs in
1973. In 1975, Papua New Guinea gained complete inde-
pendence from Australia.

New Hampshire  The Granite State

New Hampshire is a New England state of the United States that is noted for its natural beauty and year-round outdoor activities. In summer, vacationers flock to the state’s rugged mountains, blue lakes, sandy beaches, and quiet villages. In the fall, visitors tour the countryside ablaze with red, orange, and yellow leaves. In winter, skiers race down snow-covered slopes and then warm themselves near crackling fires in friendly ski lodges.

The scenic beauty and other attractions bring millions of tourists from many parts of the world to tiny New Hampshire, and give the state a major source of income. But New Hampshire is more than a vacation wonder-

land. New Hampshire is the home of freedom-loving, industrious people who built a prosperous state and helped form a nation.

New Hampshire was first settled in 1623, just three years after the Pilgrims landed in Massachusetts. Early New Hampshire settlers traded in fish, lumber, and furs. They soon carved farms out of a wilderness and worked the land for food. Later, the people turned their skills and their state’s resources to industrial development. They cut down trees for the giant lumber and paper-making industries. They took minerals from the mountains and hills to start a mining industry. They used the rivers and lakes as sources of power for mills and factories. And they built ships along the state’s small Atlantic coastline. In all, the people of New Hampshire changed a wilderness into a farming society, and then into a thriving industrial state.

New Hampshire and its people have played important roles in United States history. On Jan. 5, 1776, New
Interesting facts about New Hampshire

The first state general library law was enacted by New Hampshire on July 7, 1849. The law permitted cities, towns, and school districts to raise taxes for the support of libraries. It also required that every public library established under the law be open for use by all citizens.

The Brattle organ, in historic St. John’s Episcopal Church in Portsmouth, is said to be the oldest pipe organ in the United States. Built in England and shipped to the colonies, it dates back to at least 1708. The organ is still in good condition and is played on special occasions.

The treaty ending the Russo-Japanese War was signed in 1905 in Portsmouth. President Theodore Roosevelt arranged the peace conference between the Russians and Japanese. He was awarded the 1906 Nobel Prize for peace in recognition of his work in ending the war.

Artificial rain was first used to fight a forest fire on Oct. 29, 1947, near Concord. Scientists flew over the fire in airplanes and seeded clouds with dry ice to cause the rain. The experiment was part of Project Cirrus, a weather research program conducted by the General Electric Company, the U.S. Army Signal Corps, and the Office of Naval Research.

A skier races down a slope during World Cup competition at Waterville Valley in New Hampshire's White Mountains.

Hampshire became the first of the 13 original colonies to adopt its own constitution. On June 21, 1788, it became the ninth state to ratify the United States Constitution. This act of ratification put the Constitution into effect. Since 1920, New Hampshire has held the nation's earliest presidential primary elections.

The U.S. Navy's first shipbuilding yard opened at Portsmouth in 1800. One of the country's first tax-supported public libraries was established at Peterborough in 1833. In 1853, Franklin Pierce of New Hampshire became the 14th President of the United States. Daniel Webster, a leading statesman and orator of the 1800's, was born in New Hampshire. So was Alan B. Shepard Jr., the first American astronaut to travel in space. The great poet Robert Frost lived in New Hampshire for many years.

New Hampshire's large granite deposits give it the nickname of the Granite State. Concord is the capital of New Hampshire and Manchester is the largest city.

A downtown Manchester plaza is a pleasant gathering place for local residents. Manchester is the largest city and one of the chief manufacturing centers of New Hampshire.
New Hampshire in brief

Symbols of New Hampshire
The state flag, adopted in 1909, bears the state seal. A laurel wreath with nine stars shows that New Hampshire was the ninth state to approve the U.S. Constitution. The seal, adopted in 1931, displays the Revolutionary War frigate Raleigh, which was built in Portsmouth. The American flag of 1777 flies at the ship's stern. A granite boulder in the foreground symbolizes the state's rugged terrain and the character of its people.

New Hampshire (brown) ranks 44th in size among the states and is the 3rd largest of the New England States (yellow).

General information
Statehood: June 21, 1788, the ninth state.
State abbreviations: N.H. (traditional); NH (postal).
State motto: Live Free or Die.
State song: "Old New Hampshire." Words by John F. Holmes; music by Maurice Hoffmann.

The State Capitol is in Concord, the capital since 1808. Other capitals were Portsmouth (1679-1774), Exeter (1775-1781), and several different towns between 1781 and 1808.

Land and climate
Area: 9,283 sq. mi. (24,044 km²), including 314 sq. mi. (813 km²) of inland water.
Elevation: Highest—Mount Washington, 6,288 ft. (1,917 m) above sea level. Lowest—sea level along the Atlantic coast.
Coastline: 13 mi. (21 km).
Record high temperature: 106 °F (41 °C) at Nashua on July 4, 1911.
Record low temperature: -47 °F (-44 °C) at Mount Washington on Jan. 29, 1934.
Average July temperature: 68 °F (20 °C).
Average January temperature: 19 °F (-7 °C).
Average yearly precipitation: 42 in. (107 cm).

Important dates
- 1603 - Martin Pring of England sailed up the Piscataqua River.
- 1776 - The state adopted its present constitution.
- 1784 - New Hampshire broke away from Britain and adopted a temporary constitution.

People

Population. The 2000 United States Census reported that New Hampshire had 1,223,786 people. The state's population had increased by about 11 percent over the 1990 census figure, 1,109,252. According to the 2000 Census, New Hampshire ranks 41st in population among the 50 states.

About one-third of the people live in the state's 13 incorporated cities. Six metropolitan statistical areas lie either entirely or partly within New Hampshire. Nashua and Manchester are the central cities of the only metropolitan areas located entirely within New Hampshire (see Metropolitan area). Manchester is the state's largest city. For the names and populations of these metropolitan areas, see the index of the political map of New Hampshire.

In addition to Manchester, New Hampshire's 12 other incorporated cities, in order of size, are: Nashua, Concord (the capital), Rochester, Dover, Keene, Portsmouth, Laconia, Claremont, Lebanon, Somersworth, Berlin, and Franklin. See the articles on New Hampshire cities listed in the Related articles at the end of this article.

Many of New Hampshire's people are descendants of settlers who came from Canada and many European countries. The early settlers of New Hampshire came chiefly from England, Ireland, Scotland, and Wales. After the American Civil War, thousands of French Canadians and European immigrants came to work in the state's mills, shops, and factories. Today, New Hampshire's largest population groups include people of English, Irish, French, French-Canadian, and German descent. African Americans, Asians, American Indians, and Hispanics together account for less than 5 percent of New Hampshire's population.

New Hampshire's people, like other New Yorkers, have long been called Yankees. This nickname calls to mind traits that are traditionally associated with the people of New England. These traits include business ability, thrift, conservatism, and inventiveness. See Yankee.

Schools. The New Hampshire educational system dates from colonial days, when children of the settlers attended one-room schoolhouses. Some early schoolhouses still stand. Today's public schools operate under laws passed in 1789 and substantially revised in 1919. A seven-member State Board of Education and a commissioner of education administer state laws and regulations.
Dartmouth is the oldest college in New Hampshire and one of the 10 oldest universities and colleges in the United States. The college was founded in 1769 in Hanover.

Universities and colleges

This table lists the universities and colleges in New Hampshire that grant bachelor's or advanced degrees and are accredited by the New England Association of Schools and Colleges.

New Hampshire

Visitor's guide

Visitors to New Hampshire enjoy a great variety of recreational activities in seven major vacation areas: the Great North Woods region, the White Mountains region, the Lakes region, the Seacoast region, the Merrimack Valley region, the Monadnock region, and the Dartmouth-Lake Sunapee region. Visitors to the Great North Woods enjoy such outdoor adventures as fishing, hunting, boating, and snowmobiling. The beautiful White Mountains, also in the north, attract skiers, hikers, campers, and sightseers. The skiing season generally lasts from mid-December to early April. The Lakes region of central New Hampshire provides fun for water-sports enthusiasts. The Seacoast region of the southeast has several beaches along the Atlantic Coast. Also in the south is the Merrimack Valley, where most of New Hampshire's chief cities are located. The Monadnock region, in the southwest, includes many natural beauty spots and some of the state's most interesting towns and villages. Many historic sites and educational institutions are in the Dartmouth-Lake Sunapee region in the west.

Many of New Hampshire's most popular annual events are sports contests. One of the state's best-known annual events is the League of New Hampshire Craftsmen's Fair at Mount Sunapee State Park.

Places to visit

Following are brief descriptions of some of New Hampshire's most interesting places to visit:

**Cathedral of the Pines** is an interdenominational outdoor place of worship at Rindge. In 1957, Congress made this shrine to the nation's war dead a national memorial.

**Flume** is a chasm (deep, narrow valley) 800 feet (240 meters) long at Franconia Notch. Visitors can view scenic wilderness on a 1/2-mile (0.8-kilometer) tour through the Flume.

**Hampton Beach** runs along the state's seacoast. It is one of the finest beaches on the Atlantic Ocean, and visitors enjoy many pleasant summer activities there.

**Lake Winnipesaukee** is the largest body of water in the state. It covers about 70 square miles (180 square kilometers). The lake is a popular place for sightseeing, boating, fishing, and water sports.

**Mount Washington**, near Fabyan, features a cog railway that runs 3 1/2 miles (5.6 kilometers) to the mountaintop. The cog railway, which was completed in 1869, was the first railway of its kind in the United States. Mount Washington also has hiking trails and a scenic roadway.

**Old Man of the Mountain, or Great Stone Face**, is a natural granite formation on Profile Mountain that looks like a side of an old man's face. It stands about 40 feet (12 meters) high, and is the state's official trademark. It was made famous by Nathaniel Hawthorne's short story "The Great Stone Face."

**Strawberry Banke**, in Portsmouth, is a restored colonial seaport. It features homes built in the 1700s and 1800s, craft shops, and historical exhibits.

**National forest and national historic site.** The White Mountain National Forest lies in north-central New Hampshire. Part of it extends into Maine. Saint-Gaudens National Historic Site, in Cornish, near Claremont, is the state's only national historic site. It includes the home, studio, and gardens of American sculptor Augustus Saint-Gaudens.

**State parks and forests.** New Hampshire has 44 state parks, 12 historic sites, and 118 state forests. Many parks have lakes and groves of stately trees, especially white birch. For information on the state parks, historic sites, and forests, write to Director, Division of Parks, Department of Resources and Economic Development, P.O. Box 1856, Concord, NH 03302.
Annual events

January-March
Winter Carnivals in Franconia, Hanover, Lincoln, Plymouth, and other communities (January and February); Ski races at all mountains (January through March); Annual Sandwich Notch Sled Dog Races in Center Sandwich (February); Annual World Championship Sled Dog Derby in Laconia (February).

April-June
Annual Sheep and Wool Festival in New Boston (May); Market Square Days Celebration in Portsmouth (mid-June).

July-December
Prescott Parks Art Festival in Portsmouth (July and August); League of New Hampshire Craftsmen’s Fair at Mount Sunapee State Park in Sunapee (August); Riverfest Celebration in Manchester (September); Annual New Hampshire Highland Games in Lincoln (mid-September); Fall Foliage Festival in Warner (October); Sandwich Fair (October); Candlelight Stroll at Strawbery Banke in Portsmouth (December); First Night New Hampshire in Concord, Keene, Portsmouth, and Wolfeboro (New Year’s Eve).
The Merrimack Valley extends northward from the Massachusetts border to central New Hampshire. It is named for the Merrimack River, which winds through the hilly, uneven valley. Large crops of hay and fruits grow in the rich soil between the hills. Many of the state’s chief mill and factory towns are in the valley.

The Hills and Lakes region surrounds the Merrimack Valley on the east, north, and west. It extends in a broad half-circle from Maine almost to the Vermont border. Most of New Hampshire’s large lakes nestle among forested hills in the region.

The White Mountains Region lies north of the Eastern New England Upland. It has rugged mountains separated by narrow river valleys. Spruce, fir, and yellow birch provide wood for New Hampshire’s paper mills.

The Mount Washington Observatory stands on top of New Hampshire’s highest peak. The observatory keeps daily records of weather conditions in the White Mountains.

*Manuel Dos Passos, Bruce Coleman Inc.*
and other wood products industries. The White Mountains attract summer and winter tourists.

An area of forest-covered hills in Coos County forms the northernmost part of the region. Lumbering and paper manufacturing are this area's chief industries. Dairy and potato farms thrive in the west.

**Coastline.** New Hampshire has a general coast along the Atlantic of only 13 miles (21 kilometers). This is the shortest coastline of any state bordering an ocean. Hampton, Rye, and other beaches lie along the shore. A group of islands called the Isles of Shoals lies 9 miles (14 kilometers) offshore. Four—Lunging, Seavey, Star, and White—belong to New Hampshire. The others are part of Maine.

**Mountains.** The Presidential Range of the White Mountains has the highest peaks in New England. Mount Washington is the highest mountain in this 86-peak range and reaches 6,288 feet (1,917 meters). Several other peaks in the Presidential Range are more than 1 mile (1.6 kilometers) high. These include Mount Adams, 5,798 feet (1,767 meters); Mount Jefferson, 5,715 feet (1,742 meters); Mount Clay, 5,532 feet (1,686 meters); Mount Monroe, 5,385 feet (1,641 meters); and Mount Madison, 5,363 feet (1,635 meters). The Franconia Range, also in the White Mountains, includes the famous Profile Mountain, a shoulder of Cannon Mountain. Each year, thousands of sightseers visit the area to view the remarkable Old Man of the Mountain (or Great Stone Face), a profile of an old man's face caused by a rock formation near the mountaintop.

New Hampshire's mountains include five monadnocks. A monadnock is made up of rock that did not wear down when all the land around it was leveled by erosion. The monadnocks and their heights are Mount Moosilauke, 4,810 feet (1,466 meters); Mount Monadnock, 3,165 feet (965 meters); Mount Cardigan, 3,121 feet (951 meters); Mount Kearsarge, 2,937 feet (895 meters); and Sunapee Mountain, 2,743 feet (836 meters).

**Rivers and lakes.** New Hampshire's chief rivers rise in the mountainous north. The Connecticut River begins near the Canadian border and flows generally southward. It separates New Hampshire and Vermont. After leaving New Hampshire, the 407-mile (655-kilometer) river cuts across Massachusetts and Connecticut and empties into Long Island Sound. The Pemigewasset River flows south from Franconia Notch. The Merrimack River is formed where the Pemigewasset meets the Winnipesaukee River at Franklin. The Merrimack flows south into Massachusetts. The Androscoggin and Saco rivers flow through northeastern New Hampshire, and then cross into Maine. The Piscataqua and Salmon Falls rivers, in the southeast, form part of the New Hampshire-Maine border and empty into Portsmouth Harbor.

### Average January temperatures

New Hampshire winters are cold with heavy snowfalls. Southeastern New Hampshire has the mildest temperatures.

### Average July temperatures

New Hampshire has cool summers with low humidity. The temperatures are warmer in the southern part of the state.

### Average yearly precipitation

Much of the state's precipitation comes as snow. The heaviest precipitation is in the south and far north of the state.
About 1,300 lakes lie scattered throughout New Hampshire's hills and mountains. The largest, Lake Winnipesaukee, covers about 70 square miles (180 square kilometers) and has many islands. Other lakes include Ossipee, Squam, Sunapee, Umbagog (partly in Maine), and Winnisquam.

**Plant and animal life.** Forests cover about 85 percent of New Hampshire. Valuable trees include ashes, basswoods, beeches, birches, cedars, elms, firs, hemlocks, maples, oaks, pines, spruces, and tamaracks. Shrubs and flowering plants thrive in the state's forests. Shrubs include American elders, blueberries, mountain laurel, and sumacs. Wildflowers, which grow throughout New Hampshire, include black-eyed Susans, daisies, fireweed, gentians, goldenrod, purple trillium, violets, and wild asters.

Deer, rabbits, foxes, mink, beavers, raccoons, squirrels, and chipmunks are common throughout New Hampshire. Black bears and moose live in the northern forests. Game birds include ruffed grouse, pheasants, woodcocks, ducks, and geese. Among the many birds that nest in the state are robins, bluebirds, purple finches, sparrows, and warblers.

New Hampshire's freshwater fish include brook, brown, lake, and rainbow trout; largemouth and smallmouth bass; and landlocked salmon, pickerel, perch, whitefish, and bullheads. Saltwater fish found in New Hampshire include bluefish, cod, cunner, cusk, flounder, haddock, hake, mackerel, pollock, striped bass, and tuna. The state's coastal waters have clams, lobster, oysters, and shrimp.

**Climate.** New Hampshire has cool summers with low humidity. In winter, heavy snow falls in much of the state. January temperatures average about 16 °F (−9 °C) in the north and about 22 °F (−6 °C) in the south. The state's lowest temperature, −47 °F (−44 °C), was recorded at Mount Washington on Jan. 29, 1934. July temperatures average about 66 °F (19 °C) in the north and 70 °F (21 °C) in the south. The state's highest temperature, 106 °F (41 °C), was recorded at Nashua on July 4, 1911.

New Hampshire gets about 42 inches (107 centimeters) of precipitation (rain, melted snow, and other moisture) a year. The state's average yearly snowfall ranges from about 50 inches (130 centimeters) near the Atlantic Ocean to over 100 inches (250 centimeters) in the north and west.

**Economy**

Service industries provide the largest portion of New Hampshire's gross state product—the total value of goods and services produced in a state in a year. Major activities within the service industries include education, health care, real estate, and retail trade. However, manufacturing is the state's single most important economic activity. New Hampshire's beautiful seacoast, lakes, mountains, and unspoiled wilderness attract many tourists. Tourist activities contribute billions of dollars a year to the state.

New Hampshire's low tax rates have attracted many new businesses and residents to the state. New Hampshire has no general sales or personal income taxes. Thousands of people who work in Massachusetts live in New Hampshire to take advantage of the low taxes.

**Natural resources.** New Hampshire's climate and soils support dense forests. Minerals are found in many areas of the state, but the mining output is small.

**Soil.** Rock and a thin layer of soil cover most of New Hampshire's hills and mountains. The soil in New Hampshire's valleys is chiefly clay and loam, and coarse gravel and sand. The clay and loam support farm crops. The gravel and sand supply low-cost roadbuilding material.

**Forests.** Forests cover about 85 percent of New Hampshire. Commercially valuable softwood trees include balsam fir, cedar, hemlock, spruce, tamarack, and white pine. Valuable hardwoods include ash, basswood, beech, birch, maple, and oak.

**Minerals.** New Hampshire's chief mined resources are its deposits of granite, and sand and gravel. Large quantities of gray, red, and other kinds of granite give New Hampshire the nickname of the Granite State.

**Service industries** account for the largest part of the gross state product of New Hampshire. These industries are located in towns and cities throughout the state, especially in Dower, Manchester, and Nashua.

New Hampshire's leading service industry, in terms of the gross state product, is finance, insurance, and real estate. The state's growing urban areas and tourist trade make real estate a major part of this industry. Manchester is New Hampshire's major insurance and banking center. Large holding companies are headquartered in Hampton and Nashua.

Community, business, and personal services rank second among New Hampshire's service industries. Community, business, and personal services employ more people than any other industry in the state. This industry group consists of a variety of establishments, including private health care, law firms, vacation resorts, and repair shops. The White Mountains and the lake and
coastal areas of New Hampshire have many resorts.

Wholesale and retail trade form the third-ranking service industry in terms of the gross state product. Distributors of automobiles and groceries are important parts of the wholesale trade sector. Major retail establishments include discount stores, food stores, service stations, and restaurants.

Government ranks fourth among service industries in New Hampshire. Government services include the operation of public schools and hospitals, and military establishments. Many people are employed by the public school system. The Portsmouth area is the home of the Portsmouth Naval Shipyard.

Transportation, communication, and utilities rank fifth among the state's service industries. Transportation is less important in New Hampshire than in many other states, because most of the population lives within a relatively small area. More information about transportation and communication appears later in this section.

Manufacturing. Goods manufactured in New Hampshire have a value added by manufacture of more than $11 billion a year. Value added by manufacture represents the increase in value of raw materials after they become finished products.

Computer and electronic products are the state's leading type of product in terms of value added by manufacture. Computers are the leading product in this sector. They are assembled in Hudson, Manchester, Nashua, Portsmouth, and Salem. Telephone equipment and computer microchips are also important. Nashua has a large plant that makes military communication systems.

Machinery ranks second in terms of value added.

Printing and metalworking machinery are among the leading machinery products. Other products from this area include ball bearings, machine tools, and equipment for making lenses and other optical instruments.

Other products made in New Hampshire include fabricated metal products, paper products, printed materials, and rubber and plastic products. Fabricated metal products are made in Laconia, Manchester, and Rochester. Paper mills are a major part of the economy in Coos County in the northern part of the state. New Hampshire's printed materials include business forms, magazines, and newspapers. Rubber and plastic products include shoes, belts and gaskets, and plastic films.

Agriculture. Farmland covers only 7 percent of New Hampshire. The state has approximately 2,900 farms.

Dairy farming is New Hampshire's most important agricultural activity. Dairy farms operate throughout the state, but they are especially numerous in the west along the Connecticut River. Other livestock products in New Hampshire include beef cattle, eggs, and hogs.

Hay, the state's leading field crop, is used mainly for cattle feed. Apples are New Hampshire's leading fruit crop. Potatoes and sweet corn are the most important vegetables. Other agricultural goods include greenhouse and nursery products and maple syrup. Many farms grow evergreens for use as Christmas trees.

Mining. Sand and gravel are the state's chief mined products. The leading areas for sand and gravel production are Hillsborough and Merrimack counties in the south-central part of the state. Sand and gravel are used to make roadbeds and concrete.

Building stone and crushed stone are also important mined products in New Hampshire. Several parts of the state have granite quarries. The Concord quarries, in Merrimack County, have supplied granite for many famous buildings in the United States.

Electric power. About 60 percent of New Hampshire's power needs are supplied by the Seabrook Nuclear Power plant, the state's only nuclear plant. About 25 percent is produced by coal-burning plants. Hydroelectric plants on the Connecticut River and petroleum-burning plants provide most of the rest of the state's electric power. The hydroelectric plants include Concord Dam near Monroe, Wilder Dam near Hanover, and the Samuel C. Moore Dam near Littleton.

Transportation. New Hampshire's first railroad began operating in 1838. Today, six rail lines provide freight service in the state. New Hampshire has no local commuter rail service. The state's largest airport is in Manchester. The airport provides flights to Boston, New York City, and several other cities.

Roads and highways in the state total about 15,000 miles (24,000 kilometers). The New Hampshire Turnpike parallels the seacoast. The Spaulding Turnpike extends the seacoast turnpike from Portsmouth to the Union area. The Everett Turnpike links Concord and Massachusetts. Interstate 93 connects Concord to Vermont.

Communication. About 45 newspapers are published in New Hampshire. Eight of these are dailies. The state's leading newspapers include Foster's Democrat of Dover, The Keene Sentinel, the Laconia Citizen, The

Economy of New Hampshire

This map shows the economic uses of land in New Hampshire and where the state's leading farm, mineral, and forest products are produced. Major manufacturing centers are shown in red.
at Laconia in 1922. The first television station, WMUR-TV, began operation at Manchester in 1954. New Hampshire now has six television stations and about 70 radio stations. Cable television systems and Internet providers serve many communities.

**Government**

**Constitution of New Hampshire** New Hampshire took effect in 1784. It replaced a temporary Constitution that had been adopted in 1776. Constitutional amendments may be proposed by a three-fifths vote of each house of the New Hampshire state legislature, or by a constitutional convention. To become law, a proposed constitutional amendment needs the approval of two-thirds of the people voting on the issue in an election. A majority of the members of both houses of the New Hampshire legislature may propose a constitutional convention. The proposal must be approved by two-thirds of the citizens voting on it. If no constitutional amendment is proposed, the question of holding a convention must be voted on by New Hampshire residents every 10 years.

**Executive.** The governor of New Hampshire holds office for a two-year term. A governor may be reelected any number of times.

The executive branch of the New Hampshire government is somewhat unusual. The state has no lieutenant governor. However, it does have an executive council, which is made up of five members. Members of the executive council are elected by the people to two-year terms. Most major executive officials appointed by the governor must be approved by the executive council.

The state governors of New Hampshire

*Democratic-Republican*  
†Also called the Know-Nothing Party.
These officials include the attorney general and the heads of many departments and commissions. The New Hampshire legislature elects the secretary of state and state treasurer to two-year terms.

Legislature is called the General Court. By law, it consists of a 24-member Senate and a 400-member House of Representatives. The U.S. House of Representatives is the only legislative body in the country with more members than the New Hampshire house. New Hampshire's towns and wards (divisions of cities) send from 11 to 11 legislators to the House of Representatives, depending on their populations. Representatives serve two-year terms. Voters in each of the 24 senatorial districts elect a senator to a two-year term. The senatorial districts are also based on population.

Legislative sessions begin the Wednesday after the first Tuesday of January. The state legislators receive a fixed salary of $200 for their two-year term. Their allowance for travel expenses covers 45 session days. Legislators are paid for 15 business days during special sessions of the General Court. The governor or the General Court can call special sessions of the New Hampshire legislature.

Courts. The Supreme Court of New Hampshire has a chief justice and four associate justices. The next lower court, the Superior Court, has a chief justice and 16 associates. A probate judge presides over each of the 10 probate courts, 1 in each county. The state also has municipal and district courts. The governor, with approval of the executive council, appoints all state and local judges. Judges may serve until they are 70 years old.

Local government in New Hampshire operates as one of the purest forms of democracy in the world. The state's 221 towns are nicknamed "little republics." They are so named because they have almost complete self-government. Each year, the voters assemble for a town meeting at which they can participate directly in governmental decisions. Voters elect town officials, approve budgets, and make decisions on other local business. The chief administrative officials at the town level are the selectmen. Most of the towns have three selectmen. Selectmen serve three-year terms. A few towns have abandoned or modified the traditional form of government by giving greater power to an elected council and, in some cases, to an appointed executive.

New Hampshire's 13 incorporated cities use either the mayor-council or city-manager form of government. The cities have home rule. That is, they are free to write and amend their own charters. Each of the state's 10 counties also has its own government. County officials include the sheriff, attorney, treasurer, register of deeds, register of probate, and county commissioners. These officials are elected to two-year terms.

Revenue. Taxes account for about half of the state government's general revenue (income). About a fifth comes from federal government grants and programs. Charges for government services are another important source of general revenue. New Hampshire collects no general sales or personal income taxes. Taxes on corporate income, motor fuels, motor vehicle licenses, and public utilities are the largest sources of tax revenue. A lottery helps finance public schools. But the state's contribution to schools is low, and towns and cities rely heavily on local property taxes to fund public schools.

Politics. New Hampshire became a Republican state shortly before the Civil War (1861-1865). Until 1850, the state usually voted Democratic. But most of New Hampshire's people opposed slavery and then became Republicans. Since 1856, Republicans have won most of the major elective offices in New Hampshire. However, Democratic strength has increased since the 1960s.

Republicans have won New Hampshire's electoral votes in about three-fourths of the presidential elections since 1856. For the state's electoral votes and its voting record in presidential elections, see Electoral College (table).

History

Indian days. About 5,000 Indians probably lived in what is now New Hampshire before the Europeans came. Most belonged to two branches of the Algonquian Indian family—the Abenaki and the Pennacook. The Abenaki branch included the Ossipee and the Pequawket tribes. The Pennacook included the Amoskeag, Nashua, Piscataqua, Souhegan, and Squamscot tribes. New Hampshire Indians built wigwams of bark and skins. They hunted and fished, and farmed small fields of corn. The tribes lived together in peace, but often wondered against their common enemy, the Iroquois.

Exploration. No one knows who were the first European settlers to reach New Hampshire. But wide-scale exploration of the area began in the early 1600s. In 1603, Martin Pring of England sailed a trading ship up the Piscataqua River. Pring and his crew may have landed in Portsmouth. The French explorer Samuel de Champlain landed on the New Hampshire coast in 1605. In 1614, the English captain John Smith reached the Isles of Shoals. He named them Smith's Isles.

Settlement. In 1619, England's King James I founded the Council for New England to encourage American settlement. The council granted David Thomson land in present-day New Hampshire. In 1623, Thomson and his followers settled at Odiorne's Point (now a part of Rye). Edward Hilton settled Hilton's Point (now Dover) in the 1620s. Some historians believe these settlements began at the same time. Others think Hilton's began later. Other early settlements include Strawbery Banke (now Portsmouth), established in 1630; and Exeter and Hampton, founded in 1638.

In 1622, the Council for New England gave John Mason and Sir Ferdinando Gorges a large tract of land in present-day New Hampshire and Maine. In 1629, the land was divided between the two men. In 1634, Mason and Gorges gained more land in the area. Mason called his land New Hampshire, after his native county, Hampshire, England. New Hampshire was made part of Massachusetts in 1641. But in 1680, King Charles II of England made New Hampshire a separate province. The king appointed John Cutt as New Hampshire's first provincial governor (then called president).

French and Indian wars were fought in New Hampshire and the rest of New England off and on from 1689
John Smith reached the Isles of Shoals off the coast of present-day New Hampshire in 1614. He named them Smith's Isles.

Robert Rogers of New Hampshire led a group of daring soldiers called Rogers's Rangers during the French and Indian War.

New Hampshire minutemen hurried to Boston to fight the British in 1775 after the Revolutionary War broke out in Massachusetts.

The Portsmouth Naval Shipyard was established in 1800. The shipyard built warships during World War I and specialized in constructing submarines during World War II.

Alan B. Shepard, Jr., in 1961 became the first American to travel in space. Shepard was born in East Derry.

Important dates in New Hampshire

1603 Martin Pring of England explored the mouth of the Piscataqua River.
1614 Captain John Smith of England landed on the Isles of Shoals.
1620s David Thomson and Edward Hilton made the first permanent settlements in New Hampshire.
1641 The Massachusetts Colony gained control of New Hampshire.
1680 New Hampshire became a separate royal colony.
1776 New Hampshire broke away from Britain and adopted a temporary constitution.
1784 New Hampshire adopted its present constitution.
1788 New Hampshire became the ninth state when it ratified the U.S. Constitution on June 21.
1833 Franklin Pierce of Hillsboro became the 14th President of the United States.
1944 The International Monetary Conference was held at Bretton Woods.
1961 Alan B. Shepard, Jr., of East Derry became the first American to travel in space.
1964 The New Hampshire sweepstakes lottery began. It was the first legal U.S. lottery since the 1890s.
1986 Christa McAuliffe, a Concord teacher, was among the seven crew members killed when the space shuttle Challenger broke apart shortly after take-off.
1996 Jeanne Shaheen, a Democrat, became the first woman to be elected governor of New Hampshire.
to 1763. The French and their Indian allies battled to gain control of the area from the British. Guided by Indians, French forces pushed down from Canada. Robert Rogers, the leader of a group of soldiers called Rogers's Rangers, and John Stark, both of New Hampshire, won fame as colonial military leaders during this period. See French and Indian wars.

Colonial New Hampshire was a rural society. Most of the people kept busy clearing the wilderness, building houses, and growing food. In 1767, when New Hampshire took its first census, the colony had 52,700 people. The king of England appointed the governor and governor's council. But the people elected assemblymen to represent them in colonial affairs.

The Revolutionary War. During the 1760's, the United Kingdom passed a series of laws that caused unrest in New Hampshire and the other American colonies. Most of these laws either imposed severe taxes or restricted colonial trade. In December 1774, Paul Revere rode to New Hampshire to warn of a British military build-up in Massachusetts. A band of New Hampshire residents, led by John Sullivan, seized military supplies from a British fort in New Castle. This was one of the first armed actions by colonists against the British.

After the Revolutionary War broke out in Massachusetts in 1775, hundreds of New Hampshire "minutemen" hurried to Boston to fight the British. New Hampshire was the only one of the 13 original colonies in which no actual fighting occurred.

New Hampshire became the first colony to form a government wholly independent of the United Kingdom. It did so on Jan. 5, 1776, when it adopted a temporary constitution. On July 9, 1778, New Hampshire ratified the Articles of Confederation (the forerunner of the United States Constitution). On June 21, 1788, New Hampshire became the ninth state to ratify the U.S. Constitution. New Hampshire's ratification put the Constitution into effect.

The 1800's. New Hampshire remained an agricultural state from 1800 until the outbreak of the American Civil War in 1861. But it began an industrial growth that has continued to the present day. Manchester, the largest industrial center, became the state's first incorporated city in 1846. Portsmouth developed as a leading clipper-ship port in the early 1800's, and the first railroad opened in 1838. During the 1850's, business leaders built hosiery plants, woolen mills, and factories that made boots and shoes, machine tools, and wood products.

Several people from New Hampshire gained national fame during this period. They included Franklin Pierce, the 14th president of the United States, and Daniel Webster, a leading orator and U.S. senator.

New Hampshire was a leading opponent of slavery. About 34,000 state residents served with the Union forces during the Civil War, and the Portsmouth Naval Shipyard built ships that blocked Southern ports.

Industrial development increased greatly after the Civil War ended in 1865. The textile, woodworking, and leather industries were among those that grew at record rates. Thousands of French-Canadian and European immigrants came to New Hampshire to fill the labor needs caused by expansion of mills and factories. At the same time, many farmers left the state to claim free land in the West. Farming activity decreased in New Hampshire as industry grew.

The early 1900's. During World War I (1914-1918), the Portsmouth Naval Shipyard built warships. New Hampshire's cotton and woolen textile industries declined in the 1920's. Leather and shoe manufacturing became the state's leading industry. New Hampshire improved its highway system during the 1920's, and private utility companies built hydroelectric plants in the state. The Great Depression of the 1930's slowed the growth of the state's economy. Conditions improved after the Depression eased in the late 1930's.

The mid-1900's. During World War II (1939-1945), Portsmouth built submarines and repaired warships, and New Hampshire's textile mills supplied materials for military uniforms. These economic activities helped end depression conditions. In 1944, representatives of 44 na-

---

The International Monetary Conference was held in 1944 at Bretton Woods. Representatives from 44 nations made plans to restore world trade after World War II. They also drew up the plans for two United Nations agencies—the International Monetary Fund and the World Bank.
New Hampshire became increasingly urban and industrial during the mid-1900s. In the 1950s, the state approved the formation of a Business Development Corporation and established an Industrial Park Authority. These two agencies worked to aid new businesses. They also tried to attract industry to New Hampshire.

New Hampshire's once important shoe industry declined sharply because of competition from other states and other countries, especially Italy. But the rapid growth of New Hampshire's electronics industry more than made up for losses in the shoe industry.

In 1961, Alan B. Shepard, Jr., of East Derry became the first American to travel in space. John W. King, a Democrat, served as governor from 1963 to 1969. King was only the third Democrat since 1875 to serve as governor.

In 1963, New Hampshire adopted the first legal lottery in the United States since the 1890s. The lottery is called a sweepstakes. The state uses the profits from the sweepstakes to help pay for public education. The first sweepstakes were held in September 1964.

Recent developments. Christa McAuliffe, a Concord high school teacher, was chosen to be the first "ordinary citizen" in space. She was among the seven crew members killed when the space shuttle Challenger broke apart shortly after take-off on Jan. 28, 1986.

New Hampshire today is one of the few states that does not collect a general individual income tax or a general sales tax. This low-tax policy helps attract new industries and other businesses to the state. But low taxes result in less money to pay for state-funded programs and services and for aid to local communities.

During most of the 1980s, New Hampshire experienced economic prosperity and rapid population growth, especially in the southern part of the state. In the late 1980s and early 1990s, however, a national recession resulted in the loss of many jobs, particularly in the areas of real estate, banking, and the defense industry. The state's economy improved in the mid-1990s.

The University of New Hampshire in Durham is part of a state-supported system of higher education. Thompson Hall, shown here, serves as the university's administration building.

New Hampshire, University of, is a state-supported coeducational system of higher education. The official name of the system is the University System of New Hampshire. The system includes the main campus of the University of New Hampshire in Durham, another campus in Manchester, state colleges in Keene and Plymouth, and the School for Lifelong Learning, which offers older students degrees at centers throughout New Hampshire.

The Durham campus has colleges of engineering and physical sciences, liberal arts, and life sciences and agriculture. It also has a school of health and human services, a school of business and economics, a graduate school, and a two-year school of applied science. The Durham campus grants bachelor's, master's, and doctor's degrees. The Manchester campus offers bachelor's degrees. The Keene and Plymouth campuses grant bachelor's and master's degrees.

The university was founded in 1866 as the New Hampshire College of Agriculture and Mechanic Arts. It became the University of New Hampshire in 1923.

Critically reviewed by the University System of New Hampshire

New Harmony, Indiana (pop. 916), became famous as an educational and cultural center during the 1820s. Today, this quiet town in Posey County is a trading center for a farming region in the lower Wabash River Valley (see Indiana [map]).

George Rapp (1757-1847), the leader of a religious group called Harmonists, founded the village of Harmony in 1814. Rapp brought the Harmonists from the kingdom of Wiirttemberg in Germany to escape religious persecution. They spent 10 years in Butler County, Pennsylvania, before migrating to Indiana. The Harmonists were celibate and could not own property. In 1824, Rapp led his followers back to Pennsylvania and founded the village of Economy, which is now called Ambridge. The society died out there near the end of the 1800s.

Robert Owen, a wealthy social reformer and industrialist from Scotland, purchased the Harmonists' Indiana town in 1825. He renamed it New Harmony and attracted new residents with the promise of an earthly utopia (perfect society). Owen established a social order based on community ownership and equality of work and profit. His partner was William Maclure, a wealthy...
scientist from Philadelphia who is sometimes called the "Father of American Geology." In the 1820's, Maclure sent the first seed for the Chinese golden-rain trees to Thomas Say, a geologist in New Harmony. These golden-rain, or gate, trees now line the streets of the town. The experiment in community living made New Harmony famous. Scientists and scholars flocked to the town. But few of the 1,000 or more Owenites understood the principles of the experiment, and they split into several factions. By 1827, Owen's plan had failed. New Harmony remained an educational, scientific, and cultural center until the American Civil War (1861-1865). The Minerva Club, the first woman's club to have a constitution and bylaws, was organized at New Harmony in 1859. Some of the buildings erected by the Harmonists and Owenites have been restored. David L. Anderson See also Indiana (Schools: Places to visit): Owen, Robert; Owen, Robert Dale.

**New Haven** (pop. 123,626) is the home of Yale University and the second largest city in Connecticut. Only Bridgeport has a larger population.

**The city.** A mayor and board of aldermen govern New Haven. The city lies on the northern shore of Long Island Sound (see Connecticut [political map]). Its bay is 4 miles (6.4 kilometers) long and 2 miles (3.2 kilometers) wide. Three small rivers, the Mill, Quinnipiac, and West, flow into the bay. At the northern border of the city stand two impressive rock hills—West Rock, rising 670 feet (204 meters), and East Rock, 359 feet (109 meters). The historic downtown Green lies at the center of New Haven. Three churches built in the 1810's stand along one side of the Green. The Yale campus lies to the north and west of the Green and covers about 175 acres (71 hectares). Offices and City Hall and other government buildings line the other sides of the Green.

A memorial in front of City Hall marks the site of the jail where the black slaves who rebelled on the ship La Amistad were held during their trial (see Amistad Rebellion). New Haven is now the home port for a life-sized replica of La Amistad.

**Economy.** Yale University and the Southern New England Telephone Company are the city's largest employers. The Knights of Columbus, a Roman Catholic organization that is a major insurance provider, has its national headquarters in New Haven. The city's factories produce car radiators, cardboard boxes, electrical wire, hardware tools, lingerie, and sporting firearms.

**Cultural life and recreation.** Yale University, founded in 1701, is one of the oldest institutions of higher learning in the United States (see Yale University). Other New Haven colleges include Albertus Magnus College and Southern Connecticut State University.

The city's cultural attractions include the Peabody Museum of Natural History, the Eli Whitney Museum, the Yale Center for British Art, the Yale University Art Gallery, and the Beinecke Rare Book and Manuscript Library. New Haven is the home of the Connecticut Chamber Orchestra and the New Haven Symphony Orchestra, one of the oldest symphony orchestras in the nation. The city's theaters include the Long Wharf Theater, the Yale Repertory Theatre, and the Shubert Performing Arts Center. Yale's football team plays in the Yale Bowl.

**History.** The Quinnipiac Indians originally inhabited the area. Adriaen Block, a Dutch explorer, visited the harbor in 1614. A group of English Puritans led by Theophilus Eaton and John Davenport founded a town there in 1638. At first, they called it Quinnipiac (Long River Place) after the original Indian village. In 1640, they changed the town's name to New Haven, after the English city of Newhaven. In 1784, New Haven became a city. Its first mayor was political leader and judge Roger Sherman (see Sherman, Roger). New Haven and Hartford were twin capitals of Connecticut from 1701 until 1875, when Hartford became the sole capital.

During the 1700's and early 1800's, New Haven's business centered on its port. During the 1800's, the city became an industrial center. The growth of Yale University also contributed to the area's development. Renewal projects in the late 1900's included the Audubon Arts Center complex and Wooster Square. Once a run-down area, Wooster Square now includes a historic district and commercial and industrial buildings. Stephen Fagin

**New Hebrides Islands.** See Vanuatu.

**New Holland.** See Australia (History).

**New Ireland** is the second largest of the more than 200 islands of the Bismarck Archipelago, which forms part of the nation of Papua New Guinea. Only New Britain is larger than New Ireland in the island group. New Ireland is about 230 miles (370 kilometers) long and covers about 3,340 square miles (8,651 square kilometers) in the southwest Pacific (see Papua New Guinea [map]). It has about 87,000 people. Mountains cover much of the island, and coral reefs surround it. David A. M. Lea
Atlantic City is a world-famous New Jersey resort. Hotels, gambling casinos, restaurants, shops, and beaches line the Atlantic City Boardwalk. New Jersey has many beautiful vacation areas along the Atlantic seaboard that attract millions of visitors to the state each year.

New Jersey  The Garden State

New Jersey is a state of industrial cities and towns, glistening beaches, and popular summer resorts. It is the fifth smallest state of the United States. Only Hawaii, Connecticut, Delaware, and Rhode Island have a smaller area. But New Jersey ranks ninth in population among the states, and few states manufacture more products or attract more vacationers.

New Jersey is the most densely populated state. All of New Jersey's people live in one of the state's nine metropolitan areas. The state's cities include such busy manufacturing centers as Camden, Elizabeth, Jersey City, Newark, Paterson, and Trenton. However, New Jersey also has many small, quiet towns. A large number of these towns are the homes of people who work in New York City or Philadelphia. Both of these giant cities are neighbors of New Jersey.

New Jersey's location gives it great economic importance. The state lies between the Hudson and Delaware rivers, and between New York City and Philadelphia. Miles of wharves stretch along the New Jersey side of the Hudson. Ocean liners, freighters, and other ships from all parts of the world dock there and along the Delaware.

Products made in New Jersey are used throughout the United States and in many other parts of the world. They find giant nearby markets in New York City and Philadelphia. New Jersey is one of the leading states in the production of chemical and pharmaceutical products. The state's other leading manufactures include electronics and food products.

Service industries are an important part of the New Jersey economy. Many of the state's workers are employed in such activities as education, health care, and retail trade, especially in northeastern New Jersey.

New Jersey's vacation areas along the Atlantic Coast contrast sharply with the state's industrial cities. More than 50 resort cities and towns, including Atlantic City, Ocean City, and Cape May, line the New Jersey coast. The resort communities provide a wide variety of recreation activities for vacationers. Atlantic City's gambling casinos attract many visitors.

New Jersey and its people have played important roles in United States history. The state earned the nick-
A scenic mill stands in Clinton, a rural town in northwestern New Jersey. Despite its small size and large population, the state has many small, quiet towns.

name Cockpit of the Revolution because of the many battles fought on its soil during the Revolutionary War. American patriots and British redcoats clashed nearly a hundred times in New Jersey. People compared these actions with cockfights. General George Washington turned the tide of the war at Trenton in 1776 when he led his tattered army across the Delaware River and surprised the enemy. Trenton and Princeton each served as the nation's capital during the 1780s.

In 1884, Grover Cleveland of New Jersey was elected the 22nd President of the United States. He was elected President again in 1892. Woodrow Wilson served as president of Princeton University and governor of New Jersey before he was elected the 28th President in 1912. Wilson was reelected in 1916, and led the nation through World War I.

Three of the world's greatest scientists and inventors worked in New Jersey for many years. Thomas Edison invented the electric light and the phonograph in his laboratory in Menlo Park. Samuel F. B. Morse developed the first successful U.S. electric telegraph near Morris-town. Albert Einstein worked many years at the Institute for Advanced Study in Princeton.

New Jersey's many truck farms, orchards, and flower gardens give it the nickname of the Garden State. Trenton is the capital of New Jersey and Newark is the largest city in the state.

Interesting facts about New Jersey

The first drive-in motion picture theater was opened on June 6, 1933, on Crescent Boulevard outside Camden. The theater presented two shows each night on a 40 by 50 foot (12 by 15 meter) screen. Inclined rows at the theater accommodated 500 cars. Richard Hollingshead, Jr., the owner of the theater, originated the idea for the drive-in.

First drive-in theater

A huge clock in a riverfront park in Jersey City can be read from across the Hudson River in New York City. The clock, which came from the old Colgate-Palmolive building, is 50 feet (15 meters) across. The minute hand, about 26 feet (8 meters) long, moves 1 mile (1.6 kilometers) every 4 minutes.

The first electric sewing machine was made in 1889 by the Singer Manufacturing Company at its factory in Elizabethport (now Elizabeth).

Newark, New Jersey's largest city, is the center of a large industrial area in the northeastern part of the state. Newark ranks as one of the nation's leading manufacturing centers.
Symbols of New Jersey
The state flag, adopted in 1896, bears a version of the state seal. On the seal, adopted in 1928, three plows on a shield represent agriculture. A helmet symbolizing sovereignty and a crest with a horse's head appear above the shield. Supporting the shield are Liberty, left, and Ceres, right, the Roman goddess of grain and a symbol of abundance.

New Jersey (brown) ranks 46th in size among all the states and is the smallest of the Middle Atlantic States (yellow).

General information
Statehood: Dec. 18, 1787, the third state.
State abbreviations: NJ (traditional); NJ (postal).
State motto: Liberty and Prosperity.
State song: none.

The State Capitol is in Trenton, the capital since 1790. Perth Amboy and Burlington served as twin capitals from 1703 to 1775. There was no definite capital from 1775 to 1790.

Land and climate
Area: 7,790 mi² (20,175 km²), including 371 mi² (960 km²) of inland water but excluding 425 mi² (1,102 km²) of coastal water.
Elevation: Highest—High Point, 1,803 ft (550 m) above sea level. Lowest—sea level along the Atlantic Ocean.
Costline: 130 mi (209 km).
Record high temperature: 110 °F (43 °C) at Runyon on July 10, 1936.
Record low temperature: −34 °F (−37 °C) at River Vale on Jan. 5, 1904.
Average July temperature: 75 °F (24 °C).
Average January temperature: 31 °F (−1 °C).
Average yearly precipitation: 45 in (114 cm).

Important dates
1524 Giovanni da Verrazzano explored the New Jersey coast.
1660 New Jersey became the 3rd state when it ratified the U.S. Constitution on December 18.
1776
1787 New Jersey adopted its first constitution.

**Population**

- **Population**: 8,414,350 (2000 census)
- **Rank among the states**: 9th
- **Population density**: 1,080 per mi² (417 per km²), U.S. average 78 per mi² (30 per km²)
- **Distribution**: 89 percent urban, 11 percent rural

**Largest cities in New Jersey**

- Newark: 273,546
- Jersey City: 240,055
- Paterson: 149,222
- Elizabeth: 120,568
- Edison: 97,687
- Woodbridge: 97,903
- Trenton: 84,143

**Economy**

**Chief products**

- **Agriculture**: greenhouse and nursery products, milk.
- **Manufacturing**: chemicals, computer and electronic products, food products, fabricated metal products, plastics and rubber products, printed materials, machinery.
- **Mining**: crushed stone, sand and gravel.

**Gross state product**

Value of goods and services produced in 1998: $319,201,000,000. Services include community, business, and personal services; finance; government; trade; and transportation, communication, and utilities. Industry includes construction, manufacturing, and mining. Agriculture includes agriculture, fishing, and forestry.

**Government**

**State government**

- Governor: 4-year term
- State senators: 40; 2- or 4-year terms
- Members of the General Assembly: 80; 2-year terms
- Counties: 21

**Federal government**

- United States senators: 2
- United States representatives: 13
- Electoral votes: 15

For information about tourism, write to: New Jersey Commerce and Economic Growth Commission, Office of Travel and Tourism, 20 W. State Street, P.O. Box 820, Trenton, NJ 08625-0820. The Web site at www.state.nj.us/travel also provides information.

For information on the economy, write to: New Jersey Council of Economic Advisors, P.O. Box 269, Trenton, NJ 08639-0269. The state's official Web site at www.state.nj.us also provides a gateway to much information on New Jersey's economy, government, and history.

**Timeline**

- 1858: First dinosaur skeleton discovered in North America was found buried in Haddonfield.
- 1879: Thomas A. Edison invented the electric light in Menlo Park.
- 1969: Casino gambling began in Atlantic City.
- 1978: The state's voters approved a lottery to raise money for state government and for education.
- 1987: New Jersey celebrated the bicentennial of its statehood.
People

Population. The 2000 United States census reported that New Jersey had 8,414,350 people. The population of New Jersey had increased 9 percent over the 1990 census figure, 7,730,188. According to the 2000 United States census, New Jersey ranks ninth in population among the 50 states.

All of the people in New Jersey live in metropolitan areas (see Metropolitan area). Nine metropolitan areas lie either partly or entirely in New Jersey. The metropolitan areas are Atlantic-Cape May, Bergen-Passaic, Jersey City, Middlesex-Somerset-Hunterdon, Monmouth-Ocean, Newark, Philadelphia (Pennsylvania), Trenton, and Vineland-Milleville-Bridgeton. For the populations of these metropolitan areas, see the Index to the political map of New Jersey.

Six metropolitan areas in the northern part of New Jersey, together with four metropolitan areas in New York and five in southwestern Connecticut make up a consolidated metropolitan area. The New York-Northern New Jersey-Long Island Consolidated Metropolitan Statistical Area has a population of about 21 million.

Newark is New Jersey's largest city, with a population of about 274,000. The state's other cities with more than 75,000 people, in order of population, include Jersey City; Paterson; Elizabeth; Trenton, the state capital; and Camden.

Population density
New Jersey is the most densely populated state. A majority of its people live in the northeast. The most thinly populated areas are in the northwest and the south.

A roadside farmstand in Belle Mead sells flowers and produce. New Jersey's many truck farms, flower gardens, and orchards earn it the nickname the Garden State.

Workers harvest cranberries from a bog near Chatsworth. New Jersey ranks as a leading cranberry-growing state. Farmers there also grow blueberries and peaches.

The Cape May Mall has many quaint shops and restaurants. Cape May, one of New Jersey's most popular seaside resorts, is located at the southern tip of the state.
New Jersey's largest population groups include people of Italian, Irish, German, and English descent. About 14 out of every 100 of New Jersey's people are African Americans. Hispanic Americans account for about 13 percent of the population, while Asians make up about 6 percent.

Schools. Colonial New Jersey had no public schools. Children attended school only if their parents could pay tuition. A public school system began in 1817, when the Legislature established a permanent school fund. A state commissioner of education and a 13-member State Board of Education direct the state's public school system. The governor, with the Senate's approval, appoints the board members to six-year terms. The governor appoints the commissioner to a term that coincides with his or her own. The Legislature is responsible for education, but it delegates administrative responsibilities to local school boards. The Commission on Higher Education directs New Jersey's public college system. New Jersey law requires children from age 6 through 15 to attend school. For the number of students and teachers in New Jersey, see Education (table). Two of the oldest U.S. universities and colleges are in New Jersey. They are Princeton University (1746) and Rutgers, the State University of New Jersey (1766).

Libraries. Thomas Cadwalader founded New Jersey's first public library at Trenton in 1750. The State Library in Trenton has large law and general reference collections that serve state government officials and are open to the public. The New Jersey Library Network includes many member libraries of all types, organized into regions. Member libraries can call on major libraries in each region for reference and interlibrary loan services. Libraries at Princeton and Rutgers universities have the largest collections among the state's colleges. The Harvey S. Firestone Memorial Library of Princeton University is New Jersey's largest research library.

Museums. The New Jersey State Museum in Trenton features archaeology, decorative arts, fine arts, and natural history exhibits. It includes an auditorium, exhibition halls, and a planetarium. The Newark Museum includes a planetarium and art, science, and natural history exhibits. The Liberty Science Center in Jersey City features exhibits on inventions and health. The Montclair Art Museum and Princeton University Art Museum display excellent collections of paintings and sculpture.

### Universities and colleges

This table lists the universities and colleges in New Jersey that grant bachelor's or advanced degrees and are accredited by the Middle States Association of Colleges and Schools.

New Jersey is one of the great coastal playgrounds of the United States. Every year, millions of vacationers flock to the state’s seaside resorts. They swim in the Atlantic Ocean, sunbathe on sandy beaches, and stroll along boardwalks lined with shops and museums. Visitors also enjoy many historic sites in the state.

New Jersey attracts many people who enjoy outdoor sports. They can catch game fish in the ocean or cast for trout in stocked streams. Hunters shoot ducks in coastal areas, and deer, pheasants, and rabbits on inland shooting grounds. Sailing is popular in the coastal bays. The state also has fine ski areas and golf courses.

The Miss America Pageant, held each September or October in Atlantic City’s Convention Center, is New Jersey’s best-known annual event. This nationally televised pageant features women from every state.

Rutgers University Trial Gardens in New Brunswick

Places to visit

Following are brief descriptions of some of New Jersey’s many interesting places to visit:

**Barneget Lighthouse**, near Barneget Light, is a favorite subject of painters and photographers. The lighthouse is part of a state park that also includes a museum and a sandy beach.

**Delaware Water Gap** is a deep narrow gorge formed where the Delaware River cuts through the Kittatinny Mountains. This scenic gap separates New Jersey and Pennsylvania north of Columbia, New Jersey, and forms part of the Delaware Water Gap National Recreation Area.

**Monmouth Battlefield State Park**, near Freehold, is the site of the Battle of Monmouth, the last major battle in the North during the Revolutionary War in America (1775-1783).

**New Jersey State Aquarium**, in Camden, features a tank with many kinds of fish, a seal pool, and a trout stream.

**Princeton** is the home of Princeton University and Princeton Battlefield, the site of an important colonial victory in the Revolutionary War in America. The university’s Nassau Hall served as the U.S. Capitol in 1783.

**Seaside resorts** include Cape May, Ocean City, Seaside Heights, and the Wildwoods. Atlantic City’s boardwalk was the first built in the United States. In addition, the resort has a convention center for major events. Many visitors are attracted by Atlantic City’s gambling casinos. Cape May, the oldest resort in the United States, has over 250 Victorian buildings.

**Trenton** has many points of interest, including the New Jersey State Museum, the State Capitol, and the Old Barracks, used by British soldiers during the French and Indian wars (1669-1763) and by the Hessians at the Battle of Trenton (1776).

**Waterloo Village**, in Stanhope, is a restored village of the 1700s. The village includes a grist mill, blacksmith shops, and many furnished homes.

**National park and historic site**. Morristown National Historical Park, established in 1933, lies in and near Morristown. It includes Ford Mansion, George Washington’s headquarters during the winter of 1779-1780; Fort Nonsense, a restoration of a fort built in 1777; and several camps used by American soldiers during the Revolutionary War. See National Park System (table: National historical parks). The Edison National Historic Site in West Orange includes Thomas A. Edison’s home, laboratories, library, and models of his inventions.

**State parks and forests**. New Jersey has 40 state parks and 11 state forests. Liberty State Park, near the Statue of Liberty and Ellis Island, offers an excellent view of New York City’s skyline. The park also has a science museum with interactive exhibits. For information on New Jersey’s state parks, write to Division of Parks and Forestry, P.O. Box 404, Trenton, NJ 08625. New Jersey and New York together maintain Palisades Interstate Park.
Annual events

January-March
Super Science Weekend in Trenton (January); Classic Car Auction, Flea Market, and Antique Show in Atlantic City (February); Sail Expo in Atlantic City (February and March).

April-July
Annual Shad Festival in Lambertville (April); Cherry Blossom Display in Newark (April); Annual Battle of Monmouth in Manalapan (June); First Union Bicycle Race in Trenton (early June); New Jersey Seafood Festival in Belmar (June); Opera Festival in Princeton (June-July); Pathmark Women's Professional Tennis Classic in Mahwah (July); New Jersey Offshore Grand Prix Ocean Races in Point Pleasant (July); New Jersey Shuffleboard Championships in Ocean City (July); Whitesbog Blueberry Festival in Browns Mills (July); New Jersey Festival of Ballooning in Readington (July).

August-September
Hummingbird Extravaganza in Swainton (August); Sussex Country Farm and Horse Show in Sussex (August); Baby Parades in Avalon, Ocean City, Sea Isle City, and Wildwood (August); Miss America Pageant in Atlantic City (September or October).

October-December
Victorian Week in Cape May (October); Cranberry Festival in Chatsworth (October); Grand Christmas Exhibition in Wheaton Village (November and December); Reenactment of Washington's Crossing of the Delaware in Titusville (December 25); Victorian Christmas Celebration in Cape May (December).
Land regions. New Jersey has four main land regions. They are, from northwest to southeast: (1) the Appalachian Ridge and Valley Region, (2) the New England Upland, (3) the Piedmont, and (4) the Atlantic Coastal Plain.

The Appalachian Ridge and Valley Region is a mountainous area in the northeastern corner of the state. It is part of a large region of the same name that runs from New York to Alabama. In New Jersey, it includes the Kittatinny Mountains and several valleys. The Kittatinny Mountains run parallel to New Jersey's northeastern border. The Delaware Water Gap, which is formed where the Delaware River cuts through the mountains, is one of the most scenic areas in the East. The Appalachian Valley lies southeast of the Kittatinny Mountains. This wide valley is part of the larger Great Valley. Shale and limestone formations lie in various parts of the Appalachian Valley. Herds of dairy cattle graze on grassy slopes in the valley, and farmers there raise apples and vegetables.

The New England Upland, usually called the Highlands, lies southeast of the Appalachian Ridge and Valley Region. The region extends into New York and Pennsylvania. Flat-topped ridges of hard rock, called gneiss, cover much of the New England Upland in New Jersey. Many lakes nestle among the ridges of the New England Upland in New Jersey. These lakes are among the state's most important tourist attractions.

The Piedmont crosses northern New Jersey in a belt 20 miles (32 kilometers) wide southeast of the New England Upland. The Piedmont covers an area from New York to Alabama. It covers only about a fifth of New Jersey, but about three-fifths of the state's people live there. The region includes such large industrial cities as Elizabeth, Jersey City, Newark, and Paterson. The cities of the Piedmont region owe much of their industrial importance to the many large rivers in the area. These rivers include the Hudson, the Passaic, the Ramapo, and the Raritan.

The Atlantic Coastal Plain is a gently-rolling lowland that covers the southern three-fifths of New Jersey. It is part of a plain with the same name that stretches from New York to Florida. In New Jersey, more than half the plain lies less than 100 feet (30 meters) above sea level. In the west and southwest, fertile soil supports many truck farms. Camden, Trenton, and other cities lie along the wide Delaware River in the western part of the plain. To the east, pine forests and salt marshes cover much of the Atlantic Coastal Plain. For this reason, large areas of the region are thinly populated. Salt marshes, shallow lagoons, and meadows lie near New Jersey's Atlantic coast. Over 50 resort cities and towns, including Atlantic City, Ocean City, and Cape May, lie on the eastern edge of the Atlantic Coastal Plain.

</table>

A herd of dairy cattle grazes on a pasture in the Appalachian Ridge and Valley Region of northwestern New Jersey. This area includes the Kittatinny Mountains and several valleys.
Coastline. A long, narrow sandbar makes up most of New Jersey's 130-mile (209-kilometer) coastline. Many inlets break the coast and lead to bays between the sandbar and the mainland. New Jersey's coastal bays include, from south to north, Great Egg Bay, Great Bay, Little Egg Harbor, Barnegat Bay, Sandy Hook Bay, Raritan Bay, and Newark Bay.

Mountains. New Jersey's most mountainous area is in the northwest. High Point, the state's highest peak, has an elevation of 1,803 feet (550 meters). It is in the Kittatinny Mountains in the Appalachian Ridge and Valley Region. The New Jersey Highlands, in the New England Upland Region, has mountains averaging more than 1,000 feet (305 meters). Other ranges in New Jersey include the Sourland and Watchung mountains, which generally rise about 450 feet (137 meters) in the Piedmont Region.

Rivers and lakes. New Jersey's most important rivers are the Delaware and the Hudson. The Delaware forms the state's western border and empties into Delaware Bay. The Hudson separates New Jersey and New York in the northeast and flows into the Atlantic Ocean. The Raritan is the longest river entirely within New Jersey. It flows about 75 miles (121 kilometers) through the north. Other important rivers in the north include the Hackensack, Millstone, Musconetcong, and Passaic. Southern New Jersey rivers include Great Egg Harbor, Maurice, Mullica, and Toms.

New Jersey has more than 800 lakes and ponds, mostly in the north. Lake Hopatcong is the state's largest lake. Other large lakes include Budd, Culvers, Green Pond, Greenwood (partly in New York), Lake Mohawk, and Swartswood.

Average January temperatures
New Jersey has cold winters. Temperatures are coldest in the north and mildest in the southern tip of the state.

Average July temperatures
Breezes from the Atlantic Ocean cool the coast in summer. The western part of the state has the hottest temperatures.

Average yearly precipitation
New Jersey has a fairly even amount of precipitation, but the north gets much more annual snowfall than the south.

Plant and animal life. Forests cover about two-fifths of New Jersey. Beech, birch, maple, oak, sweet gums, yellow poplar, and other hardwoods are the most valuable trees in the northern part of the state. Important trees of southern New Jersey include cedar, pitch pine, and short-leaf pine. The purple violet, the state flower, grows in wooded areas throughout the state. Honey-suckle, goldenrod, and Queen Anne's lace grow in many areas. Other flowers found in New Jersey include azaleas, buttercups, mountain laurels, rhododendrons, and Virginia cowslips.

The state's animals include deer, foxes, minks, muskrats, opossums, otters, rabbits, raccoons, and skunks. Wild ducks and geese are found along the marshy coast.
shores of the Atlantic Ocean. Game birds of the meadows and woodlands include partridges, pheasants, quail, ruffed grouse, and wild turkeys.

Clams, crabs, lobsters, menhaden, and oysters live in New Jersey's coastal waters. The state's bays and streams abound with bass, bluefish, crappies, pickerel, pike, salmon, shad, sturgeon, trout, and weakfish.

Climate. New Jersey has warm to hot summers and cold winters. Ocean breezes reduce summer temperatures and increase winter temperatures in a narrow strip along the eastern coast. Average July temperatures range from 76 °F (24 °C) in the southwest to 70 °F (21 °C) in the north. On July 10, 1936, Runyon had the state's highest temperature, 110 °F (43 °C). Average January temperatures range from 34 °F (1 °C) at Cape May to 26 °F (−3 °C) in the Appalachian Ridge and Valley Region. On Jan. 5, 1904, River Vale had the state's lowest temperature, −34 °F (−37 °C).

Snowfall averages about 13 inches (33 centimeters) a year in the south, and 50 inches (127 centimeters) in the north. New Jersey averages about 45 inches (114 centimeters) of precipitation (rain, melted snow, and other forms of moisture) a year. Precipitation is fairly evenly distributed throughout the state.

Economy

Despite its small size, New Jersey ranks among the leading industrial states. Most of the state's factories are in the Elizabeth-Jersey City-Newark area and in the Trenton-Camden area. Service industries have become the pillar of New Jersey's economy. Most of these industries are concentrated in the state's metropolitan areas.

The 127-mile (204-kilometer) long, beach-lined Atlantic seaboard is the center of New Jersey's tourist trade. Tourist activities in the state account for about $28 billion a year. New Jersey's proximity to New York City and Philadelphia helps the state's economy. These cities provide large markets for goods and services produced within New Jersey.

Natural resources of New Jersey include fertile soils and small deposits of minerals. Unlike many other states, New Jersey does not rely on its own resources for the raw materials of its industries.

Soil. Three types of soil are most common in New Jersey. In the north, the soil has a high limestone and glacial mineral content. Farmers in this region raise field crops and operate dairy farms. A rich subsoil of greensand marl lies under rich loam in central New Jersey. This mixture yields good vegetable crops. When mixed with fertilizer, the sandy soil of the south supports fruit orchards and vegetable farms.

Minerals. Stone—especially granite and traprock—is New Jersey's most abundant mined resource. Northern and central New Jersey produce almost all the stone in the state. Sand and gravel are found throughout New Jersey. Camden, Middlesex, Morris, and Ocean counties produce sand and gravel for construction. Cumberland County produces a large amount of industrial sand for glassmaking and foundry work. Other mined resources include clay, gemstones, greensand marl, peat, and zinc.

Service industries account for the largest part of New Jersey's gross state product—the total value of all goods and services produced in a state in a year.

New Jersey's leading service industries are (1) community, business, and personal services and (2) finance, insurance, and real estate. Each of these groups contributes an equal share to the gross state product.

Community, business, and personal services include such businesses as private health care, hotels and casinos, and private research laboratories. Atlantic City has many hotels and casinos. Business services include computer programming, management consulting, and temporary help. One of the world's most famous private research complexes, Bell Laboratories, is near New Jersey.

*GSP = gross state product, the total value of goods and services produced in a year.

Less than one-half of 1 percent.

Figures are for 1988.

Cookies are inspected at a factory in Fair Lawn. Food processing ranks as New Jersey's third most important manufacturing activity. New Jersey is a leading food-processing state.

Providence. Now part of Lucent Technologies Inc., Bell Laboratories was formerly operated by AT&T Corp.

Northern New Jersey is one of the nation's leading centers of commercial real estate, which includes office buildings and factories. The largest U.S. life insurance company, Prudential, is headquartered in Newark.

Wholesale and retail trade ranks next among New Jersey's service industries. Northern New Jersey is one of the country's leading centers for the wholesale trade of chemicals and machinery. The Newark-Elizabethtown port is a major U.S. port for international trade. The Newark and Bergen-Passaic areas lead in retail trade, which includes discount stores and service stations.

Other service industries include (1) government and (2) transportation, communication, and utilities. Government services include military activities and the operation of public schools and hospitals. Many people are employed by New Jersey's public school system. Two major United States utility companies, Public Service Enterprise Group and GPU Energy, are based in New Jersey. Information about transportation and communication in the state appears later in this section.

Manufacturing. Goods manufactured in New Jersey have a value added by manufacture of about $48 billion a year. Value added by manufacture represents the increase in value of raw materials after they become finished products. New Jersey ranks among the leading states in manufacturing and processing. Many foreign manufacturers operate factories in New Jersey.

New Jersey is one of the leading states in chemical production, and chemicals rank as New Jersey's leading manufactured product. Pharmaceuticals are the most valuable types of chemicals made in the state. Several major pharmaceutical companies—American Home Products, Aventis Pharma, Johnson & Johnson, Merck, Pharmacia, and Schering-Plough—have their world headquarters in New Jersey. Shampoo, lotion, perfume, and other personal care products also make up an important part of New Jersey's chemical industry. Other chemical products made in New Jersey include detergents, industrial chemicals, paint, and plastics resins.

Computer and electronic products rank second in terms of value added by manufacture. The state's electronic manufactures include wireless and broadcast communications equipment, electronic components, and surveillance and navigation equipment.

Food products rank third among New Jersey's manufactured products. Factories in northeastern New Jersey process a wide variety of foods, including bakery products, beverages, fruits, meats, roasted coffee, sugar and confectionery products, and vegetables. Food-processing plants in southwestern New Jersey process and can fruits and vegetables brought in from nearby truck gardens and orchards.

Other products manufactured in New Jersey include fabricated metal products, plastics and rubber products, printed materials, and machinery. Fabricated metal products made in New Jersey include metal cans, pipe fittings, and nails and screws. The state's plastics products include bags, sheets, and bottles. The major types

A chemical plant in Bayonne is one of about 1,000 such facilities in New Jersey. The production of chemicals is the state's leading manufacturing activity.
of printed materials produced in New Jersey are business forms, books, and newspapers. Types of machinery made in New Jersey include metalworking machinery, papermaking machinery, and refrigeration equipment.

**Agriculture**. Farmland covers nearly 20 percent of New Jersey's land area. The state has about 9,600 farms. Greenhouse and nursery products are New Jersey's most valuable source of agricultural income. These products are raised chiefly in the northeastern part of New Jersey for sale in the New York City area. Millions of roses are grown in the state yearly. New Jersey greenhouses also raise chrysanthemums, geraniums, lilies, orchids, and poinsettias. The state's leading nursery products include grass sod and such ornamental shrubs as arborvitae, holly, and juniper.

Milk is the second most valuable source of farm income in New Jersey. Dairy farms flourish in the northwestern part of the state, especially in Hunterdon, Sussex, and Warren counties. Burlington and Salem counties in southern New Jersey also rank high in milk production.

New Jersey is also an important vegetable-growing state. The state is one of the nation's leading producers of asparagus, bell peppers, eggplant, endive, lettuce, and spinach. New Jersey farmers also raise cabbage, snap beans, and sweet corn. The largest vegetable farms are in the southern half of the state.

Blueberries and cranberries are the most valuable fruit crops grown in the state. New Jersey ranks among the leading states in the production of these fruits. The state also ranks high in the production of apples, peaches, and strawberries. Most of New Jersey's fruit orchards are in the southern third of the state. Warren County, in northwestern New Jersey, is a major producer of apples.

Soybeans, corn, and wheat are New Jersey's chief field crops. Soybeans and wheat are grown primarily in the southernmost counties. Corn is grown mainly in New Jersey's northwestern and southwestern counties.

**Mining**. The most important products mined in New Jersey are crushed stone, and sand and gravel. The most valuable types of crushed stone quarried in the state are traprock and granite. Most of the traprock comes from Somerset and Mercer counties. Granite comes from Morris and Sussex counties. Sand and gravel are mined mainly in coastal areas. The state's other mined products include clays, greensand marl, and peat.

**Fishing industry**. New Jersey's commercial fish catch has an annual value of about $100 million. The state is a leader in the value of clams caught. Huge clam beds extend from Barnegat Bay to Cape May. The fish catch also includes blue crab, flounder, lobster, mackerel, menhaden, pogies, scallops, squid, swordfish, and whiting.

**Electric power**. Nuclear power plants provide about 75 percent of New Jersey's electric power. Coal-burning plants provide about 15 percent of the state's electric power. Plants that burn natural gas supply most of the remaining power. Petroleum-burning plants produce a small amount of the state's electric power.

**Transportation**. New Jersey lies between New York City and the western and southern states. This location makes its highways and railroads important links in the nation's transportation system. New Jersey is a leader in containerization (transporting goods by containers along a network of airplanes, ships, trains, and trucks).

Passenger trains connect many New Jersey cities with New York City and Philadelphia. These trains include swift commuter lines that carry thousands of New Jerseyites to jobs in these two large cities. Several railroad lines provide freight service in New Jersey.

**Economy of New Jersey**

This map shows the economic uses of land in New Jersey and where the state's leading farm and mineral products are produced. Major manufacturing centers are shown in red.

![Economy of New Jersey map](image)

**Farmworkers plant lettuce** on a New Jersey truck farm. Such farms supply vegetables for people in nearby cities. New Jersey is an important vegetable-growing state.
In 1891, New Jersey became the first state to help local communities build roads. New Jersey now has about 35,000 miles (56,000 kilometers) of roads and highways. The New Jersey Turnpike is 122 miles (196 kilometers) long. It runs from Deepwater in the southwest part of the state to Ridgefield Park in the northeast. The turnpike was opened in 1952 and was extended in 1956. It is 12 lanes wide in some areas, making it one of the widest highways in the United States. More than 200 million vehicles travel the turnpike each year. The 173-mile (278-kilometer) Garden State Parkway crosses New Jersey between the New York state line near Montvale and Cape May, at New Jersey's southern tip. The Garden State Parkway was completed in 1957.

Bridges and tunnels link New Jersey and neighboring states. The George Washington Bridge, which is one of the world's longest suspension bridges, spans the Hudson River between Fort Lee and New York City. The Bayonne Bridge, which is one of the longest steel arch bridges in the world, crosses Kill Van Kull, a channel between Bayonne and Staten Island. Bridges across the Delaware River include the Benjamin Franklin Bridge between Camden and Philadelphia and the Delaware Memorial Bridge Twin Span between Deepwater and the New Castle, Delaware, area. The Holland and Lincoln auto tunnels and the PATH tubes—four rapid transit tunnels—link New Jersey and New York City. All of these tunnels run beneath the Hudson River.

Newark International Airport is one of the country's busiest airports. It serves many passengers going to or from New York City as well as those headed to or from northeastern New Jersey. The first regular air passenger service in the United States began operating in 1919 between Atlantic City and New York City.

New Jersey has a number of important ports along the Hudson and Delaware rivers, in Newark and Raritan Bay, and along Kill Van Kull and Arthur Kill. New Jersey's part of the Atlantic Intracoastal Waterway extends for 117 miles (188 kilometers) from Manasquan Inlet to Cape May. This waterway is protected from the ocean by barrier beaches, and thus offers safe passage for small boats.

Communication. About 245 newspapers, including about 20 dailies, are published in New Jersey. The leading papers include the Courier-Post of Cherry Hill, the Star-Ledger of Atlantic City, The Record of Hackensack, and The Times of Trenton. New York City and Philadelphia newspapers have wide circulation in New Jersey. The state's first weekly newspaper, the New Jersey Gazette, began publishing in Burlington in 1777. New Jersey's first daily newspaper, the Newark Daily Advertiser, was founded in 1832. Nearly 450 periodicals are published in the state.

New Jersey has about 85 radio stations and 10 television stations. Cable TV systems and Internet providers also serve communities statewide. Many pioneer efforts in radio broadcasting took place in New Jersey. Joseph Henry transmitted the first radio impulse at Princeton in 1840. WJZ, the second licensed commercial broadcasting station in the country, was established in Newark in 1921. This station now operates in New York City under the call letters WPLJ The first New Jersey television station, WATV, began operating in Newark in 1948. It is now WNET of New York City. Today, only UHF (ultrahigh frequency) commercial stations broadcast in New Jersey. The state created the New Jersey Public Broadcasting Authority in 1969. The authority operates a four-station UHF statewide public television system. New York and Pennsylvania stations also serve New Jersey.

New Jersey boasts many other "firsts" in communication. The first interstate long-distance telephone call was made from New Brunswick, New Jersey, to New York City in 1877. The first coast-to-coast direct dialing system was established in Englewood in 1951. Telstar 1, the first communications satellite to transmit live television across the Atlantic, was designed at New Jersey's Bell Laboratories. The satellite was launched in 1962.

**Government**

**Constitution** of New Jersey was adopted in 1847. New Jersey had two earlier constitutions, adopted in 1776 and 1844. Either house of the state Legislature may propose constitutional amendments. Amendments must be approved by three-fifths of the members of both houses, or by a majority vote of both houses in two successive years. To become law, amendments must also be approved by a majority of the voters in a general election. The Constitution does not provide for a constitutional convention that can amend the Constitution.

**Executive.** The governor is the only New Jersey executive official elected by the people. The governor may serve any number of terms, but not more than two in succession.

The governor is responsible for appointing most of the high-level executive officials of New Jersey's government. These officials include the attorney general; secretary of state; state treasurer; and the commissioners of banking and insurance, personnel, community affairs, education, environmental protection, health and senior
services, and labor. The state Board of Agriculture appoints the secretary of agriculture. Board members are recommended by an agricultural convention and appointed by the governor. All the governor's appointments must be approved by the state Senate. Most executive officials serve four-year terms.

**Legislature** of New Jersey consists of a 40-member Senate and an 80-member General Assembly. Voters in each of the state's 40 legislative districts elect one senator and two members of the Assembly. Senate terms are on 10-year cycles of two, four, and four years. Senators are elected to a two-year term in the election after each U.S. population census. The next two terms are each for four years. Members of the Assembly are elected to two-year terms. The New Jersey legislature meets annually, beginning on the second Tuesday of January. Legislative sessions have no time limit.

**Courts.** New Jersey's highest court, the state Supreme Court, hears cases involving constitutional problems, capital punishment, and other major matters. The Supreme Court has a chief justice and six associate justices. The state Supreme Court is New Jersey's chief trial court. It has three divisions—Appellate, Law, and Chancery. The Superior Court has 362 judges. The governor, with the Senate's approval, appoints both the members of the Supreme and Superior courts to seven-year terms. If the governor reappoints them once, the judges may serve until they are 70 years old.

Lower courts include municipal courts, surrogate courts, and tax courts. The governor of New Jersey, with the Senate's approval, appoints all lower court judges except those of the single-municipal courts. Judges of single-municipal courts are appointed by local governments. New Jersey voters elect surrogate judges.

**Local government.** New Jersey is the only state in which county governments are called boards of chosen freeholders. This name comes from colonial days, when only freeholders (property owners) could hold public office. All 21 New Jersey counties have boards of from three to nine members. All freeholders in New Jersey's 21 counties are elected to three-year terms.

New Jersey's 566 municipalities include cities, towns, townships, boroughs, and villages. Most have the mayor-council, commission, or council-manager form of government. Most of the large cities have the mayor-council form. Municipalities get their charters from the state. They choose from among a variety of charters. Before a municipality can adopt a new charter or revise an existing one, it must create a charter study commission. Local voters must approve the new or revised charter.

**Revenue.** Taxes account for more than half of the state's general revenue income. Most of the rest comes from federal grants, charges for government services, rents on leased property, casino taxes, and a state

*Democratic-Republican*
lottery. The chief sources of tax revenue are a personal income tax and a general sales tax. Other major sources are taxes on public utilities, corporate income, motor fuels, motor vehicle licenses, tobacco products, insurance premiums, and taxes on inheritance.

Politics. In the late 1800's, most New Jersey governors were Democrats. Since 1900, the office has been about equally divided between Democrats and Republicans. The Republicans had a majority in the state Senate and General Assembly during most of the early 1900's. But Democrats won increased support in state elections during the late 1950's and early 1960's. Since then, control of the houses of the legislature has passed between the Democrats and the Republicans several times.

Since 1856, New Jersey's electoral votes have been evenly split between Republican and Democratic presidential candidates. For New Jersey's electoral votes and voting record, see Electoral College (table).

**History**

**Indian days.** Before European settlement, perhaps 8,000 Indians lived in what is now New Jersey. They spoke an Algonquian dialect and called themselves Lenape, meaning genuine people. Europeans called them the Delaware. The Indians lived by hunting, fishing, gathering, and by planting corn, squash, and beans. See Delaware Indians.

**Exploration.** Giovanni da Verrazzano, an Italian navigator in the service of France, was probably the first European to explore the New Jersey coast. He reached the coast in 1524. Henry Hudson, an English sea captain employed by the Netherlands, explored the Sandy Hook Bay area in 1609. He also sailed up the river that now bears his name. The Dutch explorer Cornelius Mey sailed the Delaware River in 1614. Cape May was later named for him. Many Dutch trading ships visited the New Jersey area during the 1600's.

**Settlement.** The Dutch and the Swedes were the first white settlers in New Jersey. The Dutch founded an outpost in Pavonia (now part of Jersey City) about 1630. Indian uprisings prevented permanent settlement until 1660. That year, the Dutch built the fortified town of Bergen (now part of Jersey City). Bergen was New Jersey's first permanent white settlement.

Traders and settlers from Sweden arrived in southern New Jersey in 1638. The Dutch settlers feared Swedish competition in the fur trade. The Dutch forced the Swedes out of the New Jersey area in 1635.

**English control.** English armies won control of New Jersey and other Dutch North American possessions in 1664. King Charles II of England gave the New Jersey area to his brother, James, Duke of York. James, in turn, gave it to two of his friends, Lord John Berkeley and Sir George Carteret. James named the area New Jersey in honor of Carteret, who had served as governor of Jersey, an island in the English Channel. Berkeley and Carteret offered to sell the land to colonists at low prices. They also allowed settlers to have political and religious freedom. These policies attracted many settlers to New Jersey.

In 1674, a group of Quakers headed by Edward Blyllynge bought Berkeley's share of New Jersey. Two years later, the colony was divided into two sections—West Jersey and East Jersey. Blyllynge and his associates made West Jersey the first Quaker colony in America. Carteret owned East Jersey until his death in 1680. Another group of Quakers, called the Twenty-Four Proprietors, bought East Jersey in 1682.

New Jersey's political and religious freedom attracted a variety of groups. Puritans, Baptists, and Scotch-Irish arrived during the late 1600's. White settlers imported slaves from Africa. However, the large number of landowners and groups of settlers led to disputes over who owned the land. The colonists also objected to paying rent to the owners. Many colonists rioted during the 1690's. The owners gave up East and West Jersey in 1702. England then united the two colonies as a single royal colony.

**Colonial days.** New Jersey had twin capitals from 1703 to 1775. They were Perth Amboy, the former capital of East Jersey, and Burlington, the former capital of West Jersey. At first, the governor of New York also ruled New Jersey. But strong protests from the colonists forced England to give New Jersey its own governor in 1738. Lewis Morris, the first colonial governor, served from 1738 to 1746.

Colonial New Jersey was a rural society. By the 1760's, the colony had about 100,000 people. The English king appointed the colonial governor and a 12-member council. The people elected a colonial assembly. But only freeholders who owned property valued at 50 pounds or more were allowed to vote. Fifty pounds in 1760 equals about $2,000 today.

**The Revolutionary War.** During the 1760's, Britain passed a series of laws that caused unrest in New Jersey and the other American Colonies. Most of these laws either set up severe taxes or restricted colonial trade. Some New Jerseyites urged the colonists to remain loyal to Britain in spite of the laws. But many colonists believed that political and religious freedom could be retained only through independence from Britain.

In 1774, a group of New Jerseyites dressed as Indians burned a supply of British tea stored in a ship at Greenwich, near Salem. This event, called the Greenwich Tea Burning, was similar to the more famous Boston Tea Party of 1773. Like the Boston Tea Party, the action symbolized colonial opposition to British taxation policies. See Boston Tea Party.

The Revolutionary War began in Massachusetts in 1775. Large numbers of New Jerseyites joined the patriots in their fight for independence, and many other New Jerseyites fought on the British side. New Jersey's location between New York City and Philadelphia made it a major battleground during the war. The Americans and British fought nearly a hundred engagements in New Jersey. The most important ones included the battles of Trenton in 1776, Princeton in 1777, and Monmouth in 1778.

Before the Battle of Trenton, George Washington made his famous surprise crossing of the Delaware River on Christmas night. During the war, Washington's army camped two winters at Morristown and a third at
Bound Brook. See Revolutionary War in America (The war in the North).

During the Revolutionary period, two New Jersey cities served as the temporary national capital. They were Princeton, from June 30 to Nov. 4, 1783, and Trenton, from Nov. 1 to Dec. 24, 1784.

New Jersey declared its independence from Britain and adopted its first constitution on July 2, 1776. On Nov. 26, 1778, it ratified the Articles of Confederation (the forerunner of the United States Constitution).

The New Jersey delegates to the Constitutional Convention of 1787 proposed a plan to protect the interests of small states. This New Jersey Plan suggested that all states have equal representation in Congress. But the convention adopted the Great Compromise instead. The compromise created the present two-house Congress. The states have equal representation in the Senate. Their representation in the House of Representatives is based on population. New Jersey became a state on Dec. 18, 1787, when it ratified the U.S. Constitution. It was the third state to do so. William Livingston became New Jersey’s first state governor.

The 1800’s. One of the most famous duels of all time was fought at Weehawken in 1804. Aaron Burr, the Vice President of the United States, shot and killed his political rival, Alexander Hamilton. In 1804, New Jersey passed legislation to begin the gradual freeing of slaves held in the state. The act freed all children born into slavery when the men reached the age of 25 and the women reached 21.

Public demand for a more democratic state government led to the adoption of a new state constitution in 1844. The new Constitution provided for the separation of powers among the legislative, judicial, and executive branches of the state government. The Constitution also provided for a bill of rights and for the election of the governor by the people. In 1845, Charles C. Stratton became the first New Jersey governor so elected.

About 88,000 New Jersey men served in the Union army during the American Civil War (1861-1865). But there was much pro-Southern sympathy in the state. In 1864, New Jersey was one of only three states that voted against the reelection of President Abraham Lincoln.

New Jersey was one of the first great industrial states. As early as 1792, Paterson had become a textile center. Later, the city became known for the manufacture of locomotives and for silk production. Other New Jersey cities grew because of industry. Trenton specialized in clay products, iron, and steel. John Roebling, who built the Brooklyn Bridge, had his firm in Trenton. Camden, Elizabeth, Jersey City, Newark, and Passaic all became major manufacturing centers in the 1800’s.

Improvements in transportation during the first half of the 1800s helped New Jersey to grow industrially. New canals connected New Jersey cities to Philadelphia and New York City. New railroads expanded the transportation system. As industry grew, thousands of Europeans came to New Jersey cities to work in factories. At first, most came from Ireland and Germany. Later, large numbers came from Italy and eastern Europe. By 1910, more than half the state’s people had been born outside the United States or had parents who were born in other countries. With the growth of industry, city populations increased and farm populations decreased. By 1900,
Henry Hudson, an English sea captain in the service of the Netherlands, explored Sandy Hook Bay in 1609. He also sailed up the river that now bears his name.

Bergen, New Jersey's first permanent European settlement, was built by the Dutch in 1660. It is now part of Jersey City.

Casino gambling began in Atlantic City in 1978.

Washington crossed the Delaware at the head of the Colonial army on Christmas night, 1776. The next day, his forces defeated a Hessian army at Trenton.

Molly Pitcher took the place of her fallen husband on a cannon crew during the Battle of Monmouth in 1778.

Important dates in New Jersey

1524 Giovanni da Verrazzano explored the New Jersey coast.
1609 Henry Hudson explored Sandy Hook Bay and sailed up the Hudson River.
1630 The Dutch established an outpost in Pavonia.
1660 The Dutch established a permanent settlement in Bergen (now part of Jersey City).
1664 The Dutch surrendered New Jersey to England.
1776 New Jersey adopted its first constitution.
1783-1784 Princeton and Trenton each served briefly as the national capital.
1787 New Jersey became the third state when it ratified the U.S. Constitution on December 18.
1844 New Jersey adopted its second constitution.
1858 The first dinosaur skeleton discovered in North America was found buried in Haddonfield.
1869 Rutgers defeated the College of New Jersey (now Princeton), by a score of 6 to 4, in New Brunswick in the world's first intercollegiate football game.
1879 Thomas A. Edison developed the first practical incandescent lamp in Menlo Park.
1911 Many reforms were enacted under Governor Woodrow Wilson.
1947 New Jersey adopted its third constitution.
1952 The New Jersey Turnpike opened.
1969 New Jersey voters approved a state lottery to raise money for the state government and for the schools.
1976 New Jersey adopted an individual income tax.
1978 Casino gambling began in Atlantic City.
1993 Christine Todd Whitman became the first woman to be elected governor of New Jersey.
There, annual tensions, the Great Depression began. Hoboken's entertainment area became the world's busiest highways. The turnpike links the Philadelphia and New York City metropolitan areas. The Garden State Parkway, completed in 1955, runs along the New Jersey coast.

Between 1976, the state adopted a sales tax and several bond issues to help pay for major government programs. One bond issue supplied money for new state colleges, highways, institutions, and commuter train facilities. Another paid for water conservation projects and for a program to fight water pollution. In 1969, voters approved a state lottery to raise money for the state government and for the schools.

The late 1900's. The state continued to seek new sources of revenue. In 1976, the Legislature adopted an individual income tax for the first time. Also in 1976, the voters passed a referendum permitting gambling casinos in Atlantic City to help raise more money for the disabled and the elderly. The first casino opened in 1978.

Large urban renewal projects of the late 1900's upgraded parts of several New Jersey cities. The program in Trenton included construction of a group of state government office buildings and a cultural center. In Newark, the state built or expanded several college and university facilities, including a new branch campus for Rutgers The State University of New Jersey.

Although passenger railroad travel has declined nationwide since the mid-1900's, New Jersey kept its position as a major rail center. Newark Airport began a major construction program in 1963 to expand passenger and cargo service. In the 1980's, it became one of the world's busiest airports.

New Jersey, the most densely populated state, faces problems related to overcrowding. Its population density strains the environment and puts huge demands on the state government to provide social services.

Recent developments. In 1994, Christine Todd Whitman became the state's first female governor. She left office in 2001 when President George W. Bush named her to head the U.S. Environmental Protection Agency.

Paul G. E. Clemens and Robert M. Hornblon

Early motion pictures were made in studios at Fort Lee. Silent film star Mary Pickford, shown with director Maurice Tourneur, left, made Poor Little Rich Girl at Fort Lee in 1917.

cratic principles but failing to end such injustices as poverty, racial discrimination, and class distinctions. Many New Leftists opposed capitalism and believed the desire for profits leads to imperialism, a policy that favors extending influence over another country.

People who identified themselves with the New Left were not all members of a single organization, and they frequently disagreed among themselves. Members of the New Left ranged from pacifists to violent revolutionaries. Many New Leftists favored such tactics as nonviolent civil disobedience. But their actions often led to bloody clashes with the police and other law-enforcement officials. The most important elements of the New Left included the militant wings of the peace movement during the Vietnam War, the movement for racial equality, and the students’ rights movement.

The peace and civil rights movements appealed especially to young people. Their experiences in civil rights and peace demonstrations convinced many of them that war and discrimination could be ended only by a general reformation of American society. Several radical student organizations appeared in the early 1960’s, including the Students for a Democratic Society (SDS) and the Free Speech Movement. Radical students began to consider the university as an accomplice of war and racism. They used disruptive tactics in an effort to reform their universities or to use them as a base for revolutionary activities.

Most members of the New Left showed little interest in conventional politics and did little to get sympathetic candidates elected to public office. But many people believe that the antiwar movement helped persuade President Lyndon B. Johnson not to run for reelection in 1968. After 1968, the New Left split into several factions. For example, the revolutionaries split over tactics for defeating imperialism. Some urged an alliance with American workers, but others favored organizing the world’s poor and nonwhite peoples.

The New Left failed to bring about radical changes in American society. But it formed the basis for several movements that remain active today, such as the women’s and environmentalist movements.

See also Radicalism (in the United States); Black Panther Party; Students for a Democratic Society; Riot (During the 1900’s).

New London, Connecticut (pop. 25,671), is the home of the United States Coast Guard Academy. It is also the trading, banking, transportation, and distribution center for southeastern Connecticut. The city’s position at the mouth of the Thames River, near the eastern entrance of Long Island Sound, makes it an important seaport (see Connecticut [political map]). New London and Norwich form a metropolitan area with 293,566 people. During the mid-1800’s, New London’s whaling fleet was second in size only to that of New Bedford, Massachusetts. Today, copper, paper products, and steel coils are the principal cargoes shipped to New London’s State Pier.

New London is the center of research and development for a pharmaceutical manufacturer. The U.S. Naval Submarine Base and a submarine manufacturer are located across the Thames River in Groton. Their presence has attracted a number of defense-related consulting and engineering firms to New London. The city is the home of Connecticut College and Mitchell College.

New London was settled in 1646 and incorporated in 1784. In 1781, during the Revolutionary War in America, the city was burned by a British raiding party led by the American traitor Benedict Arnold. New London has a council-manager form of government.

Stephen Fagin

New London Naval Submarine Base, in Groton, Connecticut, is the chief training center of the United States Navy’s submarine force. It also houses the Submarine School and headquarters of the Submarine Group Two. The base covers 497 acres (201 hectares) on the Thames River, 1 mile (1.6 kilometers) northeast of New London. Connecticut gave the land to the federal government in 1868 for naval purposes. The U.S. Navy established a coaling station there in 1872. The Navy first used submarines at the New London naval base in 1900. The submarine base houses the offices of over 40 separate military commands. It also is the home of the U.S.S. Nautilus Memorial and the Submarine Force Library and Museum. The Nautilus, the world’s first nuclear-powered submarine, was built in Groton and launched in 1954.

Critically reviewed by the United States Navy

New mathematics was an educational movement during the late 1950’s and the 1960’s that attempted to change the teaching of mathematics in the United States. The growth of space exploration, computer technology, and other scientific fields had created a need for better training in mathematics. To meet this need, several independent groups of mathematicians and educators in the United States tried to design better math curriculums. Their goals were to modernize course content, give students a deeper understanding of mathematical principles, and encourage creative problem solving.

Traditional math programs stressed the development of basic computational skills—such as how to add, subtract, multiply, and divide—through repetitious drills and memorization. New math programs urged students to understand concepts rather than learn rules. To provide a better understanding of numbers, for example, many programs taught students to work problems in numeration systems with bases other than 10 (see Numeration systems).

The educators who developed the new programs agreed on general goals but disagreed on specific goals and methods. As a result, many different curriculums were created. All became known as the new mathematics or new math.

Because of several obstacles, however, few schools established effective new math programs. For example, many institutions did not give teachers an adequate opportunity to learn the new material. Textbooks continued to present old methods and goals. Sections on new math topics—such as bases other than 10 and sets (collections of objects or ideas)—were merely added to the old lessons. (See Set theory.)

New math topics were often taught with the old focus on computational skills rather than on the learning of concepts. For example, teachers asked students to translate numbers from base 10 to another base rather than work math problems entirely within the non-10 base. During the 1970’s, students’ achievement scores declined, and many people blamed new math. New math fell out of favor and was replaced by an even stronger focus on basic skills. Thus, new math was never widely implemented.

Karen Connors Fuson
Scattered pines grow in a canyon near Los Alamos. Thousands of people visit New Mexico each year to enjoy its warm climate, beautiful scenery, and rich Spanish and Indian cultures.

New Mexico  The Land of Enchantment

New Mexico, a Southwestern state of the United States, is called the Land of Enchantment because of its scenic beauty and rich history. Every year, thousands of tourists go to this state for hunting, fishing, skiing, or sightseeing. New Mexico is the fifth largest state in area. Only Alaska, Texas, California, and Montana have a greater area. But the state is thinly populated. Mountain ranges, rugged canyons, and rocky deserts cover much of New Mexico.

A person vacationing in New Mexico might see the state as a land of beautiful scenery, Spanish fiestas, and Indian ceremonies. But a scientist would think of New Mexico as a center of research into rockets and nuclear energy. An oil company executive might regard the state as a rich source of gasoline for automobiles, or of natural gas for cooking and heating. A retired couple might choose to make their home in the southern part of New Mexico because its location and high altitude provide warm, sunny days and cool nights. A rancher might be impressed by New Mexico's vast stretches of grazing land.

Much of New Mexico's growing industry springs from the science of the nuclear age. The first atomic bomb was built and exploded in New Mexico in 1945. Today, scientists in New Mexico search for a way to make space rockets travel on nuclear power. Other scientists develop ways to use nuclear power for generating electricity, or work on improving nuclear weapons for defense.

New Mexico ranks among the leading states in mining. Natural gas and petroleum are New Mexico's most important mineral products by far. Large deposits of gas and petroleum lie in both the northwestern and southeastern parts of the state. In addition, New Mexico's resources include major deposits of coal, copper, potash, and uranium.

Cattle ranching is the most important type of farming in the state. Thousands of cattle graze on the vast plains.

The contributor of this article is Stanley A. Morain, Director of the Earth Data Analysis Center at the University of New Mexico.
Interesting facts about New Mexico

**El Camino Real** (the Royal Highway) stretched from Santa Fe to Mexico City. It was the first road established by Europeans in what is now the United States. It was traveled about 1580 and was later used primarily as a trade route. Portions of it still exist and can be explored.

**The Smokey Bear Historical State Park** was established in Capitan in 1979. The symbol of Smokey was first used by the United States Forest Service in 1944. In 1950, a real "Smokey Bear" was found clinging to a burned tree after a fire swept through Lincoln National Forest. The orphaned bear cub became the living Smokey Bear. The bear died in 1976 and was buried in what is now Smokey Bear Historical State Park.

**The Palace of the Governors** in Santa Fe is the oldest government building in the United States. The Spanish built it as part of a fortress during the winter of 1609-1610. In 1909, it was converted to the Palace of the Governors History Museum. The building now houses exhibits on Spanish, Mexican, and American colonization dating back to the late 1500's.

**Taos Pueblo** is a Pueblo Indian village in north-central New Mexico. The Pueblo Indians have traditionally lived in stone or adobe structures that resemble modern apartment buildings.

and in the mountain valleys of New Mexico.

New Mexico’s colorful past gives the state important tourist attractions. Still standing are the ruins of an apartment house with about 800 rooms built by the Indians hundreds of years before Christopher Columbus arrived in America. Spain ruled the land for more than 220 years. The Spanish influence may be seen today in the names of places, in the churches of early missionaries, in foods, and in customs and holidays. Colorful people such as Kit Carson, Geronimo, and Billy the Kid played major parts in the history of the New Mexico area in territorial days.

Many other historical features capture the interest of visitors to New Mexico. Within the state remain portions of the oldest road established by Europeans in the United States. This route, called El Camino Real (the Royal Highway), was first traveled about 1581. Santa Fe, the capital of New Mexico, ranks as the oldest seat of government in the United States. It was founded as the capital of a Spanish province as early as 1609 or 1610. The largest city in New Mexico is Albuquerque, which the Spaniards founded in 1706.
New Mexico in brief

Symbols of New Mexico
On the state flag, adopted in 1925, the ancient sun symbol of the Zia Pueblo Indians appears in crimson on a gold field. These were the colors of Queen Isabella of Castile that the Spanish Conquistadors brought to the New World. On the state seal, commissioned in 1912, a large eagle shielding a smaller eagle represents the annexation of New Mexico by the United States.

Land and climate
Area: 121,599 sq. mi. (314,939 km²), including 234 sq. mi. (605 km²) of inland water.
Elevation: Highest—Wheezer Peak, 13,161 ft. (4,011 m) above sea level. Lowest—2,817 ft. (859 m) above sea level at Red Bluff Reservoir in Eddy County.
Record high temperature: 122 °F (50 °C) at Waste Isolation Pilot Plant near Carlsbad on June 27, 1994.
Record low temperature: −50°F (−46 °C) at Gavilan, near Lindrith, on Feb. 1, 1951.
Average July temperature: 74 °F (23 °C).
Average January temperature: 34 °F (1 °C).
Average yearly precipitation: 13 in. (33 cm).

Important dates
1540-1542 Francisco Vázquez de Coronado of Spain explored the New Mexico region.
1598 Juan de Oñate founded New Mexico’s first permanent Spanish settlement at San Juan.
1821 New Mexico became a province of Mexico.
1848 Mexico ceded New Mexico to the United States.
1848-1849 William Becknell opened the Santa Fe Trail.

Population. The 2000 United States census reported that New Mexico had 1,819,046 people. This includes over 750,000 Hispanic Americans and nearly 175,000 American Indians. The population has increased 21 percent over the 1990 figure, 1,515,069. According to the 2000 census, New Mexico ranks 36th in population among the 50 states. More than half of New Mexico's people live in the state's three metropolitan areas. These areas are Albuquerque, Las Cruces, and Santa Fe.

Most New Mexicans are descended from one of the three major groups that settled the area—Indians, Spaniards, and English-speaking Americans. New Mexico has a higher percentage of Indians and Hispanics than any other state. About 42 percent of the people are Hispanic, and nearly 10 percent are Indian. The way of life of the Indians may be much like that of their ancestors. The Indians might live in a pueblo (village) or on a reservation. The Spanish influence shows in place names, foods, and customs. Many New Mexicans speak both English and Spanish. Non-Hispanic whites, the state's largest group, account for about 45 percent of the population. New Mexico has small numbers of African Americans and Asians.

Schools. In the early 1600's, Spanish Roman Catholic priests began establishing schools in New Mexico to teach Christianity to the Indians. Public education was established in the state in the late 1800's.

The State Board of Education, which consists of 10 elected members and 5 members appointed by the governor, establishes school policies. The board hires a superintendent of public instruction, who carries out the policies. State law requires children from ages 5 through 17 to attend school. For the number of students and teachers in New Mexico, see Education (table).

Libraries and museums. The New Mexico Territorial Library was established in Santa Fe in 1851. Part of this collection was used to form the State Library. The state's first public library was founded in Cimarron in 1871.

The Museum of New Mexico in Santa Fe includes the Fine Arts Museum, Museum of Indian Arts and Culture, Museum of International Folk Art, and Palace of the Governors. The Wheelwright Museum of the American Indian, also in Santa Fe, features Navajo ceremonial art. The New Mexico Museum of Natural History and Science in Albuquerque has exhibits on the Southwest. The Los Alamos Bradbury Science Museum traces the development of nuclear energy. The Albuquerque Museum has cultural arts relating to the region. Other museums include the Farm and Ranch Heritage Museum in Las Cruces, the National Atomic Museum in Albuquerque, and the Roswell Museum and Art Center in Roswell.

Universities and colleges

This table lists the universities and colleges in New Mexico that grant bachelor's or advanced degrees and are accredited by the North Central Association of Colleges and Schools.

The University of New Mexico, located in Albuquerque, is the state's largest university or college. The Humanities Building, shown here, stands on the university's central campus.
New Mexico's scenery and outdoor activities attract visitors throughout the year. The state offers skiing in winter, fishing in spring and summer, and hunting in the fall. Scenic beauty ranges from rose-colored deserts to snow-capped mountains. Lovers of history can visit Indian ruins, frontier forts, and Spanish missions.

Indian ceremonies, Spanish fiestas, and local rodeos are among the most interesting events for visitors. The dates of events may vary from year to year, and among the different tribes and pueblos. Numerous Indian ceremonies are held throughout the year.

**Places to visit**

Following are brief descriptions of some of New Mexico's most interesting places to visit.

**Carlsbad Caverns National Park.** This series of huge caves in southeastern New Mexico is one of the world's great natural wonders. Lighted trails offer an excellent opportunity for visitors to see fantastic rock formations. Hundreds of thousands of bats fly out of the caverns at dusk and return at dawn. See Carlsbad Caverns National Park.

**Chaco Culture National Historical Park,** located near Farmington, is the site of ruins of early Indian culture. See Chaco Culture National Historical Park.

**Gila Wilderness,** near Silver City, became—in 1924—the first area in the country to be set aside as a national wilderness. It is preserved in its natural condition.

**Los Alamos Bradbury Science Museum** shows the development of nuclear energy.

**Pecos National Historical Park,** near Santa Fe, contains the ruins of what was once the largest Indian pueblo in New Mexico. See Pecos National Historical Park.

**Puye Cliff Dwellings** are ancient Indian "apartment houses" west of Española.

**Salmon Ruins,** near Bloomfield, is a site of archaeological importance. It features pueblo ruins and a nearby museum.

**San Miguel Mission,** in Santa Fe, was built by the Spaniards in about 1610 and was restored in 1710.

**National forests, monuments, and wilderness areas.** New Mexico has seven national forests. Gila, north of Silver City, is the largest. The others are Apache, near Luna and Reserve; Carson, near Taos; Chavela, which consists of several separate forests; Coronado, near Rodeo; Lincoln, near Alamogordo; and Santa Fe, near Santa Fe. Apache and Coronado national forests lie partly in Arizona. Several areas of the forests are preserved as national wilderness areas.

There are 10 national monuments in New Mexico. They include outstanding remains of ancient Indian civilization. They are Aztec Ruins, an ancient pueblo; Bandelier, the ruins of four pueblos; Capulin Volcano, the cone of an extinct volcano; El Malpais, prehistoric lava flows near Grants; El Morro, the site of Inscription Rock; Fort Union, an old Santa Fe Trail military post; the Gila Cliff Dwellings, a one-time Indian settlement; Petroglyph, the site of ancient rock art outside Albuquerque; Salinas Pueblo Missions, with pueblo ruins and a Spanish mission; and White Sands, a deposit of gypsum sand.

**State parks and monuments.** New Mexico has 40 state parks and 5 state monuments. For detailed information about the parks and monuments, write Superintendent, State Park and Recreation Division, P.O. Box 1147, Santa Fe, NM 87503.
Annual events

January-March
King's Day Dances in most Indian pueblos (January 6); Winter Festival in Red River (January); Winter Ski Fiesta in Santa Fe (late February); Rio Grande Arts and Crafts Festival in Albuquerque (early March); dances at most Indian pueblos (Easter).

April-June
Green Corn Dance at San Felipe Pueblo (May 1); Ralph Edwards Festival in Truth or Consequences (early May); Four-Corners Hot-Air Balloon Fiesta near Farmington (late May); Taos Spring Arts Celebration (May-June); Sandia Classic Hang Gliding Competition in Albuquerque (mid-June).

July-September
Apache Indian Ceremonial in Mescalero (July 4th weekend); Rodeo de Santa Fe (mid-July); Puye Cliff Ceremonial at Santa Clara Pueblo (last Saturday and Sunday in July); Green Corn Dance at Santo Domingo Pueblo (August 4); "Billy the Kid" Pageant in Lincoln (early August); Inter-Tribal Indian Ceremonial in Gallup (mid-August); Santa Fe Indian Market (late August); Great American Duck Race in Deming (late August); Fiesta de Santa Fe (mid-September); New Mexico State Fair in Albuquerque (mid-September); Feast Day in Taos Pueblo (late September).

October-December
The Whole Enchilada Fiesta in Las Cruces (early October); Eastern New Mexico State Fair in Roswell (early October); Navajo Fair in Shiprock (early October); International Balloon Fiesta in Albuquerque (mid-October); Farolito Walk on Canyon Road in Santa Fe (December 24); Christmas Eve Dances in Mission Churches at many Indian pueblos (December 24); Christmas Eve Luminaria Tours in Albuquerque (December 24).
Land regions. New Mexico has four main land regions: (1) the Great Plains, (2) the Rocky Mountains, (3) the Basin and Range Region, and (4) the Colorado Plateau.

The Great Plains of New Mexico are part of the vast Interior Plain that sweeps across North America from Canada to Mexico. In New Mexico, the Great Plains cover roughly the eastern third of the state. They extend from a high plateau in the north to the Pecos River Valley in the south. Streams have cut deep canyons in the plateau as it slopes away from the Rocky Mountains. Cattle and sheep graze there. To the south are dry farming and irrigated agriculture. The eastern edge of the state, south of the Carian River, is called the High Plains or Llano Estacado (Staked Plain). The Llano Estacado also covers much of northwestern Texas (see Texas land regions).

The Rocky Mountains extend into north-central New Mexico from Colorado south to a point near Santa Fe. In winter, deep snow piles up on the mountains. In spring, the snow melts and provides water for irrigated crops in the fertile Rio Grande Valley. The Rio Grande, which rises in Colorado, cuts between ranges of mountains. To the east are the Sangre de Cristo (Blood of Christ) Mountains. Wheeler Peak, 13,161 feet (4,011 meters) high, is the highest point in the state. The Nacimiento and Jemez ranges are west of the river.

The Basin and Range Region covers about a third of the state. It extends south and west from the Rockies to the borders with Arizona and Mexico. This region includes scattered ranges of rugged mountains—the Guadalupe, Mogollon, Organ, Sacramento, and San Andres ranges. Broad desert basins (low places where the streams have no outlet) lie between the mountains. The largest basins are the Jornada del Muerto (Journey of the Dead) and the Tularosa. The Rio Grande flows through the Basin and Range Region.

The Colorado Plateau, in northwestern New Mexico, is a broken country of wide valleys and plains, deep canyons, sharp cliffs, and rugged, lonely, flat-topped hills called mesas. The best-known mesa in the state is Acoma. The Indians built a city on top of Acoma. To the west of Acoma is a 40-mile (64-kilometer) strip of malpais, an area of extinct volcanoes and lava plains. Ship Rock, a steep hill that resembles a ship under full sail, has been a famous landmark in San Juan County for hundreds of years. Ship Rock rises 1,678 feet (511 meters) above the flat land around it. The San Juan Basin lies in the northwest section of the Colorado Plateau. The Continental Divide passes through both the Colorado Plateau and the Basin and Range Region. Streams west of the divide run into the Pacific Ocean. Water east of it runs to the Gulf of Mexico.

Rivers and lakes. The Rio Grande runs like a backbone down the length of New Mexico. At the state's southern boundary it turns east and forms the border.

Sheep graze on a New Mexico ranch. Farmers in the state raise sheep and cattle where low rainfall or rough land prevents crop farming. Ranching is the state's leading agricultural activity.

Land regions of New Mexico

Ken Gillard, Click Chicago
between Texas and Mexico. A series of dams stores water for irrigation. Elephant Butte Dam, near Truth or Consequences, blocks the Rio Grande and forms Elephant Butte Reservoir, New Mexico's largest lake. Its water irrigates land in New Mexico, Texas, and Mexico. Another important river is the Pecos. It rises in the Sangre de Cristo Mountains, and then flows south. The Pecos provides irrigation water for the land around Carlsbad and Roswell. The San Juan River drains the northwest corner of the state. The Canadian River rises in the northeastern part. Its waters are stored for irrigation at the Conchas Dam, near Tucumcari. The Gila River, in the southwest, flows west into Arizona.

New Mexico has few natural lakes. Most famous are the deep Bottomless Lakes, a group of pools near Roswell. Artificially created lakes other than Elephant Butte Reservoir include Abiquiu, Avalon, Bluewater, Caballo, Cochiti, Conchas, El Capitan, El Vado, Heron, McMillan, Navajo, Sumner, and Ute.

**Plant and animal life.** Forests cover about a fourth of New Mexico. Common trees include aspens, cottonwoods, Douglas firs, junipers, piñons (nut pines), ponderosa pines, scrub oaks, spruces, and white firs. The yucca, New Mexico's state flower, grows in most areas. Desert plants include cactus, creosote bush, grama grass, mesquite, white and purple sage, and soapweed. Cattle ranchers guard their livestock from the poisonous locoweed. Wild mountain plants include forget-me-nots, saxifrages, sedges, alpine larkspur, and other flowers.

Animal life is plentiful in New Mexico. Among the larger animals are black bears, coyotes, mountain lions, pronghorn antelope, deer, and elk. Other animals include badgers, beavers, bobcats, chipmunks, foxes, jack rabbits, minks, otters, and prairie dogs.

Among the state's game birds are ducks, grouse, pheasants, quail, and wild turkeys. Many varieties of geese and sandhill cranes migrate to New Mexico for the winter. Common fishes include black bass, catfish, crappies, perch, suckers, and trout. Two kinds of poisonous snakes, the rattlesnake and the coral snake, live in New Mexico. The southwestern desert is the home of such spiders as the tarantula and the black widow.

**Climate.** New Mexico has a dry, warm climate. A person may hang out clothes in the rain knowing the rain will stop soon, and the air will dry the clothes quickly. The state averages less than 20 inches (51 centimeters) of precipitation (rain, melted snow, and other forms of moisture) a year. It varies from over 20 inches in the northern mountains to less than 10 inches (25 centimeters) in the south and central areas. Snow falls throughout the state. The south receives only about 2 inches (5 centimeters) a year. The high mountains may get as much as 300 inches (760 centimeters) of snow each year.

### Average January temperatures

Temperatures vary widely throughout the state during wintertime. The far southern section has the mildest winters.

### Average July temperatures

The state has warm summers. The mildest temperatures occur in the mountainous areas of northern New Mexico.

### Average yearly precipitation

New Mexico has a dry climate. Much of the west receives less than 12 inches (30 centimeters) of rain a year.

---

**WORLD BOOK**
The average July temperature is about 74 °F (23 °C). January temperatures are generally warmer in the south than in the north. The state's average January temperature is 34 °F (1 °C). Day and night temperatures vary widely on the same day. The thin, dry air does not stay warm after sundown because of the high altitude. The lowest temperature recorded in New Mexico was -50 °F (-46 °C) at Gavilan, near Lindrith, on Feb. 1, 1951. The highest temperature was 122 °F (50 °C) near Carlsbad on June 27, 1994.

**Economy**

While New Mexico has limited water resources and large tracts of desert, the state's natural resources continue to play a major role in its economy. Tourism, mining, and agriculture provide valuable jobs for the state's workers.

The state's scenic beauty and reputation as an arts and cultural center attract tourists all year. The state's hand-crafted Indian pottery and jewelry are world famous. Tourists flock to New Mexico's many ski resorts in the winter. Large petroleum and natural gas reserves make New Mexico an important mining state, and cattle ranching provides the most farm income.

Large federal government research laboratories are among New Mexico's leading employers. Electronic products are the state's major type of manufacture.

**Natural resources** include large mineral deposits and rich, renewable resources based on the soil. These include forests, grasses, plants, and animals.

**Minerals.** New Mexico is rich in mined products that supply energy. It has large reserves of natural gas, petroleum, and uranium. The state is the nation's leading producer of potash, a vital fertilizer material, and of perlite. New Mexico has one of the largest copper reserves in the nation. The state also ranks high in the production of gypsum, mica, molybdenum, pumice, salt, and zeolites. Other resources include gold, iron ore, lead, magnetite, manganese, silver, and zinc.

**Soil.** More than half of New Mexico's soil is stony and shallow, and not good for farming. Some desert land contains chemicals that prevent trees from growing. However, this land supports some shrubs, flowers, and grasses. The eastern part of the state has sandy soil.

**Water** is precious in New Mexico, and water resources are extremely important. New Mexico and other Western states have joined with Mexico to share the use of water in various streams. Each area gets a share. For example, Colorado users must allow a certain amount of Rio Grande water to flow into New Mexico. New Mexico's resources include underground water.

New Mexico has 10 major storage projects that help make good use of water. These projects regulate the flow of the Canadian, Pecos, Rio Grande, and San Juan rivers, and that of some of their tributaries.

**Forests** cover about a fourth of the state. There are commercially valuable timberlands in eight mountain areas. The most common trees include the aspen, cottonwood, Douglas-fir, juniper, piñon, ponderosa pine, scrub oak, spruce, and white fir.

---

Computer and electronic equipment is New Mexico's leading manufactured product. These technicians produce microprocessors at an Intel Corporation facility in Rio Rancho. They wear special clothing that prevents dust or hair from getting into the tiny circuits.
Service industries provide the greatest part of New Mexico's gross state product—the total value of all goods and services produced in a state in a year. Many of the service industries are concentrated in the state's metropolitan areas.

New Mexico's leading service industry is community, business, and personal services. This group employs more people than any other industry group in the state. Such services include private health care, motels and ski resorts, engineering companies, private research laboratories, and repair shops. Tourists visiting New Mexico contribute billions of dollars to its economy each year.

Government ranks second in terms of its contribution to New Mexico's gross state product. Federal government research laboratories and military bases play a major role in the state's economy. Los Alamos National Laboratory is a world leader in research of military and nonmilitary uses of nuclear energy. Sandia National Laboratories in Albuquerque is a center of nuclear weapons research. Military bases in New Mexico include Cannon Air Force Base in Clovis, Holloman Air Force Base in Alamogordo, Kirtland Air Force Base near Albuquerque, and White Sands Missile Range in the south-central part of the state. The Bureau of Indian Affairs, a federal government agency, assists the state's Indian population. Government services also include the operation of public schools and hospitals.

Wholesale and retail trade is the state's third-ranking service industry. The wholesale trade of groceries, motor vehicles, and petroleum products is important in New Mexico. Major retail businesses include automobile dealerships, discount stores, and food stores.

Finance, insurance, and real estate ranks next among New Mexico's service industries. Real estate provides the most income for this industry group. New Mexico's rapid population growth has led to the development of many new homes and office buildings. Albuquerque is the chief banking and insurance center in the state.

Transportation, communication, and utilities are the state's fifth-ranking service industry. Oil and gas pipeline companies are a large part of the transportation sector. Telephone companies play an important role in the communications sector. Utilities provide electric, gas, and water service. More information about transportation and communication appears later in this section.

Manufacturing. Goods made in New Mexico have a value added by manufacture of about $10 billion a year. This figure represents the increase in value of raw materials after they become finished products.

Computer and electronic equipment is New Mexico's leading manufactured product by far, accounting for about 80 percent of the state's value added by manufacture. Two major electronics companies, Honeywell and Intel, have large operations in the Albuquerque area. Honeywell's factory makes military communication systems. Intel's plant produces silicon chips for computers. Telephone equipment is another important type of electronic good manufactured in New Mexico.

Other products manufactured in New Mexico include chemicals, clothing, concrete, food products, petroleum products, and printed materials. Large oil refineries operate near Artesia, Farmington, and Gallup. The Albuquerque area is the state's chief manufacturing center.

Mining. New Mexico is a leading state in the annual economic production of gas and oil, and a major producer of a number of minerals. The most valuable are copper, zinc, silver, and lead. Uranium is also produced in New Mexico.

**Economy of New Mexico**

This map shows the economic uses of land in New Mexico and where the leading farm, mineral, and forest products are produced. Major manufacturing centers are shown in red.
value of mined products. Natural gas and petroleum together account for about 80 percent of the state's total income from mined products. Natural gas is produced in northwestern and southeastern New Mexico. Much of New Mexico's gas is sent by pipeline to other states. Lea County is the leading petroleum producer, and San Juan County is the leading natural gas producer.

Copper and potash account for most of New Mexico's income from nonfuel mined products. Copper is mined primarily in Grant County. Potash, an ingredient in many fertilizers, comes mainly from deep underground mines in Lea and Eddy counties in southeastern New Mexico. Large surface mines in the northwest produce most of the state's coal. New Mexico ranks among the leading producers of molybdenum, which is used mainly in making steel alloys. A single mine in Taos County produces all of the state's molybdenum. Uranium is mined in McKinley County. Gold and silver are recovered as by-products of copper processing.

Agriculture. New Mexico has about 16,000 farms and ranches. Farmland covers about 55 percent of the state's land area. Cattle ranching is the leading agricultural activity. Ranchers raise beef cattle in almost every part of the state. Most of the beef cattle are shipped to other states for fattening and slaughtering. Dairy cattle are raised mainly in southern and eastern New Mexico. Sheep ranching is also important. Most of New Mexico's cropland is irrigated. The state's leading crop is hay, used to feed cattle. New Mexico is a leading state in the production of chili peppers and pecans. Other crops include cotton, grain sorghum, onions, and wheat.

Electric power. Power plants that burn coal supply about 70 percent of the electric power generated in New Mexico. Most of the rest comes from plants that burn natural gas. Nearly half the power produced in New Mexico is sold to other states. New Mexico has abundant geothermal energy resources, but they are largely undeveloped.

Transportation. New Mexico has about 60,000 miles (97,000 kilometers) of roads and highways. The first road established by Europeans in what is now the United States—El Camino Real (the Royal Highway)—ran from Santa Fe to Mexico City, Mexico. Spaniards first traveled this route in about 1581. The Santa Fe Trail was opened in 1821 between Missouri and New Mexico. Today, Interstate 25 east of Santa Fe follows this old trail.

Albuquerque International Airport is the state's chief airport. New Mexico's first railroad, the Atchison, Topeka and Santa Fe (now part of Burlington Northern Santa Fe Corporation), began operating in the state in 1878.

Communication. The first Spanish-language newspaper in New Mexico, El Crepúsculo de la Libertad (The Dawn of Liberty), began in 1834 at Santa Fe. The Santa Fe Republican, the first English-language paper, was founded in 1847. Today, the state has about 40 newspapers, with about 15 dailies. The most widely read papers are the Albuquerque Journal, The Albuquerque Tribune, the Las Cruces Sun-News, and The Santa Fe New Mexican.

The state's first radio station, KOB, began broadcasting from Albuquerque in 1922. The first television station, KOB-TV, started regular programming from Albuquerque in 1948. New Mexico has about 100 radio stations and 15 television stations. Cable TV systems and Internet providers serve communities statewide.

Government

Constitution. New Mexico is governed under its original state Constitution. The Constitution was adopted in 1911, a year before New Mexico became a state. It has been amended more than 100 times.

Amendments may be proposed by either house of the state Legislature. They must be approved by a majority of the voters in a regular or special election. Some sections of the Constitution require special majority votes to be amended. These sections guarantee the voting rights and education of Spanish-speaking people.

Amendments to these sections must be approved by three-fourths of the voters in the state and by two-thirds of the voters in each county. A constitutional convention may be called by a two-thirds vote of the Legislature, if a majority of the voters approve. The voters must approve amendments proposed by a constitutional convention.

Executive. New Mexico's governor serves a four-year term. Other executive officers elected to four-year terms are the lieutenant governor, secretary of state, auditor, treasurer, attorney general, and commissioner of public lands. Executive officers may hold office for any number of terms, but not for more than two terms in a row. The 10 members of the State Board of Education are also elected by the people, for six-year terms.

Much of the governor's authority lies in the power of appointment. For example, the governor appoints three of the seven members of the State Board of Finance and is a member of the board as well. The governor also appoints most of the directors or board members who run state agencies and institutions. The governor may veto legislation passed by the state Legislature.

Legislature of New Mexico consists of a 42-member Senate and a 70-member House of Representatives. There are 42 senatorial districts and 70 representative districts. Voters in each senatorial district elect one senator. Voters in each representative district elect one representative. Senators serve four-year terms. Members of the House of Representatives serve two-year terms.

The Legislature meets every year on the third Tuesday in January. The sessions are limited to 60 days in odd-numbered years, and to 30 days in even-numbered years. The governor may call the Legislature into special session. The Legislature may call itself into extraordinary session. The Constitution provides for a referendum, but not for initiative (see Initiative and referendum).

Courts. The state Supreme Court is the highest court. It has five justices elected to eight-year terms. Terms are staggered so an entirely new court is not elected in any one election. Every two years, the justices select a member of the court to be chief justice.

The Court of Appeals has seven judges, who are elected to eight-year staggered terms. Panels made up of three judges hear appellate cases. Most cases that this court hears may be taken to the Supreme Court.

District courts are the state's principal trial courts. New Mexico has 47 district judges elected from 13 judi-
The New Mexico House of Representatives meets in the House chambers in the State Capitol in Santa Fe. Each of the 70 representatives is elected for a two-year term.

cial districts. They hold district court sessions in each of the state’s 33 counties. District judges are elected for six-year terms. They also serve as juvenile judges if the defendant is under 18 years old. Other New Mexico courts include magistrate, metropolitan, and probate courts.

Local government. New Mexico has 33 counties. A city-county council administers Los Alamos County. Each of the other counties is run by a board of commissioners. All commissioners are elected to four-year terms. They may serve two terms in a row but must then wait two years before they can be elected again to any public office. Council members are elected to two-year terms except those in Bernalillo and San Juan counties, who are elected to four-year terms.

State law gives municipalities (towns, villages, or cities) a wide choice of form of government. Most common are the mayor-council, commission, and city manager-commission forms. Cities can adopt their own charters. Alamogordo, Albuquerque, Clovis, Gallup, Las Vegas, Los Alamos, and Silver City have their own. Municipal elections occur every two years.

Revenue. Taxes account for about half of the state government’s general revenue (income). Federal grants and other United States government programs and charges for state government services make up most of the rest. A general sales tax provides the greatest portion of New Mexico’s tax revenue. Other sources of tax income include taxes on personal income, mining, and motor fuels.

Politics. In voter registration, Democrats usually outnumber Republicans by about 2 to 1. The eastern part of New Mexico was settled largely by Southerners, who generally vote for Democrats. In the north-central counties, the Spanish American population has been largely Democratic since the early 1930’s. Centers of Republican strength lie in the northeast, northwest, and central portions of the state. For New Mexico’s electoral votes and voting record in presidential elections, see Electoral College (table).

### History

Indian days. Indians have lived in what is now New Mexico for thousands of years. Stone spearheads found at Folsom and other places indicate that Indians hunted in northeastern New Mexico at least 10,000 years ago. The spearheads are known as Folsom points. See Folsom point.

From about 500 B.C. to A.D. 1200, the Mogollon Indians lived in the valleys in the area of the New Mexico-Arizona border. At first the Mogollon Indians lived in houses dug partly into the ground. Later, they built villages that stood above the ground. See Mogollon.

Another group of ancient Indians lived in the region where New Mexico, Arizona, Utah, and Colorado meet. These Indians were the Anasazi, who had one of the most highly developed civilizations in North America. The Anasazi raised corn and cotton, and tamed wild turkeys. The large birds provided food and clothing. During the winter, the Indians wore robes made of turkey feathers and rabbit fur. Some Anasazi were cliff dwellers and built many-storied apartment houses of closely fitted stones. Many other Anasazi built apartment houses on flat surfaces. One such building, the Pueblo Bonito (pretty village), probably had about 600 or 700 rooms. Sometimes the Anasazi built towns on top of
steep mesas. The Pueblo Indians are the descendants of these people. See Anasazi.

The Navajo and Apache tribes came from the north about A.D. 1500. The Ute and Comanché came a few years later.

**Exploration and settlement.** The first Spanish explorers reached the New Mexico area almost by accident. Álvar Núñez Cabeza de Vaca was a member of a group seeking gold in Florida in 1528. He and others became separated from the expedition's ships. In an attempt to reach New Spain (now Mexico), they sailed on barges to the Texas coast. In 1536, after wandering for eight years, Cabeza de Vaca and three companions—two white men and a black man—reached a settlement near the Pacific coast of New Spain. They told stories of seven cities of great wealth, called the *Seven Cities of Cibola*, to the north. See Cibola, Seven Cities of.

The Spanish were determined to find the seven rich cities. Guided by Cabeza de Vaca's black companion, Estevanico, also called Estéban, a priest named Marcos de Niza made a search in 1539. He claimed the area as a province of Spain. Marcos de Niza also reported that he had seen one of the cities from a distance.

Francisco Vásquez de Coronado, also in search of the seven cities, explored present-day New Mexico and Arizona from 1540 to 1542. But he found only the pueblos of the Indians. Fray Augustín Rodríguez and Captain Francisco Sánchez Chamuscado traveled up the Río Grande from New Spain in 1581. The report of a later explorer, Antonio de Espejo, led to colonization of the region.

The first Spanish colony in New Mexico was established in 1598 at the Pueblo of San Juan de los Cañeros, near the Chama River. The colony was financed and established by Juan de Oñate. He became governor of the province of New Mexico. Oñate was succeeded as governor by Pedro de Peralta, who moved the capital to Santa Fe in 1609 or 1610. Santa Fe is the oldest seat of government in the United States.

The colony had little wealth and grew very slowly. It was kept alive mainly by the efforts of missionaries. Roman Catholic priests from Spain established schools to teach Christianity to the Indians. But repeated quarrels occurred between the church and civil authorities, and between the Spaniards and the Indians.

The Spaniards set up a system of forced labor for the Indians that was almost like slavery. The Spaniards also charged the Indians an annual tax of corn and blankets. In addition, they kept the Indians from worshiping their ancient gods. Popé, an Indian from the San Juan Pueblo, led a revolt in 1680. The Indians killed more than 400 Spaniards, and drove the rest to what is now Juárez, Mexico. The Indians destroyed almost every trace of the Roman Catholic Church.

In 1692, the Spanish governor Diego de Vargas took back the province with little trouble. Four years of scattered fighting broke the power of the Pueblo Indians. The colonists and priests returned to build homes and missions in and near Santa Fe. For 125 years, the Spaniards and Pueblo Indians lived fairly peacefully in this lonely outpost of the Spanish Empire.

**Mexican rule.** Trappers and traders came to New Mexico from the United States during the early 1800's. Spanish officials feared the newcomers, and expelled them or put them in prison. But the Spanish officials were replaced in 1821, after Mexico won its freedom from Spain. New Mexico became a province of Mexico. That same year, William Becknell, an American trader,
New Mexico

Historic New Mexico

Pueblo Bonito was built by Anasazi Indians, ancestors of the Pueblo Indians. The Anasazi began building many-storied houses about A.D. 700.

The Santa Fe Trail opened a new trade route to New Mexico. Trader William Becknell opened the trail in 1821 when he brought the first goods to Santa Fe from Missouri. Stagecoach service started from Independence, Mo., in 1849.

Billy the Kid, a cattle thief and killer in New Mexico, took part in the Lincoln County cattle war. Pat Garrett, the Lincoln County sheriff, killed Billy the Kid in 1881.

Pancho Villa was the leader of a group of Mexican bandits that raided Columbus in 1916, killing 16 people.

Important dates in New Mexico

1540-1542 Francisco Vásquez de Coronado explored New Mexico.
1598 Juan de Oñate founded the first permanent Spanish colony, at San Juan.
1609 or 1610 Governor Pedro de Peralta established Santa Fe.
1680 The Pueblo Indians revolted and drove the Spaniards out of northern New Mexico.
1692 Diego de Vargas reconquered New Mexico for Spain.
1706 Francisco Cuervo y Valdes founded Albuquerque.
1821 Mexico won its independence from Spain, and New Mexico became a province of Mexico. William Becknell opened the Santa Fe Trail.
1846 General Stephen W. Kearny took control of New Mexico during the Mexican War.
1848 Mexico ceded New Mexico to the United States.
1850 Congress created the Territory of New Mexico.
1853 New Mexico acquired part of the Gila Valley.
1862-1864 Colonel Kit Carson defeated the Mescalero Apache and Navajo Indians.
1876 Cattlemen began the Lincoln County War.
1886 The surrender of Geronimo ended the Apache Wars.
1912 New Mexico became the 47th state on January 6.
1916 Mexican bandits raided Columbus.
1922 Geologists discovered oil in the southeastern and northwestern regions of New Mexico.
1945 The first atomic bomb was exploded at Trinity Site near Alamogordo.
1950 Paddy Martinez, a Navajo Indian, found uranium in the northwest region.
1970's Completion of the San Juan-Chama project brought water to north-central New Mexico.
1998 New Mexico celebrated the 400th anniversary of the founding of the colony at San Juan.

WORLD BOOK illustrations by Kevin Chadwick
opened the Santa Fe Trail to bring goods to New Mexico from Missouri. Mexico ruled the area for the next 25 years, a period filled with unrest. In 1837, Mexicans and Indians in New Mexico rebelled against the Mexican government. They executed the governor and seized the Palace of Governors in Santa Fe. A Taos Indian, José Gonzales, was installed as their chief executive. But a month later, Mexico's General Manuel Armijo crushed the rebellion and became governor. In 1841, an expedition from Texas (then an independent country) invaded New Mexico. The Texans claimed the land east of the Rio Grande. However, Mexican troops defeated the invaders and sent them as captives to Mexico City. They were later freed.

The Mexican War. As colonists from the United States pushed west, trouble developed between the United States and Mexico. In 1846, war broke out, and U.S. forces under General Stephen W. Kearny took control of New Mexico with little resistance. The Treaty of Guadalupe Hidalgo ended the war in 1848, and the U.S. took possession of the region. See Mexican War.

Territorial days. In 1850, Congress organized New Mexico as a territory. The territory also included what is now Arizona and parts of present-day Colorado and Nevada. In 1853, the Gadsden Purchase enlarged the territory (see Gadsden Purchase). Mexico sold the United States land south of the Gila River, between the Rio Grande and the Colorado River. New Mexico got its present boundaries in 1863, after Congress organized the territories of Colorado and Arizona.

Early in the Civil War (1861-1865), Confederate forces from Texas captured much of the region, including Albuquerque and Santa Fe. Union forces recaptured the territory in March 1862, after two battles southeast of Santa Fe. The first clash was fought in Apache Canyon, and the second in Glorieta Pass. Between 1862 and 1864, Colonel Kit Carson, a famous frontier scout, led the New Mexicans in forcing both the Mescalero Apache and the Navajo Indian tribes to live on a reservation.

During the late 1870s, cattlemen and other groups fought for political control of Lincoln County. The bitterness burst into open violence with the murder of rancher John G. Tunstall. Billy the Kid and other outlaws took a leading part in the fighting, which became known as the Lincoln County War. General Lew Wallace was appointed territorial governor in 1878. He pardoned the fighters to end the bloodshed. Pat Garrett, the sheriff of Lincoln County, killed Billy the Kid in 1881. Sheriffs, including Garrett, and territorial governors helped establish order during the 1880s.

The Apache Chief Victorio led frequent fierce attacks on settlers from 1879 until his death in 1880. Geronimo, one of the last hostile Apache leaders, spread terror through the area until he surrendered on Sept. 4, 1886. During the late 1880s, after railroads linked the territory to the rest of the nation, New Mexico experienced a cattle and mining boom.

Early statehood. New Mexico became the 47th state on Jan. 6, 1912. It had a population of about 330,000. The people elected William C. McDonald as the first state governor.

Mexican rebels, probably led by Pancho Villa, raided the town of Columbus in 1916, killing 16 Americans. The U.S. Army sent an expedition into Mexico to catch Villa, but it failed. During World War I, New Mexico sent over 17,000 men into the armed forces.

In the early 1920s, a long drought made life difficult for farmers and ranchers. Livestock prices dropped, and the stock owner's financial troubles spread. Banks closed and many people lost their savings. But new businesses developed. Oil was discovered in the 1920s, and huge potash deposits at Carlsbad were opened. In 1930, the famous caverns near Carlsbad became a national park, and the tourist industry grew.

World War II. When the United States entered World War II in 1941, the 200th Coast Artillery, composed of New Mexico soldiers, was in the Philippine Islands. The Japanese overwhelmed the regiment, along with the rest of the U.S. forces on Bataan Peninsula. Many of the soldiers were killed, and others spent over three years in Japanese prison camps. The war ended after U.S. planes dropped two atomic bombs on Japan in August 1945. The bombs had been produced at Los Alamos, a town and laboratory built secretly in the New Mexico mountains. The world's first atomic bomb was exploded at Trinity Site, near Alamogordo, on July 16, 1945.

The mid-1900s. After World War II ended in 1945, the government continued to spend large amounts of money in New Mexico for research. The state's economy and population both grew rapidly as the government provided funds for work on nuclear power develop-

The world's first atomic bomb was exploded at Trinity Site, near Alamogordo, on July 16, 1945. Scientists produced the bomb at the weapons research laboratory in Los Alamos.
ment and experiments with rockets. The economy also was aided by the discovery of uranium in northwestern New Mexico in 1950.

The state's coal industry grew in the mid-1960's. A large coal mine was opened near Raton, and coal-burning electric generating plants were built near Farmington. But production of potash decreased in the Carlsbad area due to competition from Canadian potash mines.

The New Mexico tourist industry continues to grow. Income from tourists almost doubled from the mid-1960's to 1970. Construction and improvement of winter sports resorts helped to increase tourism.

Lack of water has always created problems in New Mexico. Some of these problems were solved with completion of the San Juan-Chama project in the 1970's. This project brings water to north-central New Mexico through tunnels from branches of the San Juan River in the Rocky Mountain area. Reservoirs built near Chama and Abiquiu as part of the project provide recreational facilities and water for irrigation.

Recent developments. Today, New Mexico ranks as a leading center for space and nuclear research. The largest private employer in the state is Sandia National Laboratories of Albuquerque, which conducts research and does engineering work on the uses of nuclear energy. At Los Alamos, government scientists work on many projects involving military and nonmilitary uses of nuclear energy. Military bases and manufacturing for military projects also contribute to the economy.

Although military-related projects continue to play a large role in New Mexico's economy, reductions in U.S. military spending slowed this part of the economy. Substantial reductions took place in the early 1990's after the Soviet Union broke up and the Cold War ended. But the growth of nongovernment industries helped compensate for the military reductions. Tourism has continued to play a strong role in the state's economy into the 1990's. Manufacturing and construction industries in New Mexico experienced growth in the early 1990's. In 1998, New Mexico celebrated the 400th anniversary of the founding of the colony at San Juan.

Level I

Level II

New Mexico, University of, is a state-controlled co-educational school in Albuquerque, New Mexico. It has colleges of architecture and planning, arts and sciences, education, engineering, fine arts, nursing, and pharmacy; schools of law, management, and medicine; and a University College. Students belong to the University College their first year, after which they may enter one of the other colleges. The university also has graduate divisions of public administration and dental programs. The university grants bachelor's, master's, and doctor's degrees. Branch campuses of the University of New Mexico are in Gallup, Los Alamos, and Valencia County, and graduate centers are in Los Alamos and Santa Fe.

The university's Maxwell Museum of Anthropology contains a major collection of objects made by the Anasazi Indians, who were ancestors of the Pueblo Indians. In addition, the Albuquerque campus has museums of biology, geology, and meteoritics; art galleries; and a 2,200-seat concert hall. The University of New Mexico was founded in 1889.

Critically reviewed by the University of New Mexico

New Mexico State University is a coeducational institution in Las Cruces, New Mexico. It has colleges of agriculture and home economics, arts and science, business administration and economics, education, engineering, and human and community services. The graduate school grants master's and doctor's degrees. Cooperative programs in education, engineering, mathematics, physics, and accounting are available. The university also has special research facilities in computing and in plant genetics.

New Mexico State University was founded in 1888 as Las Cruces College, and in 1889 became New Mexico College of Agriculture and Mechanic Arts. The university received its present name in 1960.

Critically reviewed by New Mexico State University

New Netherland was a region in America claimed by the Dutch in the early 1600's. It included parts of what are now Connecticut, Delaware, New Jersey, and New York.

In 1621, merchants in the Netherlands formed the Dutch West India Company to compete with the Spanish Empire, colonize New Netherland, and develop the region's fur trade. Thirty families, sponsored by the trading company, began a Dutch colony at the mouth of the Hudson River in 1624. In 1625, the Dutch settlers founded New Amsterdam (now New York City) there. Peter Minuit, governor (or director-general) of New Netherland, bought Manhattan Island from the Indians in 1626. The Dutch set up trading posts at what are now Albany, New York; Hartford, Connecticut; and Trenton, New Jersey.

The Dutch West India Company attracted settlers from many European countries. About 20 languages were spoken in the colony, and many religions were represented. The Dutch colonists became allies of the Iroquois Indians, and they fought other tribes and neighboring French colonists. By the 1650's, a fierce trading rivalry had built up between the Dutch and the English. In 1664, the English sent a fleet of warships to capture New Netherland for the Duke of York. Many of the Dutch colonists refused to fight, and Governor Peter Stuyvesant was forced to surrender to the English. New Netherland became the English colony of New York.

Joan R. Gundersen

See also Dutch West India Company; New York (History); Stuyvesant, Peter.
New Orleans’s famous attractions include its historic French Quarter and colorful Mardi Gras parades. The lacy iron grillwork that decorates many French Quarter buildings is a trademark of the city. The Mardi Gras festivities end the day before Lent begins.

New Orleans

**New Orleans, AWR lee uhnz, awr LEENZ, or AWR lohnz,** is the largest city in Louisiana and one of the world’s busiest ports. It is also a leading business, cultural, and industrial center of the Southern United States. New Orleans lies along the Mississippi River about 100 miles (160 kilometers) north of where the river flows into the Gulf of Mexico. This location has helped make the city a great shipping center.

Many people call New Orleans *America’s Most Interesting City.* Each year, several million tourists visit New Orleans. The largest crowds come for the annual Mardi Gras celebration, with its spectacular parades and other merry festivities. Tourists are also attracted by the city’s historic French Quarter, much of which has the charm of an old European town. In addition, a large number of visitors come to New Orleans to hear top jazz musicians perform in the city that helped give birth to jazz in the early 1900’s.

New Orleans is the South’s oldest major city. It was founded in 1718 by Jean Baptiste le Moyne, Sieur de Bienville. Bienville was governor of the French colony of Louisiana. He named New Orleans after Philippe, Duke of Orleans, who ruled France for King Louis XV, then a youth. The flags of France, Spain, the Confederate States, and the United States have flown over the city.

Today, New Orleans is a colorful blend of old and new. Most of the historic sites have been preserved.

While urban renewal programs have replaced many decaying structures with striking new buildings. But like many other large U.S. cities, New Orleans faces such problems as crime, poverty, and slums.

**The city**

New Orleans covers 364 square miles (943 square kilometers), including 165 square miles (427 square kilometers) of inland water. The city occupies all of Orleans Parish and has the same boundaries as the parish. In Louisiana, counties are called *parishes.*

New Orleans is often called the *Crescent City* because its original section—the French Quarter—lays along a giant curve in the Mississippi River. Today, the main part of the city lies between the river on the south and Lake Pontchartrain on the north. Much of New Orleans is below sea level and lacks natural drainage. To prevent floods during heavy rainstorms, the city relies on one of the world’s greatest systems of drainage pumps. The system’s 112 pumps can draw off 25 billion gallons (95 billion liters) of water a day. New Orleans has also built about 130 miles (209 kilometers) of walls, called *levees,* in order to help prevent floods. The longest levees lie

_Facts in brief_

**Population:** City—484,674. Metropolitan area—1,337,726.

**Area:** City—364 mi² (943 km²). Metropolitan area—3,400 mi² (8,806 km²), excluding inland water.

**Climate:** Average temperature—January, 54 °F (12 °C); July, 82 °F (28 °C). Average annual precipitation (rainfall, melted snow, and other forms of moisture)—54 inches (137 cm). For the monthly weather, see Louisiana (Climate).

**Government:** Mayor-council. *Terms:*—4 years for the mayor and the seven council members.

**Founded:** 1718. Incorporated as a city in 1805.

*Ralph E. Thayer, the contributor of this article, is Professor of Urban Planning and Public Administration at the University of New Orleans.*
The Louisiana Superdome lies at the edge of downtown New Orleans. The 95,427-seat stadium, the world’s largest indoor arena, is used for conventions, sports events, and trade shows.

along the Mississippi River and Lake Pontchartrain.

Downtown New Orleans borders the east bank of the Mississippi. Most of the city’s residential districts lie west, north, and east of the downtown area. The rest occupy a finger-shaped area on the river’s west bank. This area, known as Algiers, is the only part of New Orleans on the west bank.

Downtown New Orleans includes the French Quarter and the main business district. The French Quarter was named after the French colonists who first settled the area. It is also called the Vieux Carré (pronounced vee yoo cair RAY), meaning Old Square. Most buildings in the French Quarter, however, look more Spanish than French. Terrible fires swept through the area in 1788 and 1794. At that time, Spain ruled Louisiana, and so the rebuilding favored the Spanish style of architecture. This style can be seen in many homes and other buildings with their lovely, landscaped patios and graceful balconies of lacy iron grillwork.

Several of New Orleans’s most historic structures border Jackson Square in the heart of the French Quarter. One landmark, the St. Louis Cathedral, was completed in 1851. It stands between the Presbytère and the Cabildo. The Presbytère, built from 1794 to 1813, was used as a courthouse. The Cabildo, begun in 1795 and completed in 1799, was the seat of the Spanish government in the Louisiana Territory. The United States acquired the territory from France in the Louisiana Purchase of 1803. The official transfer of the land took place in the Cabildo. The Presbytère and the Cabildo are now museums. Fire damaged much of the Cabildo in 1988. However, the museum has been fully restored.

The Pontalba Buildings, two block-long apartment buildings, face each other across Jackson Square. They were built as luxury town houses in 1849 and are among the city’s most fashionable residences. The French Quarter is also known for its nightclubs on Bourbon Street and antique shops on Royal Street. It also has a number of restaurants famous for fine food.

New Orleans’s main business district lies west of the French Quarter. Large department stores stand along Canal Street, the district’s chief shopping area. This broad boulevard is 171 feet (52 meters) wide. The 33-story International Trade Mart rises at the south end of Canal Street. Many firms that deal in foreign trade have offices in the Trade Mart. A public observation deck at the top of the building offers a spectacular view of the city and the Mississippi River.

Many modern high-rise office buildings and hotels line Poydras Street between the riverfront and the gigantic Louisiana Superdome. The 95,427-seat Superdome, the world’s largest indoor stadium, is used for sports events, conventions, and trade shows. City Hall stands in the nearby Civic Center.

Residential districts. West of downtown New Orleans is a large residential area known as Uptown. It includes some of the city’s oldest neighborhoods. The most famous one is the Garden District, with its majestic old mansions and beautiful gardens. Americans who came to New Orleans after the Louisiana Purchase in 1803 developed the Garden District. Also in Uptown are Tulane University, Loyola University, and 340-acre (138-hectare) Audubon Park.

City Park and a number of attractive communities along the Lake Pontchartrain shore cover much of northern New Orleans. City Park occupies 1,500 acres (607 hectares) and is one of the nation’s largest city-owned parks. The New Orleans Museum of Art is in the park. Lake Vista, the oldest community on the lakefront, was laid out during the 1930s. This area remains one of the city’s finest examples of urban planning with its ranch-style houses surrounded by a belt of parks. New Orleans Lakefront Airport and the University of New Orleans also lie on the lakefront.

Most of New Orleans’s newest neighborhoods have been built in the northeastern part of the city, commonly called New Orleans East. Large-scale development began there during the 1960s.

New Orleans lies in southeastern Louisiana.
The metropolitan area of New Orleans covers 3,400 square miles (8,806 square kilometers). It extends over eight parishes—Jefferson, Orleans, Plaquemines, St. Bernard, St. Charles, St. James, St. John the Baptist, and St. Tammany. More than a million people, about a third of Louisiana's people, live in this area. New Orleans's largest suburb, Metairie, lies west of the city and has a population of 146,136. Fast-growing suburbs have sprung up along the Mississippi between New Orleans and Baton Rouge with the development of large industries. Suburbs north of Lake Pontchartrain are also growing.

People

African Americans make up more than two-thirds of New Orleans's population. Whites and a small number of Hispanics and Asians account for most of the rest. Many white Orleanians are descendants of European immigrants who came to the city to find opportunity and freedom during the 1800's and early 1900's. Many other Orleanians arrived from Latin-American countries during the 1900's. Large numbers of blacks have lived in the city since the first slaves were brought in the early 1700's. In addition, many free blacks immigrated from the Dominican Republic during the 1600's and 1700's. The New Orleans metropolitan area has experienced a shift in population common to other major urban cen-
Ethnic groups. Nearly all the early African American residents of New Orleans came from Africa as slaves. They worked on farms and plantations in and near the city. In the early 1900's, African American musicians made New Orleans a world-famous center of jazz. Black jazz bands still follow a New Orleans custom and play in black funeral processions to and from cemeteries. See Jazz (Early jazz).

Today, more than 325,000 African Americans live in New Orleans and make up the city's largest ethnic group. Many of them are poor and live in mainly black communities near the downtown area. However, there is a growing African American middle class. Many of these people live in eastern New Orleans.

Other groups of Orleanians include those of Cuban, French, German, Irish, Italian, Mexican, Polish, or Vietnamese ancestry. Many residents who came from Latin America live southeast of the downtown area.

The descendants of New Orleans's early French and Spanish residents are known as Creoles. The term Creole comes from the Spanish word criollo, which means native to the place. The Creole influence is still strong in New Orleans. For example, on All Saints' Day (November 1), a citywide holiday that honors the dead, many Orleanians follow the Creole tradition of going to the cemetery in family groups. Creole cooking, a spicy blend of French and Spanish dishes, remains popular in restaurants throughout New Orleans.

Housing. About 40 percent of New Orleans's families own their homes. Most of the rest rent apartments. New high-rise apartment buildings have been erected in various parts of New Orleans. But about half the city's housing was built before 1940. In fact, much of the housing dates from the 1800's. Many of the older homes, especially those in the French Quarter and the Garden District, have been beautifully restored. But much other housing, greatly in need of repair, is neglected because of high repair costs and low personal incomes.

Education. New Orleans has about 140 public schools. About 90 percent of the public school students are blacks. The New Orleans metropolitan area also has about 125 Roman Catholic schools in the city and suburbs. There are also a number of other church-supported and private schools.

The University of New Orleans, the city's largest university, is part of the Louisiana State University system. Tulane University is New Orleans's oldest institution of higher learning. It was founded in 1834. Other universities and colleges in New Orleans include Dillard University; Loyola University New Orleans; New Orleans Baptist Theological Seminary; Notre Dame Seminary Graduate School of Theology; Our Lady of Holy Cross College; Southern University of New Orleans; and Xavier University.

The arts. New Orleans is a leading cultural center of the South. The New Orleans Theatre of the Performing Arts houses the New Orleans Opera House Association. The Louisiana Philharmonic, a symphony orchestra completely owned by its musicians, performs in the Orpheum Theatre.

New Orleans has been known for its jazz ever since the city helped give birth to the music in the early 1900's. Black musicians and a number of white musicians helped to develop jazz in the bars and nightclubs on Basin, Rampart, and other streets in the French Quarter. Today, old New Orleans-style jazz is still played in many places in the city. One of the most famous places
New Orleans

is Preservation Hall, a small building where fans sit on wooden benches or stand to hear jazz concerts.

Le Petit Théâtre du Vieux Carré is one of the city's best-known professional theater companies. The Dashiki Project Theatre is an outstanding black company.

Libraries and museums. The New Orleans Public Library operates a main library and several branches. Tulane University has an outstanding collection of books on Louisiana history. Tulane is also the home of the Amistad Collection, a group of books and other materials about black life and culture. In addition to public and university libraries, the historic New Orleans Collection is one of the finest repositories of material about the development of Louisiana and the South.

The New Orleans Museum of Art has a fine display of Spanish colonial paintings and decorative art. The Louisiana State Museum operates eight historic buildings in New Orleans, including the Cabildo and Madame John’s Legacy, a beautifully restored house dating from the early 1700’s. Other New Orleans museums include the Moss-Pitot House, a former plantation; the Confederate Memorial Museum; the National D-Day Museum; and the Old U.S. Mint, which features jazz and Mardi Gras memorabilia.

Jean Lafitte National Historical Park and Preserve includes a large area of wetlands and the site of the Battle of New Orleans. A visitor center features displays about the battle, which was the last clash of the War of 1812.

Recreation. New Orleans has over 100 parks. The two largest parks, City Park and Audubon Park, were plantations in the 1800’s. City Park includes a bandstand and the 27,000-seat Municipal Stadium. Audubon Park’s attractions include a large zoo. The Aquarium of the Americas, a large aquarium, stands in the French Quarter along the Mississippi River. Lake Pontchartrain and other nearby lakes are popular for boating, fishing, and sailing. The Bayou Sauvage National Wildlife Refuge in eastern New Orleans is an appealing outdoor attraction.

The city has two major league professional sports teams. It is the home of the New Orleans Saints of the National Football League and the New Orleans Hornets of the National Basketball Association.

Annual events. Every year, about a million visitors attend New Orleans's exciting Mardi Gras festival in February or March. The celebration climaxes the city's carnival season, which begins in January. Mardi Gras activity lasts about two weeks and ends on Shrove Tuesday, the day before the Christian observance of Lent starts. It features joyful parades and elaborate costume balls sponsored by private carnival organizations known as krewes. On Shrove Tuesday, also called Mardi Gras Day, the king of the Rex krewe leads a merry parade of several hundred floats. Brightly costumed riders on the floats toss beads, toys, and imitation gold coins called doubloons to eager crowds.

Another popular annual event in New Orleans is the Spring Fiesta, held in April or May. It includes guided tours through charming old houses in the French Quarter and the Garden District. The Jazz and Heritage Festival is another popular spring event. New Orleans hosts the annual Sugar Bowl football game on or near New Year’s Day. The game, held in the Superdome, features two of the nation’s top college teams.

Social problems. The chief social problems in New Orleans, as in most other large U.S. cities, include poverty, slums, and crime. Nearly a fifth of the city’s families are poor. Most of the needy have little education and hold low-paying jobs or are unemployed. Many of the unemployed have not completed high school and lack the skills needed for jobs. Deteriorating housing in low-income areas is a serious problem. Many of the poor are forced to live in overcrowded, run-down housing. The city has been unable to finance much new housing. High unemployment and crime rates especially trouble the city’s black neighborhoods and contribute to racial tension. But New Orleans also has many suc-

A lovely terrace is the setting for this restaurant in New Orleans. Many of the city’s restaurants are famous for fine food and feature Creole cooking, a blend of French and Spanish dishes.

St. Louis Cathedral faces Jackson Square in the heart of the French Quarter. The towering spires of the church have made it a New Orleans landmark. The building dates from 1851.
Shipbuilding is one of the leading industries in the New Orleans metropolitan area. The Avondale Shipyard of Jefferson Parish, shown here, is a major U.S. shipbuilding center.

**Economy**

New Orleans's economy depends heavily on shipping and tourism. The Port of New Orleans ranks among the world's busiest seaports. The French Quarter helps attract more than 700 conventions to New Orleans yearly. In addition, the city is one of the South's major centers of business, industry, and transportation.

**Trade and finance.** The Port of New Orleans handles about 143 million tons (132 million metric tons) of cargo a year. About 5,000 ships from about 60 nations dock at the busy port annually. The chief exports are grain and other foods from the midwestern United States and petroleum products. The leading imports include chemicals, cocoa beans, coffee, and petroleum. The port handles more trade with Latin America than does any other U.S. port.

New Orleans is also a busy port for barges. The barges use the nation's two main inland waterways, the Mississippi River and the Gulf Intracoastal Waterway, which meet at New Orleans. The port of New Orleans handles about 50,000 barges yearly.

The New Orleans metropolitan area is one of the South's chief centers of retail and wholesale trade. It has about 8,500 retail firms and over 2,000 wholesale firms.

The New Orleans area is also a financial center. Many commercial banks and savings and loan associations operate in the area. Their loans help finance business expansion projects and other civic developments. The Sixth Federal Reserve District Bank operates a branch bank in New Orleans.

**Industry.** The New Orleans metropolitan area has about 1,000 manufacturing plants. They employ about 12 percent of the area's workers and produce more than $1 billion worth of goods yearly.

At the Michoud Assembly Facility, several companies produce equipment for the United States space program. Michoud made the Saturn 5 rocket that launched the Apollo 11 astronauts to the moon in 1969. In the 1980's, a huge new industrial center, the Almonaster-Michoud Industrial District (now called the New Orleans Business and Industrial District), was begun. It was built around the Michoud Assembly Facility. See the Recent developments section of this article for more details. The Avondale Shipyard, in Jefferson Parish, is one of the nation's largest shipbuilding centers. Other leading industries in the area make food products, petrochemicals, petroleum products, and primary metals.

**Transportation.** Barges and oceangoing ships dock at wharves on the Mississippi River, the Inner Harbor Navigation Canal, and the Mississippi River-Gulf Outlet. The Navigation Canal links the Mississippi and Lake Pontchartrain. The 76-mile (122-kilometer) Gulf Outlet gives shippers a 44-mile (71-kilometer) short cut between New Orleans and the Gulf of Mexico.

Louis Armstrong New Orleans International Airport, in the nearby city of Kenner, serves many commercial airlines. Private aircraft use New Orleans Lakefront Airport. Many trucking companies and several passenger and freight rail lines also serve the city. The Lake Pontchartrain Causeway, the world's longest bridge, extends about 29 miles (47 kilometers). It spans the lake and links New Orleans and its northern suburbs.

**Communication.** New Orleans has one daily newspaper, *The Times-Picayune*. It has the largest circulation of Louisiana's daily newspapers. Several television stations and about 30 radio stations serve the city.

**Government**

The city has a mayor-council form of government. Voters elect the mayor and the seven members of the City Council to four-year terms. The mayor may serve any number of terms but not more than two in a row.

The mayor appoints a chief administrative officer to help direct the city government. The mayor also plans civic improvements. The council makes the city's laws. The mayor may veto bills passed by the council. However, any bill the mayor vetoes may still become law if at least five council members vote to repass it.

A sales tax is the city government's largest source of local revenue. But New Orleans, like other big cities, does not raise enough money from local taxes to pay for the increasing costs of services and improvements. As a result, the city depends on the state and federal governments for about one-third of its revenue.

**New Orleans's flag** was adopted in 1918. The three stripes symbolize democracy. The fleurs-de-lis stand for the city's French heritage.

**The city seal** dates from 1852. The Indians honor the first inhabitants of the New Orleans area. The alligator represents the city's swamps.
History

Chickasaw, Choctaw, and Natchez Indians lived in what is now the New Orleans area before Europeans arrived. In 1682, the French explorer René-Robert Cavelier, Sieur de La Salle, sailed down the Mississippi River from the Great Lakes region. He claimed the entire Mississippi Valley for France.

French and Spanish rule. Sieur de Bienville founded New Orleans in 1718. In 1722, he made it the capital of the French colony of Louisiana, which covered the central third of the present-day United States.

In 1762, King Louis XV of France gave Louisiana to his cousin, King Charles III of Spain. The French Orleanians disliked the first Spanish governor of Louisiana, Antonio de Ulloa, and drove him from the city in 1768. But in 1769, soldiers arrived from Spain and restored Spanish rule in New Orleans.

The worst fire in what is now Louisiana broke out in New Orleans on March 21, 1788. It started in a house on Chartres Street and destroyed over 850 buildings. Rebuilding was underway when a fire swept through 200 more structures in 1794.

In 1800, France secretly regained the Louisiana region from Spain but did not reveal the fact until March 1803. The next month, France sold Louisiana to the United States. On November 30, in preparation for the region's official transfer, the French took down the Spanish flag that still waved over New Orleans and raised the French flag. On December 20, the American flag became the third flag to fly over the city in less than a month.

The early 1800's. In 1805, New Orleans was incorporated as a city. Louisiana joined the Union in 1812, and New Orleans became the state capital. Also in 1812, the steamboat New Orleans arrived at New Orleans after sailing down the Ohio and Mississippi rivers from Pittsburgh. It was the first steamer to navigate the Mississippi. River trade soon boomed at New Orleans.

During the War of 1812, British troops tried to capture New Orleans. The British sought the aid of Jean Lafitte, leader of a pirate band based near the city. But Lafitte joined the American forces that were defending New Orleans. General Andrew Jackson commanded the U.S. troops. Jackson’s army and Lafitte’s pirates defeated the British in the Battle of New Orleans on Jan. 8, 1815. See War of 1812 (The Needless Battle).

After the war, river trade brought increasing wealth to New Orleans. The city thrived as a cotton port and slave-trading center. The state capital was moved to Donaldsonville in 1830. But New Orleans again served as the capital from 1831 until 1849, when Baton Rouge became the capital. New Orleans held its first Mardi Gras celebration in 1838.

The Paris of America. By 1840, New Orleans had a population of 102,193 and was the nation’s fourth largest city. In the mid-1800’s, it attracted thousands of immigrants from Germany and Ireland. Professional opera and theater companies thrived in New Orleans during this period, and the lively and glamorous city became known as the Paris of America.

During the mid-1800’s, New Orleans also gained a reputation as an unhealthy city. In 1832, a yellow fever epidemic swept through the city, taking about 7,700 lives. Doctors did not know that mosquitoes, which thrived in the swampy New Orleans area, were the chief carriers of the disease. The worst yellow fever epidemic in United States history hit New Orleans in 1853. It killed more than 11,000 people.

The Civil War and Reconstruction. In 1861, Louisiana withdrew from the Union and joined the Confederate States against the North in the Civil War. New Orleans’s importance as a port made it a chief target of the Union forces. In April 1862, a Union fleet commanded by Captain David Farragut sailed up the Mississippi from the Gulf of Mexico. After bombarding several forts, the fleet reached New Orleans and forced it to surrender on May 1. General Benjamin F. Butler took charge of the city and made it the Union capital of Louisiana.

Union troops remained in New Orleans during the Reconstruction period after the war. Blacks and North-

New Orleans, Battle of. See Jackson, Andrew (Glory at New Orleans); Lafitte, Jean; War of 1812.

New South Wales is the oldest state in Australia.
More people live in New South Wales than in any other Australian state. The state is located on the east coast of the Australian continent. Sydney is the capital and largest city of New South Wales (see Australia [political map]).

The land. New South Wales has an area of 309,500 square miles (801,600 square kilometers). Its coast consists of many rugged cliffs. Some of these cliffs form rocky headlands that enclose good harbors. Sandy beaches line parts of the coast. To the west, a narrow expanse of fertile land leads to the mountains of the Great Dividing Range. The highest peak in Australia, 7,310-foot (2,228-meter) Mount Kosciusko, is part of this range.

Grassy plains lie west of the mountains.
The state has a mild climate. Temperatures average about 50 °F (10 °C) in July and 75 °F (24 °C) in January. Average annual rainfall ranges from 80 inches (200 centimeters) in the eastern highlands to less than 10 inches (25 centimeters) on the western plains.

The people. Most of the 6,038,696 people of New South Wales are of British descent. However, many people from other parts of Europe migrated to New South Wales after World War II ended in 1945, and many Asian immigrants have arrived since the 1970's. About 100,000 Aborigines, descendants of the earliest inhabitants of Australia, live in the state. About three-fifths of the state's population lives in or near Sydney.

Economy. Farmland lies on the coastal plain, in the foothills of the Great Dividing Range, and on the plains west of the mountains. Irrigation systems supply water to many inland areas. Grazing is an important part of the state's rural income. About a third of Australia's sheep are raised in New South Wales. Wheat accounts for almost half the crop production in the state. Other products include bananas and citrus fruits, other grains, potatoes, sugar, and tobacco.

About a fifth of the value of Australia's mineral production comes from New South Wales. Coal ranks as the state's leading mineral product. Australia's first gold discovery was made in New South Wales in 1851. Other important minerals in the state include copper, iron, lead, magnesite, opals, silver, tin, and zinc.

Most of the workers in New South Wales are employed in manufacturing. The state has more than 10,000 factories, chiefly in Sydney, Newcastle, and Wollongong. The leading manufactured goods include chemicals, clothing, fertilizers, glassware, machinery, paper, raw and processed steel and copper, processed foods, and textiles. The state's major exports include coal; raw wool and cotton; such cereals as wheat, rice, and barley; and meat. It's chief imports are manufactured goods.

Education. Children from 6 through 15 years of age must attend school. About 760,000 students attend state-operated public schools, and about 264,000 children attend nongovernmental schools. The University of Sydney has about 18,000 students. Other universities of the state include Macquarie University, the University of Newcastle, the University of New England, and the University of New South Wales.

Government. A governor with limited powers represents the British monarch in New South Wales. The actual head of state is the premier. The premier is assisted by a Cabinet of ministers, who head government departments. The state parliament has a 42-member Legislative Council and 93-member Legislative Assembly.

History. In 1770, the British navigator James Cook and his crew aboard the Endeavour became the first Europeans to reach the area. In 1788, Captain Arthur Phillip landed at Port Jackson in New South Wales with a group of convicts and soldiers to guard them. They founded the first white settlement in Australia. At that time, New South Wales was the name used for the eastern part of Australia and included land that is now the states of Queensland, Victoria, and part of South Australia. Free settlers began to arrive in the early 1800's. Convict immigration to New South Wales ended in 1840. In 1851, the British gave Australian colonies the right to govern themselves in most matters. The colony became completely self-governing in 1856.

In 1901, New South Wales became one of the six states of the Commonwealth of Australia. In 1911, the state began a transfer of land to the federal government to form the Australian Capital Territory, which covers 911 square miles (2,359 square kilometers). Canberra, the national capital, is in the territory.

See also Australia (History); Canberra; Murray River; Sydney; Wollongong.

New Sweden was the only Swedish colony in America. It extended along the Delaware River from the mouth of Delaware Bay to about what is now Trenton, N.J. Swedish settlers founded the colony in 1638 and built Fort Christina at what is now Wilmington, Del. New Sweden was a mildly successful fur-trading colony. About 350 farmers and fur traders lived there. The Dutch protested the existence of New Sweden because the land lay within the Dutch territory of New Netherland. In 1655, Peter Stuyvesant, governor of New Netherland, led a military expedition against New Sweden and forced its surrender.

Oliver A. Rink

See also Delaware (History).
New Testament is the second part of the Christian Bible. The word testament means covenant or agreement. Christians call the first part of the Bible the Old Testament because it is a record of the covenant made by God with the people of Israel long before the writing of the New Testament. The New Testament is the record of a new covenant made by God with humanity through the life, death, and Resurrection of Jesus Christ.

Contents of the New Testament

Books. The New Testament is about one-fourth the length of the Old Testament and consists of 27 individual writings called books. The first four books are the Gospels according to Matthew, Mark, Luke, and John. The Gospels are four different accounts of the words and deeds of Jesus. The authors wrote the Gospels to express their faith in Jesus.

The Acts of the Apostles is a continuation of the Gospel of Luke. It tells the story of the expansion of the early church. Twenty-one documents called Epistles (letters) follow. Thirteen of the Epistles claim to be letters from Saint Paul. Some of the remaining eight are anonymous. Others claim to be letters from the early church leaders Saint Peter, Saint James, and Saint Jude. The New Testament ends with Revelation, also called the Apocalypse.

The 27 books make up the canon of the New Testament—that is, the books that Christians consider to be authoritative scripture. Early Christians produced many other writings that varied in value and authority. These included fanciful gospels and acts designed to fill in the details of the life of Jesus and His apostles. Such writings are now known as apocryphal works. In addition, the early church fathers wrote letters, defenses of Christian faith, and refutations of heresy. By A.D. 400, church scholars regarded the present books of the New Testament as authoritative scripture. Later, church councils ratified these decisions regarding the canon.

Writing the New Testament. The books of the New Testament were written during the period from about A.D. 50 to about 125. The original language of the New Testament is the common Greek widely used at this time. The Greek in the New Testament includes some Hebrew or Aramaic phrases and idioms. These borrowed words may reflect the use of Hebrew or Aramaic by Jesus and His earliest followers.

Dating the New Testament

It is impossible to give definite dates for all the events in the New Testament, just as it is impossible to give definite dates for many other incidents in ancient history. But scholars have been able to set approximate dates by connecting Bible narratives with known historical facts.

The birth of Jesus. Matthew 2:1 indicates that Jesus was born while Herod the Great ruled Palestine (see also Luke 1:5, 26). Because Herod died in 4 B.C., this is the latest possible date for the birth of Jesus. Our current system of dating events from the birth of Jesus was introduced in the A.D. 500's. The person who created the system miscalculated the year of Jesus’s birth. The Christian Era is indicated by the Latin words anno Domini, which mean in the year of our Lord. The abbreviation A.D. is written before the year.

Nothing in the Bible states the day or month of Jesus’s birth. However, December 25 comes about the time of the year called the winter solstice. At this time, the hours of daylight begin to lengthen as winter becomes spring. The date serves as a symbol of the new life that came to the world when Jesus was born.

The public ministry of Jesus. According to Luke 3:1, John the Baptist began preaching in the 15th year of the Emperor Tiberius, which would be A.D. 28. Because all four Gospels agree that Jesus’s public ministry began after that of John, A.D. 28 is the earliest possible date for the start of Jesus’s ministry. According to Luke 3:23, Jesus was about 30 years old at this time. None of the Gospels state how long Jesus’s ministry lasted. The Gospels of Matthew, Mark, and Luke refer to only one celebration of the annual Passover holiday during Jesus’s adult life,
the one at the time of His Crucifixion. This reference seems to imply that Jesus’s public ministry lasted about one year. However, the Gospel of John mentions three Passovers, implying that Jesus’s ministry lasted about three years.

The Crucifixion. All the Gospels imply that Jesus was crucified on a Friday. All except John tell that this Friday was the day of Passover. According to John, the Crucifixion occurred on the day before Passover, and in that year Passover fell on the Sabbath (Saturday in the Jewish religion). If John is correct, the Crucifixion probably occurred in either A.D. 30 or 33, because Passover fell on the Sabbath in these two years.

The life of Paul. According to Acts 18:12-17, Paul was put on trial before the Roman governor Gallio in Corinth. An inscription found at Delphi enables historians to identify A.D. 51-52 as the year Gallio held office and thus the year Paul appeared before him. With this date as a starting point, historians can use other information in Acts and the Epistles of Paul to determine dates for other events in Paul’s life.

Paul’s conversion to Christianity occurred shortly after the Crucifixion and Resurrection of Jesus. In the midst of his extensive missionary journeys, Paul met with the leaders of the Jerusalem church in A.D. 48 (Galatians 2:1-10; Acts 15:1-29). Paul was arrested in Jerusalem in about A.D. 57 while Felix was the Roman governor of Judea. When Festus became governor two years later, Paul was taken to Rome, where he remained in custody for two more years.

Paul probably was killed during the reign of the Emperor Nero (A.D. 54-68). Historians know that Nero put a number of Christians to death after the burning of Rome to turn people’s suspicions away from himself.

Critical studies of the New Testament

Scholarly study of the New Testament is sometimes called criticism. Biblical criticism is divided into two classes, textual criticism and interpretative criticism.

Textual criticism. The original manuscripts of the books of the New Testament, as they were written by the early Christians, have all been lost. Only copies remain. The earliest copies date from the A.D. 100’s. Thousands of later copies exist. Many variations of wording occur in the old copies, though the variations in the Greek manuscript rarely affect the meaning of a passage. However, these differences make it difficult to determine the original wording of some passages.

Textual criticism is concerned with the recovery of the author’s own wording, before copies were made. The process of making copies led to errors, most of which were accidental. With much research and comparison, scholars have put together the many variations of wording found in the copies of the Greek New Testament.

Textual critics also include the variations that underlie the early translations of the New Testament into other languages, such as Latin, the Syriac language of Syria, and the Coptic language of Egypt. In addition, critics include in their research quotations from the New Testament used by early church fathers.

Efforts to determine original wording through careful study and comparison have sometimes met with opposition. But most church officials now accept such studies as a necessary first step in determining the purpose and the original meaning of the Biblical writings.

Interpretative criticism covers a broader field than textual criticism. Interpretative critics analyze the Bible by comparing one passage with another. They also compare statements in the Bible with literary and historical works of the same time. They examine the literary form of Biblical writings. Through such studies, they attempt to establish what the Biblical writings meant to their original authors and readers, and what they mean for Christians today.

Interpretative critics often find a different meaning in the Bible than those who have not studied it in this way. Such an understanding of the Bible is unsettling for some Christians. Some interpretations advanced by critics have been rejected as incompatible with Christian faith. However, most Christians believe that many good results have come from a wise and unprejudiced study of the Bible. The most respected schools of religious studies teach the New Testament in the light of all that modern learning and scholarship have achieved.

New Thought is a philosophical and religious movement that originated in the United States during the mid-1800’s. Supporters of New Thought believe that the human mind is superior to all material conditions and circumstances. They assert that each person is an individualized center of God, and that God is immediately accessible to people through the power of the mind. Accordingly, a person can solve any problem by properly applying mental force. New Thought resembles the ideas of Ralph Waldo Emerson, an American transcendentalist philosopher (see Transcendentalism).

Phineas Quimby and his principal disciples, Julius Dresser and Warren Felt Evans, were early leaders of the New Thought movement. They developed theories of mental healing. They argued that sickness is a wrong belief and can be eliminated by channeling the power of the mind toward the correct idea of health. Mary Baker Eddy, the founder of Christian Science, was influenced by Quimby’s ideas.

New town. See City (Future cities); City planning (Building new communities); Tapiola.

New Westminster (pop. 54,650) is a city in southwestern British Columbia. It lies on the Fraser River, 12 miles (19 kilometers) southeast of downtown Vancouver. For the location of New Westminster, see British Columbia (political map).

The Royal Columbian Hospital is New Westminster’s largest employer. Other employers include mills that produce softwood lumber, pulp and paper, and shingles. Many of New Westminster’s people work in nearby Vancouver, British Columbia’s largest city.

The British Army’s Royal Engineers began laying out
the city in 1858. The city was founded in 1859 and was named Queensborough, after Queen Victoria of Britain. Later in 1859, the queen renamed it New Westminster, after the English town of Westminster (now part of Greater London). New Westminster served as the capital of the colony of British Columbia from 1859 to 1868. In 1860, it became British Columbia's first incorporated city. Fire destroyed the city's main business district in 1898. The district was soon rebuilt. New Westminster has a mayor-council form of government. Graeme Wynn

**New World** is another name for the Western Hemisphere, which includes the continents of North America and South America. See **Old World; Hemisphere**.

**New Year's Day** is the first day of the calendar year. People in almost every country celebrate this day as a holiday. The celebrations are both festive and serious. Many people make New Year's resolutions to break bad habits or to start good ones. Some think about how they have lived during the past year and look forward to the next 12 months.

**Early customs**. Many ancient peoples started the year at harvesttime. They performed rituals to do away with the past and purify themselves for the new year. For example, some people put out the fires they were using and started new ones.

In early times, the ancient Romans gave each other New Year's gifts of branches from sacred trees. In later years, they gave gold-covered nuts or coins imprinted with pictures of Janus, the god of gates, doors, and beginnings. January was named after Janus, who had two faces—one looking forward and the other looking backward. In addition to giving gifts to each other, the Romans also brought gifts to the emperor. The emperors eventually began to demand such gifts. But the Christian church outlawed this custom and certain other pagan New Year's practices in A.D. 567.

The ancient Persians gave New Year's gifts of eggs, which symbolized productivity. The Celtic priests of what is now England gave the people branches of mistletoe, which was considered sacred.

The Celts took over many New Year's customs from the Romans, who invaded the British Isles in A.D. 43. By the 1200's, English rulers had revived the Roman custom of asking their subjects for New Year's presents. Common presents included jewelry and gold. Queen Elizabeth I acquired a large collection of richly embroidered and jeweled gloves through this custom. English husbands gave their wives money on New Year's Day to buy pins and other articles. This custom disappeared in the 1800's. However, the term *pin money* still means small amounts of spending money.

Many American colonists in New England celebrated the new year by firing guns into the air and shouting. They also visited taverns and houses to ask for drinks. Other colonists attended church services. Some people held open house, welcoming all visitors and feeding them generously.

Another old custom involved using the Bible to predict what would happen in the new year. People chose a passage of the Bible at random. Then they applied the passage to the coming months of the new year.

**Modern customs** on New Year's Day include visiting friends and relatives; giving gifts; attending religious services; and making noise with guns, horns, bells, and other devices. Children in Belgium write their parents New Year's messages on decorated paper. The children read the messages to their families on New Year's Day. The Chinese New Year begins between January 21 and February 20. The celebration lasts four days. On the last night, people dress as dragons to frighten and delight the children. In Japan, many people worship on New Year's Day.

In the United States, many people go to New Year's Eve parties. Crowds gather in Times Square in New York City, on State Street in Chicago, and in other public places. At midnight, bells ring, sirens sound, firecrackers explode, and everyone shouts, "Happy New Year!" People also drink a toast to the new year and sing "Auld Lang Syne" ("see Auld Lang Syne").

On New Year's Day, many people in the United States visit relatives, attend religious services, or watch football games on television. Some people attend parades, such as the Tournament of Roses Parade in Pasadena, California, and the Mummers' Parade in Philadelphia.

**The date of New Year's.** The early Roman calendar used March 1 as New Year's Day. Later, the ancient Romans made January 1 the beginning of the year.

During the Middle Ages, most European countries used March 25, a Christian holiday called Annunciation Day, to start the year. By 1600, many Western nations had adopted a revised calendar called the Gregorian calendar. This calendar, the one used today, restored January 1 as New Year's Day. Britain and its colonies in America adopted it in 1752.

Many people celebrate the new year on dates established by their religion. For example, the Jewish New Year, a solemn occasion called Rosh Ha-Shanah, is observed during September or early October (see Rosh Ha-Shanah). Hindus in different parts of India celebrate the new year on various dates. Muslims use a calendar that has 354 days in most years. As a result, the Muslim New Year falls on different dates from year to year on the Gregorian calendar. Robert J. Myers
New York  The Empire State

New York is a leading center of banking, communication, and finance in the United States. It is also a leader in wholesale and retail trade and in manufacturing. According to the 2000 census, New York ranked as the nation's third-largest state in population. Only California and Texas had more people. The capital of New York is Albany.

Much of the state's greatness lies in huge, exciting New York City. New York City is the largest city in the United States, and it ranks as one of the largest cities in the world. It is one of the world's leading centers of business. Its large number of theaters, museums, and musical organizations make it a major cultural center. New York City is a busy seaport. In its harbor stands the Statue of Liberty, long a symbol of freedom to people in all parts of the world. As the headquarters of the United Nations, New York City can be called the "capital of the world."

The contributors of this article are Adam W. Burnett, Associate Professor of Geography at Colgate University, and Milton M. Klein, Editor of The Empire State: A History of New York.

The state's factories turn out an incredible variety of products, from industrial machinery to fine jewelry. New York state is a leading producer in the United States of chemicals, photographic equipment, heating and cooling machinery, computer microchips, electronic components, and bakery products. New York City ranks as the largest center of printing and publishing in the nation.

In addition to New York City, several other cities in the state are important centers of industry and trade. These cities include Albany, Buffalo, Rochester, and Syracuse. However, New York is not just a state of business and industry. It is also a land of fertile river valleys, forested hills, tall mountains, and sparkling lakes. New York's many scenic attractions draw millions of tourists each year. Niagara Falls, the state's most magnificent natural wonder, is a chief attraction. New York City is also a major tourist center.

New York was one of the original 13 states. Henry Hudson, an English explorer sailing under the Dutch flag, claimed the New York region for the Netherlands in 1609. The Dutch named the region New Netherland. On Manhattan Island, the Dutch established New Amster-
The Avenue of the Americas runs through the center of Manhattan in New York City, the largest city in the United States.

Interesting facts about New York

"Uncle Sam," the national symbol of the United States, originated in Troy. Samuel Wilson had a meat-packing business in Troy when the War of 1812 broke out. His company received a large contract to supply meat for United States troops. These shipments went out in barrels marked "U.S." for United States. However, the abbreviation was not yet common and people asked what it meant. They were jokingly told that U.S. stood for Uncle Sam. The nickname eventually came to personify the nation. In 1961, Congress adopted a resolution recognizing Samuel Wilson as the person who inspired the Uncle Sam symbol.

Radio City Music Hall in New York City is the world's largest indoor theater. The hall, home of the famous dancing Rockettes, has a seating capacity of 5,900.

The first escalator was manufactured by the Otis Elevator Company of New York City in 1899. It was exhibited at the Paris Exposition in 1900. In 1901, the escalator was returned to the United States and installed in a building in Philadelphia.

The World Trade Center in New York City, officially dedicated in 1973, included twin towers that were among the world's tallest skyscrapers. The towers were destroyed on Sept 11, 2001, in the worst terrorist attack in U.S. history.

The Empire State Plaza in Albany includes the State Capitol, center, and other government buildings.
New York in brief

Symbols of New York
The New York coat of arms appears on both the state flag and the state seal. On the arms, a shield displays a New York landscape with ships on a river, mountains, and a rising sun. A bald eagle perches on a globe above the shield. A figure representing Liberty stands to the left. The figure on the right symbolizes Justice. The flag was adopted in 1909, and the seal was adopted in 1882.

General information
Statehood: July 26, 1788, the 11th state.
State abbreviations: N.Y. (traditional); NY (postal).
State motto: Excelsior (Ever Upward).

Land and climate
Area: 49,112 mi² (127,200 km²), including 1,888 mi² (4,891 km²) of inland water but excluding 4,877 mi² (12,632 km²) of Great Lakes and coastal water.
Elevation: Highest—Mount Marcy, 5,344 ft (1,629 m) above sea level. Lowest—sea level along the Atlantic Ocean.
Coastline: 127 mi (204 km).
Record high temperature: 108 °F (42 °C) at Troy on July 22, 1926.
Record low temperature: −52 °F (−47 °C) at Old Forge on Feb. 18, 1979.
Average July temperature: 69 °F (21 °C).
Average January temperature: 21 °F (−6 °C).
Average yearly precipitation: 36 in (99 cm).

Important dates
1609 Henry Hudson explored the Hudson River.
1788 New York became the 11th state on July 26.
1825 The Erie Canal was opened, linking the Hudson River and the Great Lakes.

People
Population: 18,976,457 (2000 census)
Rank among the states: 3rd
Density: 386 per mi² (149 per km²), U.S. average 78 per mi² (30 per km²)
Distribution: 84 percent urban, 16 percent rural
Largest cities in New York
New York City 8,008,278
Buffalo 292,648
Rochester 219,773
Yonkers 196,086
Syracuse 147,306
Albany 95,658

Economy
Chief products
Agriculture: milk.
Manufacturing: chemicals, machinery, computer and electronic products, food products, transportation equipment, printed materials, clothing.
Mining: crushed stone, salt.

Gross state product
Value of goods and services produced in 1998: $706,884,000,000.
Services include community, business, and personal services; finance; government; trade; and transportation, communication, and utilities. Industry includes construction, manufacturing, and mining. Agriculture includes agriculture, fishing, and forestry.

Government
State government
Governor: 4-year term
State senators: 61; 2-year terms
State representatives: 150; 2-year terms
Counties: 62
Federal government
United States senators: 2
United States representatives: 31 (29)
Electoral Votes: 33 (31)

Sources of information
For information about tourism, write to: New York State Division of Tourism, P.O. Box 2603, Albany, NY 12220-0603. The Web site at www.iloveny.com also provides information.
For information on the economy, write to: New York State Department of Economic Development, 30 S. Pearl Street, Albany, NY 12245.
The state's official Web site at www.state.ny.us also provides a gateway to much information on New York's economy, government, and history.

The New York State Thruway (now the Governor Thomas E. Dewey Thruway) was completed.
New York voters approved a bond act to finance environmental projects, especially the cleaning up of hazardous waste sites.

Construction of United Nations Headquarters in New York City was completed.
The twin towers of the World Trade Center in New York City were destroyed in the worst terrorist attack in U.S. history.
Population. The 2000 United States census reported that New York had 18,976,457 people. The population of the state had increased about 51 percent over the 1990 figure, 17,990,455.

About 92 of every 100 of New York's people live within the state's metropolitan areas (see Metropolitan area). Three of the state's 13 metropolitan areas have populations of 1 million or more. These areas are Nassau-Suffolk, New York, and Rochester. For a complete list and populations of these areas, see the Index to the political map of New York.

New York City is the largest United States city in population. Its metropolitan area ranks as the country's second largest, after the Los Angeles metropolitan area. New York City and its metropolitan area are among the world's largest cities in population. The 2000 United States Census reported that New York City had 8,008,278 people, and that its metropolitan area had 9,314,235 people. Four other cities in New York with more than 100,000 people are, in order of size, Buffalo, Rochester, Yonkers, and Syracuse.

New York, especially New York City, has long had a diverse population. Here, peoples of many countries and various ethnic groups have settled and adopted a common culture, while retaining many of their own customs. About 16 of every 100 people were born in another country. One or both parents of a fifth of the American-born New Yorkers were born in other countries. The largest groups born in other lands, in order of size, came from the Dominican Republic, Italy, Jamaica, China, the former Soviet Union, Germany, Poland, and Haiti. Many Puerto Ricans have arrived since the end of World War II in 1945. About 1 million Puerto Ricans live in New York City. More than 3 million African Americans live in New York—more than in any other state.

Schools. In 1784, the New York Legislature established an agency called the University of the State of New York. This agency controls and supervises the educational system. The University of the State of New York is not a university in the usual sense of the word. A 16-member board of regents governs the university. The Legislature elects the regents to five-year terms. The regents receive no pay for serving on the board. The board has sweeping powers over all education in the state—elementary, secondary, and higher education—private and public. Its powers include setting educational standards, distributing public funds, awarding scholarships, and incorporating colleges and universities.

The powers and duties of the regents are administered by the State Education Department. The state commissioner of education heads the department. The regents appoint the commissioner for an indefinite term. In 1948, the Legislature established the State University of New York. This statewide university system has one of the largest enrollments of any university in the United States. Headquarters of the system are located in Albany.

The State Education Department, responsible to the board of regents, supervises the state's local public school districts. Each district has its own school board. Children from age 6 through 15 must attend school. For the number of students and teachers in New York, see Education (table).

Libraries. The first libraries in New York were privately owned. In 1698, 1713, and 1730, clergymen gave books to the city for a public library. However, no library was established, and the books were destroyed during the Revolutionary War in America (1775-1783). The first circulating library was the New York Society Library, founded in New York City in 1754 and still in existence.

Today, the state has hundreds of public libraries, including central city libraries and their branches. The New York Public Library located in New York City includes research libraries and a large number of branch libraries. This library system is one of the largest in the United States.

Columbia University in New York City has one of the largest collections among the state's college and university libraries. Other large college and university libraries include those at Cornell University located in Ithaca; the four centers of the State University of New York, located in Albany, Binghamton, Buffalo, and Stony Brook; and Syracuse University. The Sibley Musical Library of the University of Rochester has one of the few library buildings in the United States devoted entirely to music.

Population density
The New York City area is New York's most thickly populated region by far. The area between Albany and Buffalo is also heavily populated. Northern New York has relatively few people.

### Cornell University's main campus

Cornell University's main campus is located in Ithaca. The Urs Library and McGraw Tower, center, stand on the main quadrangle of the College of Arts and Sciences.
New York's numerous special libraries include the Grosvenor Collection in the Buffalo and Erie County Public Library, which is an outstanding reference library; the Morgan Library in New York City, which has an excellent collection of rare manuscripts and early books; and the Frick Art Reference Library, also in New York City.

The New York State Library was founded in Albany in 1818. The state library houses a comprehensive collection on New York history, including records of the early Dutch colonists.

In addition, the New York State Library holds a number of important national documents. These holdings include autographs of all the signers of the Declaration of Independence, the preliminary Emancipation Proclamation, and George Washington's farewell address.

The New York State Museum in Albany includes exhibits on New York's history. This exhibit re-creates a scene from a New York City tenement neighborhood in the early 1900's.

The National Baseball Hall of Fame and Museum is located in Cooperstown. The institution pays tribute to great players and features exhibits on the history of the game.

The Juilliard School in New York City is a leading school for the performing arts. Courses of study include music, dance, and drama.

**Museums.** The New York State Museum, founded in Albany in 1836, is one of the oldest state museums in the nation. The regents of the University of the State of New York supervise this museum. The museum’s collections deal with natural history, science, and the art and history of the state.

The Metropolitan Museum of Art in New York City is the largest art museum in the United States. The state’s other outstanding museums include the Museum of Modern Art, the American Museum of Natural History, and the Guggenheim Museum, all in New York City; and the National Baseball Hall of Fame and Museum and the Farmers’ Museum and 19th Century Village, both located in Cooperstown. The George Eastman House International Museum of Photography and Film in Rochester contains an outstanding collection of photographs.

**Cadets celebrate graduation** from the United States Military Academy in West Point. The academy’s four-year program prepares young men and women for careers as Army officers.

**The Guggenheim Museum** in New York City displays works of art in an unusual circular building designed by Frank Lloyd Wright. Solomon R. Guggenheim founded the museum in 1937 to promote modern art and education in art.

**The New York Public Library** in New York City has more volumes and more branches than any other city public library in the United States.

New York is one of the chief vacationlands in the United States. Its forested mountains, shimmering lakes, sandy beaches, and vast areas of unspoiled wilderness attract millions of summer vacationers yearly. Long Island's beaches and the Thousand Islands area are especially popular for fishing and water sports. Winter sports fans enjoy New York's excellent facilities for skiing, snowmobiling, tobogganng, iceboating, ice fishing, and ice-skating. Visitors also come to see New York's many historic forts and houses, and such magnificent wonders of nature as Niagara Falls. Every major urban center has places of historical and cultural interest. New York City's attractions draw millions of visitors a year. See New York City.

Many cultural festivals, historical celebrations, and sports competitions are held in New York every year. The New York State Fair is held annually in Syracuse in late August and early September. Buffalo, Niagara Falls, and Ogdensburg hold international festivals with the Canadian towns they border.

The Metropolitan Opera House at Lincoln Center in New York City

Thomas A. Moore, FPG

Places to visit

Following are brief descriptions of some of New York's many interesting places to visit.

Corning Glass Center, in Corning, features a factory that makes Steuben glass, a type of art glass. The center also includes a Museum of Glass, Hall of Science and Industry, and shops.

Farmers' Museum, near Cooperstown, has early agricultural tools and appliances. Nearby is the 19th Century Village. It includes a country school, law office, village store, blacksmith shop, print shop, doctor's office, church, tavern, and farmhouse and barn. All were built in the late 1700's or early 1800's.

Fort Niagara, near Youngstown, was the scene of fighting during the French and Indian War (1754-1763) and the War of 1812 (1812-1815).

Fort Ticonderoga, on Lake Champlain, is a reconstruction of the colonial fort where Ethan Allen and his Green Mountain Boys defied the British and forced them to surrender in 1775.

Home of Franklin D. Roosevelt National Historic Site, in Hyde Park, includes the president's grave and Val Kill, Eleanor Roosevelt's cottage. Nearby, the Franklin D. Roosevelt Library and Museum has many of Roosevelt's books, ship models, and other personal belongings.

Lake Placid, a village in the Adirondack Mountains, is a world-famous resort. It is noted for its glacial lake and its excellent facilities for winter and summer sports. The 1932 and 1980 Winter Olympics took place there.

Literary shrines may be seen throughout New York. They include John Burroughs's birthplace in Roxbury, Thomas Paine's home in New Rochelle, and Walt Whitman's birthplace near Huntington. Mark Twain's study and grave are in Elmira. The cottage in which Robert Louis Stevenson wrote several of his books is in Saranac Lake. The cottage in which Edgar Allan Poe wrote many poems is in the Bronx, in New York City.

National Baseball Hall of Fame and Museum, in Cooperstown, honors great baseball players and displays historic equipment of the game. A new theater seats 200 people.

Niagara Falls, in the city of Niagara Falls, is the most famous, most accessible waterfall in the world. Water plunges into a steep-walled gorge at the rate of about 100,000 cubic feet (2,800 cubic meters) a second.

Saratoga Springs is a health resort noted for its mineral springs. The Saratoga Performing Arts Center is the summer home of the New York City Ballet, the New York City Opera, and the Philadelphia Orchestra. Saratoga Springs also has harness and thoroughbred race tracks. Museums include the National Museum of Racing and the National Museum of Dance.

West Point, on the Hudson River north of New York City, is the home of the United States Military Academy.

National parklands. New York's national parklands include many sites of historical importance and a number of areas preserved for their attractive recreational features. For example, Saratoga National Historical Park, near Stillwater, includes the battlefield on which the Americans defeated a British army in 1777 during the Revolutionary War. Castle Clinton National Monument, in New York City, originally a fort, was once a landing station for immigrants. Statue of Liberty National Monument stands in Upper New York Bay at the entrance to New York Harbor. Fire Island National Seashore features the beaches, dunes, marshes, and wildlife of Fire Island, a barrier island off Long Island.

State parks and forests. New York has about 150 state parks and about 60 forest areas. Adirondack Park, covering 6 million acres (2.4 million hectares) in the Adirondacks, is the largest park in the nation. The state owns about 40 percent of the park. Watkins Glen State Park, with 18 waterfalls, is one of the scenic wonders of North America. Letchworth State Park, on the Genesee River, is famous for its scenic canyon, the Genesee Gorge. For information, write to the Office of Parks, Recreation, and Historic Preservation, Albany, NY 12238.
Annual events

January-March
Bobsled and luge competitions in Lake Placid (every weekend, January through mid-March); Ski jumping competitions in Lake Placid (early January and mid-March); Winterfest in Syracuse (mid-February); Westminster Kennel Club Dog Show in New York City (February); Winter Carnival in Saranac Lake (February); St. Patrick's Day Parade in New York City (March).

April-June
- Schoharie County Maple Festival in Jefferson (May)
- Hudson River White Water Derby in North Creek (May)
- National Lake Trout Derby on Seneca Lake near Geneva (May)
- Festival of Lilacs in Rochester (May)
- Empire State Regatta in Albany (June)
- A Festival of Gold in the Niagara region (mid-April-mid-May)
- Dressage at Saratoga in Saratoga (Memorial Day Weekend)
- Belmont Stakes Horse Race on Long Island (early June)

July-September
- Jazz Festival New York in New York City, Saratoga Springs, and Canandaigua (July)
- Annual Summer Ski Jump in Lake Placid (July)
- German Alps Festival in Hunter, near Tannersville (July)
- Friendship Festival in Buffalo (July)
- Mormon Religious Pageant at Hill Cumorah near Palmyra (mid-July)
- National Baseball Hall of Fame Induction Ceremony in Cooperstown (late July or early August)
- The Great New York State Fair in Syracuse (August)
- Central New York Scottish Games in Liverpool (August)
- United States Tennis Association Championships in Flushing Meadow, Long Island (late August and early September)
- Pulaski Salmon Festival (September)
- Adirondack Hot Air Balloon Festival in Glens Falls (September)

October-December
- Oyster Festival in Oyster Bay, Long Island (October)
- Thanksgiving Day Parade in New York City (November)
- Snowbird Soaring Regatta at Elmira (late November)
- Festival of Lights in Niagara Falls (Thanksgiving to early January)
- Rockefeller Center Tree Lighting Ceremony in New York City (December)
Land regions. In the Pleistocene Epoch, which ended about 11,500 years ago, a sheet of ice up to 2 miles (3.2 kilometers) thick in places spread across almost all the area in what is now New York. It formed many of the state’s most striking natural features by deepening valleys, rounding off mountains, and depositing sand, stones, and pebbles. Most of New York’s soils have been formed from materials deposited by the ice.

New York has eight land regions: (1) the Atlantic Coastal Plain, (2) the New England Upland, (3) the Hudson-Mohawk Lowland, (4) the Adirondack Upland, (5) the Tug Hill Plateau, (6) the St. Lawrence Lowland, (7) the Erie-Ontario Lowland, and (8) the Appalachian Plateau.

The Atlantic Coastal Plain covers Long Island and Staten Island. It forms part of the almost level coastal plain stretching along the Atlantic Ocean from Massachusetts to the southern tip of Florida. Staten Island and the western end of Long Island lie within New York City. Both islands are important residential districts.

Fishing is an important source of income on the Atlantic Coastal Plain. In addition, farmers raise vegetables, fruits, flowers, and poultry there. Long, offshore barrier islands and broad, sandy beaches contribute to Long Island’s popularity as a summer resort area.

The New England Upland, a region of hills and low mountains, extends along the lower half of New York’s eastern border. It includes the Taconic Mountains and the southern part of the Hudson River Valley. Also in the region is Manhattan Island, the heart of New York City.

In the Hudson Highlands near West Point, the Hudson River has cut a gorge 1,000 feet (300-meters) deep. The Hudson-Mohawk Lowland covers most of the Hudson River Valley and the Mohawk River Valley. The lowland is about 10 to 30 miles (16 to 48 kilometers) wide and provides the nation’s only natural navigable passage through the Appalachian Mountains. Since pioneer days, the Hudson and Mohawk river valleys have served as the most important transportation routes between the Atlantic Ocean and the Great Lakes. The fertile plains support fruit and dairy farms.

The Adirondack Upland is a roughly circular hill and mountain region about 100 miles (160 kilometers) in diameter in northeastern New York. The Adirondack Mountains are formed from hard, ancient rocks, perhaps the oldest in North America. More than 40 peaks rise over 4,000 feet (1,200 meters), with Mount Marcy, at 5,344 feet (1,629 meters), the highest peak in the state. The region is a famous recreation area with hundreds of scenic lakes, streams, waterfalls, and peaks. Its thin soils are poor for farming, and the frost-free growing season is short. There is some lumbering and some lead, garnet, titanium, and zinc mining in the region.

The Tug Hill Plateau, an isolated part of the Appalachian Plateau, is a relatively flat rocky area. It is separated from the Adirondack Upland by the Black River Valley. The plateau stands in the path of cold winter air masses that cross unfrozen Lake Ontario and pick up heat and moisture.
As a result, the plateau receives more snow—over 225 inches (572 centimeters) a year—than anywhere in the nation east of the Rocky Mountains. The harsh climate and thin soils restrict farming and settlement.

The St. Lawrence Lowland lies along the south bank of the St. Lawrence River and north of the Adirondack Upland. The region averages 18 miles (29 kilometers) in width. The land is level to rolling, with soils of widely varying fertility. The region has many dairy farms. Fruit orchards are common near Lake Champlain. Summer homes line the banks of the St. Lawrence River, particularly near the river's beautiful Thousand Islands.

The Erie-Ontario Lowland is a low plain south and east of Lake Erie and Lake Ontario. The plain is 5 miles (8 kilometers) wide along Lake Erie and broadens to 35 miles (56 kilometers) wide north of Syracuse. It has many swamps. Oval-shaped hills called drumlins rise from 50 to 200 feet (15 to 60 meters). They were formed from pebbles and other deposits of the ice sheet. A limestone and dolomite ridge stretching east-west between Lake Erie and Lake Ontario forms the ledge over which the Niagara River drops in its famous waterfall.

Fruit farming is a specialty in the lowland's unusually fertile soils. The region also has prosperous vegetable farms, greenhouses, plant nurseries, and dairy farms. The ease of reaching the Mohawk-Hudson transportation route to the east and an abundant supply of water power from falls on the Niagara and Genesee rivers spurred development in the region. These factors led to the growth of industrial, shipping, and service centers such as Buffalo, Rochester, and Syracuse.

The Appalachian Plateau, also known as the Allegheny Plateau, covers half of the state and is New York's largest land region. In the western and central portions of the plateau, broad uplands 800 to 2,000 feet (240 to 610 meters) above sea level are separated by ice-deepened valleys. At the Finger Lakes, the deepest valleys are now occupied by long, deep lakes.

In the south and east, the plateau rises. The Catskill Mountains, at 2,000 to 4,000 feet (610 to 1,200 meters) high, are a year-round recreation area. Reservoirs in the Catskills help supply New York City with water.

The rugged Appalachian Plateau supports only smaller cities, villages, and population centers except for Binghamton. Most Appalachian Plateau farms specialize in dairying. The most fertile and level lands lie to the north between the Finger Lakes, and along river valleys emptying out of the Catskills. Vineyards, nurseries, and vegetable farms can be found there.

Coastline and shoreline. New York's coastline stretches 127 miles (204 kilometers) along the Atlantic Ocean. This figure does not include the coastline along Long Island Sound. Including the shoreline of every bay and inlet on Long Island, the state's coastline is almost 1,850 miles (2,977 kilometers) long. New York City has one of the world's great natural harbors. The harbor is deep and almost completely protected by land. Excluding bays and inlets, the state has 275 miles (443 kilometers) of shoreline along Lakes Erie and Ontario, 192 miles (309 kilometers) along the Niagara and St. Lawrence rivers, and 212 miles (341 kilometers) along islands and Long Island Sound. Buffalo is New York's chief Great Lakes port. Oceangoing ships reach it through the St. Lawrence Seaway.

Mountains. The Adirondacks in northern New York are the state's highest range. Two peaks rise over 5,000 feet (1,500 meters). They are 5,344-foot (1,629-meter) Mount Marcy, and 5,112-foot (1,558-meter) Algonquin Peak (also known as Mount MacIntyre). At 4,204 feet (1,281 meters), Slide Mountain is the tallest peak in the Catskills. South of the Catskills, and extending into New Jersey, a 1,000- to 2,000-foot (300- to 600-meter) ridge known as the Shawangunk Mountains is famed among rock climbers. The Helderberg Escarpment presents a steep 1,000-foot (300-meter) cliff facing Albany to the northeast. The Taconic Mountains, which rise to 2,000 feet (610 meters) east of the Hudson, are a western extension of the Berkshire Mountains in Massachusetts.

Rivers. New York's most important rivers, the Hudson and the Mohawk, form one of the nation's great trade routes. The Hudson originates from a lake called Tear-of-the-Clouds high on Mount Marcy. It tumbles south through narrow gorges with many rapids and waterfalls. Oceangoing ships can sail from New York City 150 miles (241 kilometers) up the Hudson as far north as Albany. A Cohoes, about midway on the Hudson's 306-mile (492-kilometer) trip to the sea, the Mohawk enters.

The Mohawk River, the chief branch of the Hudson River, connects the Hudson with the Erie-Ontario Lowland. The Mohawk rises in Oneida County and flows southeastward for about 145 miles (233 kilometers). It drains central New York. The Mohawk was important in the development of the interior because the river and its tributaries provided water for the eastern half of the Erie Canal.

The Genesee River starts in Pennsylvania, flows north through western New York, and empties into Lake Ontario north of Rochester. At Letchworth State Park, it passes through a spectacular gorge 600 feet (180 meters) deep nicknamed "The Grand Canyon of the East." The Oswego River and its branch, the Seneca, also empty into Lake Ontario. The Delaware, an important sports fishing and canoeing river, tumbles out of the Catskills to form the eastern boundary between New York and Pennsylvania. The Susquehanna River originates from Otsego Lake and flows southwest past Binghamton before entering Pennsylvania.

Other rivers include the short but powerful Niagara, flowing 34 miles (55 kilometers) from Lake Erie to Lake Ontario, and the St. Lawrence. Both carry huge quantities of water and form part of the international boundary with Canada. The East River is actually a strait that connects Long Island Sound with New York Bay and separates Manhattan Island from Long Island.

Waterfalls. The state's most famous waterfall, Niagara Falls, is also New York's most important source of hydroelectric power. The American Falls, at 176 feet (54 meters), lie in New York. The St. Lawrence rapids near Massena have also been developed as a major source of power. The thin, delicate Taughannock Falls is the highest waterfall in the northeastern part of the nation. It drops 215 feet (66 meters) into a spectacular glen before entering Lake Cayuga in the Finger Lakes region.

Lakes. Most of New York's several thousand lakes lie in the Adirondack region. About 2,000 lakes and ponds are nestled among the hills and mountains there. Many of the larger Adirondack lakes support year-round resorts.

Lake George, on the eastern edge of the Adirond-
New York, a popular vacation spot. It empties into Lake Champlain. Lake Champlain lies on the New York-Vermont border and extends into the Canadian province of Quebec.

New York's largest lakes, by far, are Lake Erie and Lake Ontario. They form part of the boundary between the United States and Canada.

The long and narrow Finger Lakes lie parallel to one another in the Appalachian Plateau. Lakes Cayuga and Seneca are the largest and deepest of the 11 Finger Lakes. Lake Oneida, northeast of Syracuse, has the largest surface area lying entirely within the state. Covering 30 square miles (210 square kilometers), the lake is noted for its excellent boating and fishing. Chautauqua Lake in southwestern New York is a favorite summer resort. A famous arts and education center, the Chautauqua Institute, lies on its bank.

**Plant and animal life.** New York has many kinds of trees and plants. Forests cover about half the state, with the greatest ones in the Adirondacks. Smaller forests thrive throughout the Appalachian regions, where large areas of abandoned farmland have once again become woodland. About 150 types of trees, of which about 135 are native, grow in New York. Trees of commercial importance include balsam fir, beech, black cherry, oak, pine, spruce, sugar maple, and yellow birch. Apple orchards are common in the Lake Ontario Lowland, along Lake Champlain, and in the Hudson River Valley.

Many wild flowers bloom along river valleys throughout New York. They include black-eyed Susans, devil's paintbrush, and Queen Anne's lace. Buttercups, goldenrod, violets, and wild roses grow along the borders of forests and in clearings. White and yellow water lilies thrive in many Adirondack lakes. Other wild flowers common in New York include bunchberry, chanterelle's nightshade, goldenthread, Indian pipe, starflower, and trillium.

Some animals that once were common in New York are now endangered or extinct. These include such fur-bearing animals as marten, mink, and otters, and such

**Average yearly precipitation**
Precipitation in the state varies considerably. The wettest areas generally are in the mountains and in the southeast.

### Average January Temperatures
The northeastern part of New York has the lowest temperatures. The west and southeast have the mildest winters.

### Average July Temperatures
The state has fairly even summertime temperatures. The southeast and northwest are generally the warmest sections.
important predators as the mountain lion, timber wolf, and wolverine. However, other native animals have adapted to human settlement. Porcupines, rabbits, red fox, squirrels, and woodchucks abound in some areas. Many deer roam the forests. The state’s fur-bearing animals include beavers, muskrats, opossums, raccoons, and skunks. Eastern black bears and wildcats are found in remote mountain areas.

Game birds include Canada geese, grouse, partridges, pheasants, quail, wild ducks, and wild turkeys. Falcons, hawks, and owls can also be found. Bald and golden eagles are seen in New York occasionally.

Freshwater fish common in New York include bass, perch, pike, salmon, sunfish, and trout. Bluefish, clams, flounder, oysters, shad, swordfish, and many other fish and shellfish live in bays and ocean waters.

Climate. New York's climate varies greatly. The average January temperature ranges from 14 °F (−10 °C) in the central Adirondacks to 30 °F (−1 °C) on Long Island.

The average July temperature in the central Adirondacks is 66 °F (19 °C), and 74 °F (23 °C) on Long Island. New York's record high temperature, 108 °F (42 °C), was recorded at Troy in east-central New York on July 22, 1926. Old Forge, in the Fulton Chain Lakes area, recorded a record low of −52 °F (−47 °C) on Feb. 18, 1979.

The frost-free growing season in New York ranges from an average high of 200 days on Long Island to less than 100 days in the central Adirondacks. New York’s average annual precipitation (rain, melted snow, and other forms of moisture) ranges from 32 to 38 inches (81 to 147 centimeters). The most precipitation occurs on Tug Hill, the southwestern slopes of the Adirondacks, the central Catskills, and Long Island. In central, northern, and western New York, the Great Lakes, with their broad expanse of open water, supply moisture for many cloudy days and abundant winter snowfall. Syracuse, Rochester, and Buffalo routinely receive a greater annual snowfall than any other large city in the nation.

Economy

New York has a varied economy. Its excellent location, large population, and outstanding transportation facilities have helped make it a leader in business and industry. New York ranks near the top among all states in many important economic sectors, including accounting, banking, corporation management, manufacturing, public relations, publishing, and trade.

Service industries, taken together, account for the largest portion of New York's gross state product—the total value of goods and services produced in the state annually. Only California has a higher gross state product than New York. Finance, insurance, and real estate form the single most important economic activity in New York.

Much of the state's economic production takes place in New York City. The city is one of the world's leading economic centers. But other parts of the state also contribute to the economy. For example, northern New York is one of the nation's leading dairy-farming regions, and Rochester is among the most important U.S. manufacturing areas.

Natural resources in New York include fertile soils, a variety of minerals, and abundant supplies of water.

Lake Placid, a beautiful glacial lake, lies in the Adirondack Mountains of northeastern New York. The village of Lake Placid is a popular summer and winter resort.

*GSP = gross state product, the total value of goods and services produced in a year less than one half of 1 percent.
Figures are for 1998.
Soils. The ice sheet that once covered what is now New York left behind a variety of soils. The Atlantic Coastal Plain has fertile sandy and alluvial (water-deposited) soils. The Erie-Ontario Lowland, the Hudson-Mohawk Lowland, the St. Lawrence Lowland, and river valleys throughout the Appalachian Plateau have fertile, well-drained soils. The soils of the rest of the Appalachian Plateau and the New England Upland tend to be poor, gray-brown, silty soils. These soils developed from glacial drift. Drift is material ranging in size from great boulders to fine rock dust laid down by the melting ice sheet. The Catskills, the Adirondack Upland, and Tug Hill Plateau have rough, stony soils.

Minerals. The Adirondacks and St. Lawrence Lowland are important suppliers of lead, talc, and zinc. The Adirondacks also supply a major part of the country’s industrial garnets, used for watch jewels and in the manufacture of such abrasives as sandpaper. Petroleum and natural gas lie in western New York.

Clay, which is used in brick and cement manufacturing, is found in the Hudson Valley and in Erie and Onondaga counties. Deposits of sand, gravel, and stone, all of which are used in construction, are found throughout the state. Granite, limestone, and sandstone are especially valuable. Major salt and gypsum deposits are found in central and western parts of New York.

Water. New York has plentiful supplies of water for use by homes, factories, and farms. Falls and rapids on the Niagara and St. Lawrence rivers are among the largest sources of hydroelectric power in North America. In addition, New York’s rivers are also used for recreation and transportation.

Service industries account for the largest part of New York’s gross state product. Most of the service industries are concentrated in the state’s metropolitan areas, but especially in the New York City area.

Finance, insurance, and real estate form New York’s most important service industry in terms of the gross state product. New York City is the nation’s leading financial center. The city is the home of most of the largest U.S. banks, including Chase Manhattan. Other large financial companies headquartered in the city include American Express, Citigroup, Merrill Lynch, and Morgan Stanley Dean Witter. The New York Stock Exchange is the nation’s largest securities exchange. Many major insurance companies are based in New York City. The real estate business is also a major economic activity in New York City. A high demand for prime office space in Manhattan has resulted in some of the world’s highest property values. Other important financial centers in the state include Albany, Buffalo, and Rochester.

Community, business, and personal services rank second among New York’s service industries. This industry employs more of the state’s workers than any other economic activity. Community, business, and personal services include activities such as private health care, accounting firms, management consulting firms, law firms, advertising agencies, entertainment companies, and personnel agencies. Private health care, the largest part of the industry, is important throughout the state. Several of the world’s largest law firms and advertising agencies are based in Manhattan. Movies, plays, and sporting events are among the leading forms of entertainment in New York.

Wholesale and retail trade is the third-ranking service industry in New York. The wholesale trade of clothing, grain, groceries, jewelry, and petroleum is important in the state. Many wholesale companies are based in New York City. The city’s port handles much foreign trade. A large number of wholesale companies are also based in Albany and Buffalo and on Long Island. Major types of retail firms in the state include car dealerships, food stores, and restaurants. Leading retail companies based in New York include R. H. Macy and Melville.

Government ranks fourth among the state’s service industries. Government services include the operation of public schools and hospitals, and military establishments. Many of New York’s people are employed by local school districts and by the state higher education system. State government offices are based in Albany. New York City has many federal, state, and local government workers.

Transportation, communication, and utilities rank fifth among service industries in New York. The state's
largest utility companies are Consolidated Edison and Niagara Mohawk Power Corporation. Two of the largest U.S. communication companies, AT&T Corp. and Verizon Communications, are headquartered in New York City. More information about transportation and communication appears later in this section.

Manufacturing. Goods produced in New York have a value added by manufacture of about $80 billion yearly. Value added by manufacture is the increase in value of raw materials after they become finished products.

New York ranks among the leading manufacturing states. The state has about 24,000 industrial plants. These plants employ nearly 800,000 workers. New York's factories make a wide variety of products—from huge machines to tiny computer chips.

Chemicals rank first among New York's manufactured products. Pharmaceuticals and chemicals used in the making of photographic film and paper are the state's leading chemical products. Bristol-Myers Squibb, a top maker of pharmaceuticals, is headquartered in New York City. Eastman Kodak, a leading maker of photographic chemicals and many other products, is based in Rochester. Other important chemical products made in the state include soaps, industrial chemicals, paints, plastics, and agricultural chemicals.

Machinery is the state's second-ranking manufactured product in terms of value added. The industry's leading products include industrial equipment, photographic and photocopying equipment, and refrigeration equipment. The major centers of machinery production in the state include Buffalo, New York City, Poughkeepsie, Rochester, and Syracuse.

Computer and electronic products rank third among New York's manufactures. Leading products in this category include computer components and microchips, communications equipment, and surveillance and navigation equipment. The chief centers of the electronic products industry are Binghamton, Buffalo, New York City, Rochester, the Nassau-Suffolk metropolitan area, Schenectady, and Utica. International Business Machines (IBM), a major computer manufacturer, has its headquarters just north of New York City.

Food products rank fourth among the state's manufactured goods. The state's important food products include dairy products, canned fruits and vegetables, flour, baked goods, beer, and soft drinks. The state's major centers of food production include the Buffalo-Niagara Falls area, Nassau and Suffolk counties on Long Island, New York City, and Rochester.

Transportation equipment is New York's fifth-ranking manufactured product. Motor vehicle parts and aerospace equipment are the most valuable transportation products made in the state.

Other manufacturing industries produce clothing, fabricated metal products, printed materials, and many other items. New York City ranks as the nation's chief center for the production of women's clothing and makes large amounts of men's clothing. Rome is a center for the manufacture of copper products. New York leads all other states by far in printing and publishing. New York City is the center of the publishing industry in the United States. The New York City area does about 10 percent of the nation's printing and publishing. Other important products manufactured in the state include paper products, plastics and rubber products, medical supplies, and jewelry.

Agriculture. Farmland covers a fourth of New York's land area. The state has approximately 38,000 farms.

Livestock and livestock products provide about two-thirds of New York's agricultural income. Milk is the state's leading agricultural product. New York ranks among the leading states in milk production. The northern and central parts of the state are the leading areas for milk production.

Beef cattle are an important source of livestock income in New York. Dairy herds are also a significant source of beef. Milk cows that are no longer productive are often sold to slaughterhouses.

New York farmers also raise poultry and eggs, hogs, and sheep. Sullivan County in the Catskills and Suffolk County on Long Island lead in egg and poultry production. Egg farms provide much income in Sullivan County. Western New York is the leading area for raising hogs and sheep.

Crops provide about a third of New York's agricultural income. The state's leading field crops are hay and corn, which are used primarily as feed for the state's dairy cattle. The Erie-Ontario Lowland in western New York is the leading region for hay and corn production.

New York is a leading center of fruit and vegetable production in the eastern United States. Orange and Suffolk counties, both of which lie near New York City, have many small vegetable farms, also called truck farms. Western New York also produces large amounts of vegetables. The most important vegetables grown in the state include cabbages, cucumbers, green peas, onions, snap beans, sweet corn, and tomatoes.

Apples are the leading fruit crop in New York, and grapes rank second. New York ranks among the leading states in the production of apples. The state's largest apple orchards lie near Lake Ontario and the Hudson River. Chautauqua County in far west New York leads in grape production. Cherries and peaches are also important fruit crops grown in the state.

Greenhouse and nursery products are an important source of agricultural income in New York. Flowers are the most important type of greenhouse and nursery product in the state. Suffolk County on Long Island accounts for about half of the income from greenhouse and nursery products. Other New York farm products include maple syrup, oats, potatoes, and wheat.

Mining. New York's leading mined products include stone, salt, and sand and gravel. Limestone is the most important type of stone quarried in the state. Most of the stone is crushed and used for road construction. Some is used to make Portland cement, a mixture of burned lime and clay. Most salt-mining operations are in the Appalachian Plateau region of western New York. Sand and gravel are mined throughout the state. New York is the only state that produces wollastonite, and it ranks among the leading states in the production of garnet and zinc. The state also produces clays, lead, natural gas, peat, silver, and talc.

Fishing industry. New York has an annual fish catch valued at about $78 million. Commercial fishing takes place in Long Island waters and in Lake Erie and Lake Ontario. Clams, flounder, lobsters, oysters, scallops,
Economy of New York

This map shows the economic uses of land in New York and where the state's leading farm and mineral products are produced. Major manufacturing centers are shown in red.

scup, striped bass, and whiting are taken from Long Island Sound. Bullheads, eels, walleye, and yellow perch are caught in Lake Erie and Lake Ontario.

Electric power. Nuclear plants and hydroelectric plants each supply about 25 percent of New York's electric power. Coal-burning plants and plants that burn natural gas each supply about 20 percent. Petroleum-burning plants supply most of the rest. New York's two largest hydroelectric power projects are the St. Lawrence Power Project and the Niagara Power Project. They were developed jointly with Canada. New York imports power from Canada and exports power to Pennsylvania, New Jersey, and the New England States.

Transportation. New York lies in the heart of the most thickly populated part of the United States. It is the chief gateway to the United States from other countries. It has one of the finest natural harbors in the world and an excellent system of inland waterways. All these factors have helped New York become one of the nation's leaders in transportation.

Railroads. About 40 railroads provide freight service, and Amtrak passenger trains serve about 25 New York cities. The state's first railroad, the Mohawk and Hudson, began running between Albany and Schenectady in 1831. New York City's subway, the busiest in the nation, covers approximately 235 miles (380 kilometers). More than 4 million riders jam these trains every working day.

Aviation. John F. Kennedy International Airport and La Guardia Airport are both in the Queens borough of New York City. Kennedy Airport handles more international flights than any other airport in the United States. La Guardia Airport handles mostly domestic flights. People traveling to and from New York City also use the airport in nearby Newark, New Jersey, Albany, Buffalo, Rochester, and Syracuse also have busy airports.

Roads and highways. New York has about 112,000 miles (180,000 kilometers) of roads and highways. The Governor Thomas E. Dewey Thruway is the world's longest toll superhighway. This 640-mile (1,030-kilometer) expressway runs across the state between New York City and the border with Pennsylvania at the western end of the state. It links Albany, Utica, Syracuse, Rochester, and Buffalo. Interstate 88 links Binghamton and Albany. Interstate 81 runs between the New York-Pennsylvania border south of Binghamton and the Canadian border, and Interstate 87 links Albany with the Canadian border.

New York has many great bridges. The George Washington, Tappan Zee, Bear Mountain, Mid-Hudson, Newburgh-Beacon, and Rip Van Winkle bridges span the Hudson River. The Brooklyn and Triborough bridges cross the East River. The Peace Bridge links Buffalo with Fort Erie in Canada. The Verrazano-Narrows Bridge across the Narrows Channel connects Brooklyn and Staten Island. Its 4,260-foot (1,298-meter) center span is the nation's longest. The Thousand Islands International Bridge connects the state with Canada.

Waterways. New York has one of the nation's largest inland waterway systems—the New York State Canal System. The system was completed in 1918, and includes parts of the old Erie Canal and several other waterways. The Erie Canal, which was opened in 1825, connected the Hudson River with Lake Erie. It played an important part in the economic growth of New York and the entire United States. The New York State Canal System and its connecting waterways cover about 800 miles (1,300 kilometers). They extend from Lake Champlain and the Hudson River to Lake Erie and Lake Ontario. The St. Lawrence Seaway, which was opened in 1959, turned New York's Great Lakes ports into seaports.

Shipping. New York City's port, officially called the Port of New York and New Jersey, is one of the world's
busiest seaports. Huge ocean liners and freighters from all parts of the world dock at this great port. Other major New York ports include Albany, Buffalo, Hempstead Harbor, and Port Jefferson, with more limited shipping from Chester and Tarrytown. Albany is a major shipping center, though it lies about 150 miles (240 kilometers) from the Atlantic Ocean. The Hudson River has been deepened so that ocean ships can reach Albany.

**Communication.** New York leads the nation in producing books, magazines, and newspapers. William Bradford established New York's first newspaper, the *New-York Gazette*, in New York City in 1725. Today, New York has about 830 newspapers, about 75 of which are dailies. One of the world's most influential newspapers, *The New York Times*, is published in New York City. Other well-known New York City newspapers are the *New York Post*, which is one of the nation's oldest papers, and the *Daily News*. *The Wall Street Journal*, the nation's leading business and financial newspaper, is also published in New York City. The Associated Press also has its headquarters there. New York publishers produce about 2,300 periodicals. *Newsweek, Reader's Digest, Sports Illustrated, Time, TV Guide*, and many other magazines all have headquarters in New York City.

WNBT, the nation's first commercial television station, began operating in New York City in 1941. New York City is the corporate headquarters of ABC Inc., CBS Inc., and NBC. The Fox Broadcasting Company originates many of its programs from New York City. The state has about 50 television stations. Cable TV systems and Internet providers serve many communities.

**Government**

**Constitution.** New York adopted its first constitution in 1777. The present Constitution was adopted in 1894, and has been amended more than 180 times. An amendment may be proposed in the State Legislature. In order to pass, the proposal must be approved by a majority in both legislative houses of two successive, separately elected legislatures. The proposed amendment must then be approved by a majority of the persons who vote on the proposal.

The Constitution may also be amended by a constitutional convention. A proposal to call a convention must be approved by a majority of the Legislature and by a majority of the voters. Constitutional amendments that are suggested by the convention become law after they have been approved by a majority of the citizens voting on them.

**Executive.** The governor of New York is elected to a four-year term and may serve an unlimited number of terms. The lieutenant governor, attorney general, and comptroller are also elected to four-year terms. The secretary of state is appointed by the governor with the approval of the state Senate. The governor heads the executive department, one of the 20 departments that administer the state government. The governor, with the approval of the Senate, appoints most other department heads.

**Legislature** of New York consists of a Senate of 61 members and an Assembly of 150 members. Voters in senatorial and Assembly districts elect the members of both houses of the Legislature to two-year terms. The Legislature meets every year on the first Wednesday after the first Monday in January. Special sessions can be called by the governor or by petition of two-thirds of the Legislature. Regular and special sessions have no time limit.

**Courts.** New York is divided into 12 judicial districts. The voters in each district elect a varying number of Supreme Court judges to 14-year terms. Altogether, New York has about 314 Supreme Court justices. They make up the state Supreme Court.

New York is also divided into four judicial departments. Each department has an appellate division of the Supreme Court. The appellate divisions hear appeals from the Supreme Court and from other trial courts within their jurisdictions. The governor selects the Supreme Court justices of the appellate divisions. Two appellate divisions have at least seven justices each. The other two appellate divisions have five each.

The highest court in New York is the Court of Appeals. It has a chief judge and six associate judges. Each of these judges is appointed to a 14-year term. This court hears cases only from the appellate divisions of the Supreme Court.

Each New York county, except those that make up New York City, has a county court. County courts hear civil and criminal cases. A surrogate court in each county deals with wills and estates. All counties have family courts that handle domestic matters. New York City has a civil court and a criminal court. In addition, there are

*The New York State Legislature* consists of an Assembly of 150 members and a Senate of 61 members. The Assembly meets in chambers in the State Capitol in Albany, shown here.

many town justices, city court judges, and village courts in the state.

Local government. New York has 62 counties, including the 5 that make up the boroughs of New York City. A board of supervisors or a county legislature governs each county except the New York City boroughs. The officials of these boards and legislatures are elected either from the towns and cities of the county, or from county legislative districts. The major responsibilities of most counties include the administration of courts, highways, and welfare. In addition to these responsibilities, counties deal with the administration of community colleges, libraries, garbage disposal, and parks and recreation.

Within New York's counties are villages, towns, and cities. An elected mayor and board of trustees govern each village. Each town is governed by an elected supervisor and town board.

Most New York cities have the mayor-council form of government. Some cities have the city manager form of government. The state legislature has the authority to draw up city charters. Cities, in turn, may adopt and amend local laws and revise their charters, thus determining their own form of government. But New York City, because of its large population and area, has a different government from that of the other cities (see New York City [Government]).

Revenue. Taxes account for about three-fifths of the state government's general revenue (income). Federal grants and other U.S. government programs make up most of the rest. A personal income tax provides the greatest portion of the tax revenue. Other tax revenue sources include a general sales tax and taxes on corpo-rate income, public utilities, tobacco products, insurance, motor-vehicle licenses, motor fuels, and alcoholic beverages. A state lottery and charges for government services, such as toll-road collections, also contribute to the state's general revenue.

Politics. Enrolled Democratic voters in New York City usually outnumber Republicans about 5 to 1. But in the rest of the state, there are slightly more enrolled Republicans than Democrats. Albany and Erie Counties are often the only upstate counties to vote Democratic. Therefore, the two parties are fairly evenly matched, because New York City has about 40 percent of the state's total population. Republicans have generally controlled the state senate, while Democrats have controlled the assembly.

New York has 33 electoral votes—more than any other state except California. For this reason, New York plays a key role in United States presidential elections and its governors have always been considered possible presidential candidates. New York governors often have introduced national issues into state politics. Four men served as governor of New York before becoming president—Martin Van Buren, Grover Cleveland, Theodore Roosevelt, and Franklin D. Roosevelt. Five other governors—Horatio Seymour, Samuel J. Tilden, Charles Evans Hughes, Alfred E. Smith, and Thomas E. Dewey—were unsuccessful nominees for the presidency of the United States.

Since 1880, New Yorkers have voted for the winning presidential candidate in every election except those that occurred in 1916, 1948, 1968, 1988, and 2000. For New York's electoral votes and voting record, see Electoral College (table).
Early days. Two of the largest and most powerful Indian groups in North America lived in the New York region before European settlers came. One Indian group consisted of the Delaware, Mahican, Montauk, Munsee, and Wappinger tribes. These tribes made up the Algonquin family of Indians. The other Indian group was the Iroquois, or Five Nations. The Cayuga, Mohawk, Oneida, Onondaga, and Seneca tribes made up the Five Nations of the Iroquois Confederacy (see Iroquois Indians). Both Indian groups farmed, hunted, and fished. The Iroquois were especially advanced in political and social organization.

Exploration and settlement. Giovanni da Verrazzano, an Italian navigator and explorer, was probably the first European to visit the New York region. Verrazzano supposedly was hired by King Francis I of France to explore the northern part of America. Historians believe Verrazzano may have sailed into New York Bay and reached the Hudson River about 1524.

In 1609, Henry Hudson, an Englishman employed by the Dutch, sailed up the river that now bears his name. He was looking for a Northwest Passage to the Orient. Hudson's voyage gave the Netherlands a claim to the territory covering much of present-day New York, New Jersey, Delaware, and part of Connecticut. The territory was later named New Netherland.

Also in 1609, the French explorer Samuel de Champlain entered the northern part of New York from Quebec. His visit gave France a claim to the land.

The Dutch established several trading posts and prosperous settlements in the Hudson River Valley soon after Hudson's visit. There, they built up a profitable fur trade with the Indians. In 1621, a group of Dutch merchants formed the Dutch West India Company. The government of the Netherlands gave the company all rights to trade in New Netherland for the next 24 years. In 1624, the company sent about 30 families to settle in the region. Some of these families founded Fort Orange (now Albany), the first permanent white settlement in the colony. The rest of them established settlements in other parts of New Netherland.

In 1625, a group of Dutch colonists began building a fort and laying out a town on Manhattan Island. They named their settlement New Amsterdam. In 1626, Peter Minuit, the Dutch governor (or director-general), bought Manhattan from the Indians for goods worth 60 Dutch guilders, or about $24. During the next few years, Willem (now Kingston), Rensselaerswyck (now Rensselaer), Breuckelen (now Brooklyn), Schenectady, and other settlements were established in New Netherland by Dutch colonists.

In 1629, the Dutch West India Company set up the patroon (landowner) system to speed the settlement of New Netherland. Members of the company were given huge tracts of land, which they could keep if they colonized the land with settlers. Only one patroonship lasted into the 1700's, that of Kiliaen Van Rensselaer, an Amsterdam diamond merchant. His land covered much of present-day Albany, Columbia, and Rensselaer counties. Van Rensselaer began the practice of leasing his land to tenant farmers. The tenant system in New York lasted until the 1840's. A series of tenant revolts forced it to end. See Patroon system.

Under English rule. Many English colonists from Connecticut and Massachusetts settled on Long Island. For a long time, they cooperated with the Dutch. But gradually the English began to oppose the Dutch. In addition, King Charles II of England decided to take over New Netherland. He gave his brother James, the Duke of York, a charter for the territory. In 1664, the English sent a fleet to seize New Netherland. The warships dropped anchor in the harbor of New Amsterdam. Peter Stuyvesant, the Dutch governor, surrendered the settlement without a fight.

[Picture of a drawing of New Amsterdam in 1660 by Jacques Cortelyou, Museum of the City of New York]
The English renamed the territory New York, after the Duke of York, who later became King James II of England. Under the Treaty of Breda, signed in 1667, the Dutch formally gave up all New Netherland to England.

Soon after the English won control of southern New York, the French began to take great interest in the northern part. In 1669, the French explorer René-Robert Cavelier, Sieur de La Salle, entered the Niagara region. In 1731, the French built a fortress at Crown Point on Lake Champlain. They prepared to take permanent possession of northern New York. Meanwhile, in 1689, war had broken out in Europe between England and France. New York soon became a battleground in the struggle between the two countries.

From 1689 until 1763, the region suffered severely through four wars, known in America as the French and Indian wars. Battles were fought at Crown Point, Fort Niagara, Fort Ticonderoga, and many other places. The French received aid from the Algonquian Indians in the wars, but the Iroquois Indians provided assistance to the British.

The French and Indian wars delayed settlement of the frontier regions and slowed the growth of sections that had already been settled. Britain and France signed a peace treaty—the Treaty of Paris—in 1763. However, the wars cost France almost all its possessions in North America. See French and Indian wars.

In 1735, John Peter Zenger, publisher of the New-York Weekly Journal, won a great victory for freedom of the press. Zenger had criticized the British governor, and was charged with seditious libel—that is, with making statements aimed at stirring up discontent or rebellion against the government. In a historic trial, the jury found Zenger innocent.

The Revolutionary War. British policies angered many people of New York. They did not like the presence of British troops, the authority of royal judges, or taxes passed by the British Parliament. Other New Yorkers, called Loyalists or Tories, did not oppose the British. Nobody knows how many New Yorkers were Loyalists. But during and after the Revolutionary War (1775-1783), perhaps as many as 30,000 people left the state.

During the Revolutionary War, New York was the scene of many battles. The British occupied New York City during the entire war. The Loyalists helped the British and persuaded the Iroquois Indians to fight the patriots. American patriots won the First and Second Battles of Freeman's Farm in New York in 1777. These victories led to a British surrender at Saratoga and marked a turning point in the war.

Statehood. On July 9, 1776, the provincial congress of New York met in White Plains. It approved the Declaration of Independence, which the Continental Congress had adopted on July 4. The congress also organized an independent government. The next year, New York adopted its first constitution. George Clinton was elected governor. Clinton later served as vice president under two U.S. presidents, Thomas Jefferson and James Madison.

On Feb. 6, 1778, New York approved the Articles of Confederation. It did not want a strong federal government. But it finally ratified the United States Constitution on July 26, 1788. New York was the 11th state to enter the Union. New York City served as the U.S. capital from 1785 to 1790. In 1789, George Washington was inaugurated as the nation's first president. The inauguration took place in Federal Hall in New York City.

Settlement of the interior progressed rapidly. In 1779, during the Revolutionary War, General Washington sent an expedition to crush the mighty Iroquois. Troops commanded by General James Clinton raided Indian villages up through the Mohawk Valley. The soldiers then moved down the Susquehanna River to Tioga, Pennsylvania. There, they joined troops commanded by General John Sullivan. The combined force of about 3,500 men marched through the Finger Lakes region to the Genesee Valley. The soldiers destroyed Indian villages, killed the Indians' livestock, and burned their fields. The heart of the Iroquois territory was left in ruin. The military
The power of the Iroquois lay broken forever, leaving the area open to white settlement. After the Revolutionary War, soldiers who had fought in the area told of its level, fertile land. Many veterans settled on grants of land they received there. By 1810, New York had a population of 959,049, more people than any other state.

War broke out between the United States and Britain in 1812 (see War of 1812). Much of the fighting took place in frontier regions near the New York-Canada border. After the war, pioneers began to settle in the northern and western sections of the state. Many of these settlers came from other parts of New York, but many also came from Canada, New Jersey, Delaware, Pennsylvania, and especially New England. By 1820, about 500,000 people lived in frontier settlements, and the state had a population of over 1,370,000.

Growing prosperity. As the frontier was opened, the people of New York realized that better transportation would be needed between the coast and the interior. Governor De Witt Clinton had long urged the construction of a canal to link the Atlantic Ocean and the Great Lakes. In 1825, the famous Erie Canal was completed. It crossed New York from Buffalo on Lake Erie to Troy and Albany on the Hudson River. The canal provided an important link in an all-water route between New York City and Buffalo. It greatly lowered the cost of transporting goods. Farmers in the West shipped their produce to the East by way of the Great Lakes and the Erie Canal. Products from New York’s growing factories were, in turn, shipped on the canal to western markets.

The development of railroads across the state soon followed the opening of the Erie Canal. The canal and railroads greatly encouraged the state’s growing prosperity. They also provided jobs for many of the thousands of European immigrants who were pouring into the state. By 1850, New York was firmly established as the Empire State. It led the nation in population, in manufacturing, and in commerce.

European immigrants came to the United States in great numbers during the 1840s and 1850s. Many of those immigrants landed at New York Harbor, shown here.
Manhattan was purchased in 1626 by Peter Minuit, the director-general of New Netherland. He paid the Manhattan Indians about $24 in goods for the island.

John Peter Zenger, publisher of the New-York Weekly Journal, was found innocent of libel in a 1735 trial. The decision was a great victory for freedom of the press.

George Washington took the oath of office as the nation’s first president in New York City in 1789. New York City was the U.S. capital from 1785 to 1790.

The United Nations selected New York City as its permanent home in 1946. UN headquarters were completed in 1952.

President William McKinley was assassinated at the Pan American Exposition in Buffalo in 1901.

Important dates in New York

1609 Henry Hudson explored the Hudson River. Samuel de Champlain visited the New York region.
1624 The Dutch established Fort Orange (Albany), the first permanent white settlement in the New York region.
1625 Dutch settlers began building New Amsterdam (New York City).
1664 The Dutch surrendered New Amsterdam to England.
1735 Publisher John Peter Zenger was found innocent of libel, an important victory for freedom of the press.
1776 New York approved the Declaration of Independence.
1779 Military expeditions under Generals James Clinton and John Sullivan opened Iroquois land to white settlement.
1788 New York became the 11th state on July 26.
1789 George Washington was inaugurated in New York City as the first president of the United States.
1825 The Erie Canal was opened.
1831 New York's first railroad, the Mohawk and Hudson, began running between Albany and Schenectady.
1863 Mobs rioted in New York City in opposition to drafting men into the Union Army.
1901 President William McKinley was assassinated at the Pan American Exposition in Buffalo.
1939-1940 New York held a World’s Fair.
1948 New York established its first state university—the State University of New York.
1952 United Nations Headquarters was completed in New York City.
1959 The St. Lawrence Seaway opening made "ocean" ports of New York’s ports on Lake Erie and Lake Ontario.
1960 The New York State Thruway (now the Governor Thomas E. Dewey Thruway) was completed.
1967 The state legislature established a lottery with profits going to education.
1986 The voters approved a bond act to finance environmental projects, especially the cleaning up of hazardous waste sites.
2001 The twin 110-story towers of the World Trade Center in New York City were destroyed in the worst terrorist attack in United States history.
Wealthy merchants and great landowners had controlled New York since colonial days. During the early 1800's, the state adopted more and more democratic practices. In the 1820's, white men no longer had to own property to be able to vote. A new constitution adopted in 1846 required that all major state officials be elected by the voters.

In 1839, the antirent movement began when tenant farmers refused to pay rent to wealthy landowners. The antirenters, disguised as Indians, ranged the Hudson and Mohawk river valleys and fought attempts by the landlords to evict them from their farms. The antirent movement grew rapidly and became a powerful political force in New York. During the 1840's, the great landlords began the process of breaking up their estates into small independent farms. See Antirenters.

Long before the Civil War began in 1861, many of New York's people strongly opposed slavery. But some did not. In July 1863, mobs rioted for four days in New York City. They objected to drafting men into the Union Army. The mobs burned, robbed, and murdered recklessly. They killed or wounded about 500 people and destroyed more than $1 1/2 million worth of property. Troops called from the battlefield finally ended the riots. Despite the draft riots, New York provided more soldiers, supplies, and money to the Union war effort than any other state.

After the Civil War ended in 1865, new manufacturing centers grew up in various parts of New York. More and more products of the Middle West flowed through Buffalo, the state's western gateway. Increased commerce between the United States and other countries passed through New York City, the state's eastern gateway. New York City, already the nation's industrial and financial capital, also became a leading cultural center. As manufacturing continued to increase, new waves of immigrants poured in, drawn by employment opportunities. They came from Italy, Poland, Russia, and other southern and eastern European countries. By 1900, the state had more than 7 million people.

The early 1900's. In 1901, a Pan American Exposition was held in Buffalo. The exhibition sought to promote unity and understanding between North and South America.

Theodore Roosevelt, a Republican, served as governor of New York in 1889 and 1900. He supported a number of reform bills, especially in the field of labor. In 1901, Roosevelt became vice president of the United States under President William McKinley. On Sept. 6, 1901, six months after the inauguration, an assassin shot McKinley while the president was attending the Pan American Exposition. McKinley died eight days later, and Roosevelt became president.

The United States entered World War I in 1917. New York City served as the great port from which thousands of American soldiers sailed for and returned from the battlefields of Europe.

The Great Depression of the late 1920's and the 1930's hit New York hard. Unemployment was severe. Men and women sold apples on street corners. Hungry people lined up at soup kitchens, or stood in bread lines that stretched for blocks.

Alfred E. Smith, a Democrat, served as governor of New York from 1919 to 1920 and from 1923 to 1928. He lost to Republican Herbert Hoover in the 1928 presidential election. Franklin D. Roosevelt was governor from 1929 to 1932. He served as president of the United States from 1933 until his death in 1945. Herbert H. Lehman succeeded Roosevelt as governor and served until 1942. Much of the social legislation supported by Governors Roosevelt and Lehman attacked the depression. This legislation later served as a model for federal laws urged by Roosevelt when he was president.

The mid-1900's. New York became a center of the
country's defense industry in the mid-1900s. Factories produced large amounts of war materials during World War II (1939–1945), the Korean War (1950–1953), and the Vietnam War (1957–1975). These materials came from the state's industrial centers—Buffalo, New York City, Rochester, Schenectady, and Syracuse—and hundreds of smaller communities. Growth occurred in several fields, including agriculture, banking, insurance, and manufacturing.

In 1946, the United Nations selected New York City as the site of its permanent home. Construction of UN headquarters was completed in 1952. Two world's fairs were held in New York City during the mid-1900s—in 1939 and 1940 and in 1964 and 1965.

In 1948, New York established the State University of New York (SUNY), its first state university. SUNY has grown into a system of more than 60 campuses.

During the late 1950s, New York and the Canadian province of Ontario developed large hydroelectric projects on the St. Lawrence and Niagara rivers. In 1961, the Niagara Power Plant opened. It is one of the largest hydroelectric facilities in the world.

New York also greatly improved its transportation system. The St. Lawrence Seaway opened in 1959, allowing oceangoing ships to sail to ports on the Great Lakes. In 1960, New York completed the world's longest toll superhighway, the New York State Thruway. This 559-mile (900-kilometer) expressway was renamed the Governor Thomas E. Dewey Thruway in 1964. Also in the 1960s, the federal government completed the New York portion of Interstate 81, stretching 180 miles (290 kilometers) from Pennsylvania to Canada. The 176-mile (283-kilometer) Adirondack Northway was also completed during this time. The scenic northway extends from Albany to Quebec. In 1964, the Verrazano-Narrows Bridge opened in New York City. It has one of the world's longest center spans.

During the 1960s, the Lincoln Center for the Performing Arts was built in New York City. The center serves as a home for some of the outstanding cultural institutions in the United States. These world-famous institutions include the Metropolitan Opera, the New York Philharmonic, the Juilliard School, the New York City Ballet, the New York City Opera, the Film Society of Lincoln Center, the Chamber Music Society of Lincoln Center, the Lincoln Center Theatre, and the School of American Ballet. In addition, two branches of the New York Public Library are located in the center.

The late 1900s. During the early 1970s, many manufacturing plants in New York closed, resulting in the loss of about 600,000 jobs. Many people moved away from the state as a result. However, this outflow of people leveled off during the 1980s, and the population showed an increase during the 1990s. The state's economy experienced a healthy recovery, due mainly to the tremendous growth in service industries and electronics manufacturing.

During the late 1900s, the state continued to maintain its great attractiveness for immigrants, especially Asians and Hispanics. New York ranks second only to California in the number of new immigrants it receives every year. Like other states, New York began to deal with the
long-neglected problem of toxic industrial wastes. It is estimated that New York has over 500 hazardous waste sites that need cleaning. One of the most critical sites is the Love Canal neighborhood of Niagara Falls. In the 1970's and early 1980's, chemical wastes that had leaked from a former disposal site threatened the health of the area's residents. Both the New York state government and the federal government provided financial aid to help move the families from Love Canal to other areas. In 1986, New York voters approved a $1.45-billion bond act to finance environmental projects, chiefly the cleaning up of hazardous waste sites.

In addition to dealing with hazardous wastes, New York faced many other challenges in the late 1980's. These challenges, which continued into the 2000's, included improving social services and housing for the poor and mentally disabled and maintaining the state's extensive highway network. New York leaders also faced the need to provide better education for minority students, to curb drug abuse, and to improve the handling of the state's growing prison population.

The early 2000's. On Sept. 11, 2001, terrorists in hijacked commercial airplanes crashed the planes into the twin 110-story towers of the World Trade Center in New York City. Another hijacked plane crashed into the Pentagon Building, just outside Washington, D.C., and a fourth hijacked plane crashed in a field in Somerset County, Pennsylvania. The two Trade Center towers collapsed to the ground, and part of the Pentagon was destroyed. About 3,000 people were killed. The incidents were the worst terrorist attack in United States history.

Adam V. Burnett and Milton M. Klein

New York, City University of, consists of 10 senior colleges, 7 community colleges, 1 technical college, a law school, a medical school, and a graduate school in New York City. The Mount Sinai School of Medicine is also affiliated with the university.
The 10 senior colleges of the City University of New York are Bernard M. Baruch College, City College, Hunter College, and John Jay College of Criminal Justice, all located in Manhattan; Herbert H. Lehman College in the Bronx; Brooklyn College and Medgar Evers College in Brooklyn; Queens College and York College in Queens; and College of Staten Island on Staten Island. These senior colleges offer liberal arts and science programs leading to bachelor's degrees. The university's technical college, the New York City Technical College, also offers bachelor's degrees.

Master's degrees are offered in business, education, engineering, fine arts, liberal arts, library science, nursing, public administration, social work, and urban planning. The university offers doctor's degrees in 35 fields.
The seven community colleges are Borough of Manhattan, Bronx, Hostos, Kingsborough, LaGuardia, Medgar Evers, and Queensborough. These colleges offer associate degrees in arts and sciences and applied science. In addition, Medgar Evers offers four-year degrees.
The City University of New York is supported by the city, state, and federal governments, and by fees, gifts, and tuition. It gained university status in 1961. The City University of New York is the largest urban system of higher education in the United States.

Critically reviewed by the City University of New York

New York, State University of, is the largest statewide public system of higher education in the United States. The university includes 4 university centers, 13 colleges of arts and science, and 3 health science centers. It also has 5 specialized colleges, 5 colleges of technology, 2 colleges of agriculture and technology, 5 statutory colleges, and 30 community colleges.
The four university centers are in Albany, Binghamton, Buffalo, and Stony Brook. Twelve of the 13 state colleges are in Brockport, Buffalo, Cortland, Fredonia, Geneseo, New Paltz, Old Westbury, Oneonta, Oswego, Plattsburgh, Potsdam, and Purchase. Empire State College is a nonresidential, nontraditional college with a coordinating center in Saratoga Springs. The three health science centers are in Brooklyn, Stony Brook, and Syracuse.

Other professional colleges in the State University of New York system include the College of Environmental Science and Forestry in Syracuse, the College of Optometry in New York City, the Institute of Technology at Utica/Rome, and the Maritime College in the Bronx, a borough of New York City. The statutory colleges are the New York State College of Ceramics at Alfred University and four colleges at Cornell University. The four colleges at Cornell are the New York State School of Industrial and Labor Relations and the New York State Colleges of Human Ecology, Veterinary Medicine, and Agriculture and Life Sciences.

The master's degree is offered at 28 campuses. The four university centers grant the Doctor of Philosophy degree. The Doctor of Medicine is offered at four campuses, and five campuses grant various other medical degrees.
Two-year programs leading to associate degrees are offered at the 30 community colleges. They are also offered at the colleges and institutes of technology at Alfred, Canton, Delhi, and Farmingdale and at the colleges of agriculture and technology at Cobleskill and Morrisville. In addition, the colleges at Alfred, Cobleskill, and Farmingdale offer programs leading to bachelor's degrees. The Fashion Institute of Technology in New York City offers associate, bachelor's, and master's degrees.
The State University of New York was established in 1948. Its headquarters are in Albany.
New York City, the largest city in the United States, is a world center of business, culture, and trade. This photo shows Manhattan Island from the East River. The wide building in the foreground is United Nations Headquarters. Behind it, topped with arches and a spire, is the Chrysler Building.

New York City

New York City is the largest city in the United States and one of the largest in the world. It ranks as one of the world's most important centers of business, culture, and trade. It is also the home of the United Nations (UN). Much of what happens in New York City affects what happens throughout the United States and in other parts of the world.

New York City has a population of about 8 million. It has more than twice as many people as any other city in the United States. In fact, only 10 states—not including New York state—have more people than New York City. Ever since Dutch colonists settled the area at the southern tip of Manhattan Island in 1625, New York has been the destination of immigrants from throughout the world.

During the 1800's and the early 1900's, millions of Europeans seeking a better life in a free land poured into New York City. The Statue of Liberty, which was erected in New York Harbor in 1886, became the symbol of this new life.

Since the mid-1900's, many blacks from the Southern States and Spanish-speaking Americans from Puerto Rico have moved into the city. In the 1980's and 1990's, a new wave of immigrants flowed into New York City. These immigrants included many people from China, Central America, and Caribbean lands.

The business, financial, and trading organizations in New York City play a major role in the economy of the nation and of the world. The banks, stock exchanges, and other financial institutions in New York City's famous Wall Street area help provide the money used by most large United States corporations. The skyscrapers that form the spectacular New York skyline house the home offices of many national and international business firms. The docks, the warehouses, and the shipping companies that line New York's huge natural harbor handle much of the nation's imports and exports. Two major airports serve numerous international airlines.

As a cultural center, New York City has no equal in the United States. Most of the publishing houses that select and produce the nation's books have their headquarters in New York. The city's world-famous Broadway area is the center of professional theater in the United States. New York is also the home of some of the nation's largest museums and art galleries. The city displays beautiful churches in the Gothic Revival style, gleaming modern skyscrapers, and other interesting styles of architecture. A great number of outstanding orchestras and opera and dance companies give performances at the Lincoln Center for the Performing Arts. Because of its prominence as a cultural and entertainment center, New York City is sometimes called the "Big Apple."

But along with all its greatness, New York City has many serious problems. Thousands of immigrants have not found the opportunities they had hoped for in New York. About a million New Yorkers receive welfare aid, and thousands live in slums. Other problems include air pollution, traffic jams, crime, drug abuse, racial conflicts, and increases in the cost of living in the city. All these
problems are driving many families—especially middle-class families—to the suburbs.

New York City remains one of the most interesting and exciting cities in the United States. In fact, many people consider it the most fascinating city in the world.

The city

New York City lies in the southeast corner of New York state at the mouth of the Hudson River. It covers about 322 square miles (834 square kilometers). The city is divided into five areas called boroughs—Manhattan, the Bronx, Queens, Brooklyn, and Staten Island. Each is a county of New York state.

Manhattan, the smallest borough in area, covers 82 square miles (212 square kilometers). It occupies a long, narrow island bordered by the Hudson River on the west, the East River on the east, the Harlem River on the north and northeast, and Upper New York Bay (the mouth of the Hudson) on the south.

The Bronx lies across the Harlem River from Manhattan and covers 44 square miles (114 square kilometers). It extends north along the Hudson River and east along the East River. It is the only borough not separated from upstate New York by water.

Queens, the largest borough in area, occupies 112 square miles (290 square kilometers) on the northwest corner of Long Island. The East River separates Queens from the Bronx to the north and from Manhattan to the west.

Brooklyn covers 82 square miles (212 square kilometers) on the southwest tip of Long Island. It lies south and southwest of Queens and southeast of Manhattan across the East River.

Staten Island, formerly called the borough of Richmond, occupies a 60-square-mile (155-square-kilometer) island in Upper and Lower New York bays. It lies west of Brooklyn and southwest of Manhattan.

The state of New Jersey is directly west of New York City. It lies across two waterways, Arthur Kill and Kill Van Kull, from Staten Island; across Upper New York Bay from Brooklyn; and across the Hudson River from Manhattan and the Bronx.

Each of New York City's boroughs has a large population, important businesses and industries, and many fine educational and cultural institutions. Within the five boroughs are more than 100 neighborhoods, such as Manhattan's Chinatown, Greenwich Village, and Harlem. These neighborhoods are not official government units. They have similar types of housing or people with similar backgrounds or lifestyles.

The New York City metropolitan area spreads into northeastern New Jersey and southern New York state. Hundreds of thousands of people who work in New York live in suburban residential communities in the city's metropolitan area. Many industrial cities also lie in the area surrounding New York City.

Manhattan is the oldest and most important borough of New York City. It is about 13 1/2 miles (21.7 kilometers) long and 2 1/2 miles (3.8 kilometers) wide at its widest point. But about 1 1/2 million people live there.

The borough of Manhattan has New York City's tallest buildings, some of the nation's largest schools and colleges, and the world's most famous financial and theatrical districts.

Facts in brief

Population: City—8,008,278. Metropolitan area—9,314,235. Consolidated metropolitan area—21,199,865 (12,689,865 in New York, 6,661,750 in New Jersey, 1,801,948 in Connecticut, and 46,302 in Pennsylvania).

Area: City—322 mi² (834 km²). Metropolitan area (excluding inland water)—1,148 mi² (2,973 km²). Consolidated metropolitan area (excluding inland water)—10,457 mi² (27,084 km²).

Climate: Average temperature—January, 33 °F (1 °C); July, 74 °F (23 °C). Average annual precipitation (rainfall, melted snow, and other forms of moisture)—44 in (112 cm). For information on the monthly weather in New York City, see New York (Climate).

Government: Mayor-council. Terms—4 years for the mayor, the City Council president, controller, and the 51 members of the City Council.

Founded: 1625. Incorporated as a city in 1653.

New York City's flag is blue, white, and orange. The colors represent the area's Dutch flag of colonial times.

The seal of New York City features an American eagle, an English sailor, and a Manhattan Indian.

New York City lies at the center of a megalopolis, a group of metropolitan areas. These urban areas extend from Boston to Washington, D.C.
Manhattan is an area of many sharp contrasts. Some of the richest people in the United States live in its beautiful town houses and luxurious high-rise apartment buildings. But some of the nation’s poorest people occupy its tenements (shabby apartment buildings) and low-rent public housing projects. Most of Manhattan is covered with concrete and asphalt, and skyscrapers make many of its streets look like deep canyons. But the borough’s Central Park provides 840 acres (340 hectares) of grass, trees, and rolling hills. Manhattan has some of the world’s most exclusive shops and largest department stores. They attract shoppers from all parts of the country. But the borough also has tiny neighborhood shops that sell to nearby residents.

New York City’s Financial District lies at the southern tip of Manhattan and is centered on Wall and Broad streets. Many large banks, brokerage houses, and stock exchanges have their headquarters along the district’s narrow streets. The World Trade Center is in the Financial District along the Hudson River. Twin 110-story towers that once were part of the center were destroyed in 2001 in the worst terrorist attack in U.S. history.

Broadway, one of the city’s longest and best-known streets, begins in the Financial District and runs north and northwest across Manhattan. On the east side of Broadway, a few blocks north of the Financial District, stands the Municipal Civic Center. The center includes City Hall, courthouses, and other government buildings.

Residential and commercial neighborhoods lie to the north and northeast of the Municipal Civic Center. These neighborhoods include Chinatown, Little Italy, and the Lower East Side. Both Chinatown and Little Italy have some of the city’s oldest tenements. They also have many restaurants that specialize in Chinese or Italian food. For many years, most immigrants to New York City have first settled on the Lower East Side because of its many low-rent tenements. Jews once made up the largest group in the area. Today, Puerto Ricans are the largest single group on the Lower East Side. Other groups, especially students and artists, have also been attracted to the Lower East Side by the low rents.

Greenwich Village lies west of Broadway and the Lower East Side. It attracts artists, writers, musicians, actors, and other people in the arts. The Village has a variety of housing, many interesting shops and art galleries, and several small theaters. Many people in the arts also live in the SoHo area, south of the Village.

North of Greenwich Village, Manhattan is laid out in a regular pattern of cross streets. Avenues run north and south, and numbered streets run east and west. Broadway cuts diagonally across this pattern.

Some of New York City’s largest department stores are in the Herald Square and Greeley Square areas, where Broadway crosses the Avenue of the Americas (formerly Sixth Avenue). East of the department stores, on 34th Street, is the famous, 102-story Empire State Building, for many years the world’s tallest building. The Garment District, center of the city’s large clothing industry, lies north of Herald and Greeley squares.

The intersection of Broadway and Seventh Avenue,
between 42nd and 47th streets, forms world-famous Times Square, the heart of the New York Theater District. Since the late 1960's, the Times Square area has been undergoing redevelopment. A number of large office buildings have been constructed there. But the area remains the Theater District because many of the new buildings house theaters. Plans for further redevelopment also seek to maintain the area's theatrical activities.

United Nations Headquarters occupy 18 acres (7.3 hectares) along the East River between 42nd and 48th streets. The UN's beautiful modern buildings have become New York City landmarks.

Rockefeller Center is another of the city's landmarks. It lies on Fifth Avenue between 48th and 51st streets. The center consists of 21 buildings covering about 25 acres (10 hectares). It is the world's largest privately owned business and entertainment facility. The center's buildings include the RCA Building, which is 850 feet (259 meters) high, and the 5,900-seat Radio City Music Hall, the world's largest indoor theater. Many of New York City's finest stores line Fifth Avenue both north and south of Rockefeller Center.

Central Park, which runs from 59th to 110th streets between Fifth Avenue and Central Park West, separates Manhattan's Upper East Side and Upper West Side. The Upper East Side has long been the most fashionable neighborhood in Manhattan. At one time, the area had many town houses that were owned by the city's richest residents. Today, cultural organizations and United Nations delegations occupy many of these buildings, and

New York City

This map shows the five boroughs of New York City—the Bronx, Brooklyn, Manhattan, Queens, and Staten Island. These boroughs are also counties of the state of New York. County names appear in parentheses under each borough name.
Outdoor food markets and other small shops serve customers in many New York City neighborhoods. This fruit and vegetable market is in the Little Italy section of Manhattan.

most of the people in the area live in luxurious apartment buildings. The Upper West Side has been chiefly a middle-class neighborhood. It includes many apartment houses, hotels, tenements, and long blocks of brick and brownstone row houses. In the late 1900s, however, housing prices rose sharply in the area. Many of the Upper West Side's best buildings now rival the Upper East Side in price.

Harlem, the best-known black community in the United States, lies north of Central Park. It has long been a center of African American business and cultural activi-

ties. A series of model housing projects extends along the Harlem River at the northern edge of Harlem. But much of the area consists of tenements.

Morningside Heights, the site of Columbia University and several other educational, cultural, and religious institutions, lies west of Harlem along the Hudson River. City College of the City University of New York lies north of Morningside Heights, in an area that was once the country estate of the American statesman Alexander Hamilton.

Washington Heights and Inwood are at the northern tip of Manhattan. Both have aging tenements, as well as modern housing projects. Washington Heights was formerly inhabited by many Jewish immigrants who fled Europe to escape Nazi leader Adolf Hitler's brutal persecution of Jews in the 1930s and 1940s. Today the area is largely populated by immigrants from the Dominican Republic. The Columbia-Presbyterian Medical Center; Yeshiva University; and the Cloisters, a museum featuring European art of the Middle Ages, are in Washington Heights.

Brooklyn has more people than any other borough of New York City. If Brooklyn were an independent city, its population of about 2 1/2 million would make it the nation's fourth largest city.

Brooklyn is an important port and industrial center. Hundreds of ships carry freight to and from Brooklyn's docks each year. The borough's factories, most of which are along the waterfront, make a wide variety of goods. Housing in Brooklyn ranges from large houses and towering apartment buildings to small cottages and rundown rooming houses. But most Brooklynites live in row houses and small apartment buildings that line the streets throughout the borough.

Downtown Brooklyn, the borough's main business and shopping district, lies near the approaches to the Brooklyn and Manhattan bridges. These two bridges are the main links between Brooklyn and Manhattan. A third

Harlem, a section of Manhattan, has long been a center of African American business and cultural activities. Shoppers on 125th Street, shown here, pass by a theater that dates from the early 1900s.
Manhattan

This map shows the central and lower parts of Manhattan.
bridge, Williamsburg Bridge, also connects the two boroughs. Brooklyn's downtown area has large department stores, tall office buildings, and several schools and colleges. Flatbush Avenue, one of the main downtown streets, begins at the Manhattan Bridge and runs through the heart of the borough.

Two of Brooklyn's oldest neighborhoods, Brooklyn Heights and Cobble Hill, lie along the East River west of the downtown area. These neighborhoods have more than 1,000 houses over 100 years old. Many of the houses stand on handsome, treelined streets and are carefully preserved.

The site of the former U.S. Naval Shipyard, which had been one of Brooklyn's chief industries, lies northeast of downtown. The Navy gave up the yard in 1968, and the area is now being made into an industrial park for factories, shipbuilding, and warehouses.

Bedford-Stuyvesant, east of the downtown area, is the largest black neighborhood in New York City. Blocks of well-kept row houses and many fine churches are found throughout the neighborhood. In contrast, Brownsville, a black and Puerto Rican neighborhood which lies southeast of Bedford-Stuyvesant, is the city's worst slum area. It has few well-maintained areas, and many of its buildings are abandoned and decaying.

Prospect Park, in the center of Brooklyn, is one of the finest landscaped parks in the nation. The park is designed so that its lakes, meadows, woods, and other features look larger than they are. Flatbush, once a fashionable suburb of Brooklyn, begins on the southeast edge of the park. Large homes built during the 1890's and early 1900's line many of its shaded streets.

Coney Island lies at the southern tip of Brooklyn. The area once was an island, but land has been filled in to make it a peninsula. In summer, many New Yorkers ride subways to Coney Island's beaches and to its famous Boardwalk, which has side shows, souvenir stands, and other attractions. At one time, Coney Island also had great amusement parks, but they have been replaced by housing developments. In the late 1900's, large numbers of immigrants from Russia settled in Coney Island.

The Bronx has a population of about 1½ million and is chiefly a residential borough. The western part of the Bronx consists of a series of hills and valleys crossed by boulevards. A major boulevard in the Bronx, the Grand Concourse, runs north and south through the area. It is lined with apartment houses, commercial buildings, and stores. The eastern section of the borough is a broad plain, with peninsulas extending into the East River and Long Island Sound.

Bronx Park lies in the center of the Bronx. It includes the Bronx Zoo (officially the International Wildlife Conservation Park), one of the best-known zoos in the United States, and the New York Botanical Garden, an important scientific institution.

Fordham University and Lehman College have handsome campuses to the west of Bronx Park. The campus of Bronx Community College of the City University of New York includes the Hall of Fame, which honors the memory of great Americans (see Hall of Fame).

One of the most fashionable neighborhoods in the Bronx is Riverdale, in the northwest corner of the borough along the Hudson River. It has tall apartment buildings, estates and other large homes, and exclusive pri-
Queens is the largest borough in area. It has many unattached single-family homes, large apartment buildings, housing projects, and busy expressways. Much of the borough's development has occurred since the 1940's.

Queens, with about $2 \frac{1}{2}$ million residents, ranks second in population among New York City's boroughs. Queens grew rapidly from 1910 to 1930, when subways were extended, new highways were built, and two major airports were developed in the borough. Today, huge housing developments and busy expressways are the major features of Queens.

Much of the borough's industry is concentrated near the East River in an area called Long Island City. The area lies just south of the Queensboro Bridge, which connects Queens and Manhattan. It has giant rail yards and many industrial plants and warehouses. Maspeth southeast of Long Island City, also has large industrial plants, as well as pleasant residential areas.

Forest Hills lies near the center of Queens. Within this neighborhood is Forest Hills Gardens, an attractive housing and shopping area built in 1910. Forest Hills Gardens was intended for families with middle incomes. But it immediately became—and has remained—a community for the wealthy.

Northeast of Forest Hills is Flushing Meadow-Corona Park, site of the New York World's Fairs of 1939-1940 and 1964-1965. The park has several features left from the fairs, including a botanical garden, an indoor ice-skating rink, and a science museum.
La Guardia Airport, one of New York City's two main airports, is northwest of Flushing Meadow-Corona Park, across Flushing Bay. The neighborhood of Flushing, northeast of the park, has a busy shopping area and many large apartment houses.

Jamaica, in southeastern Queens, is one of the borough's chief commercial centers. It has large shopping and business areas and both rich and poor residential sections.

John F. Kennedy International Airport, the city's largest airport, lies immediately south of Jamaica. It has been expanding since 1942 and has become the borough's largest single source of employment.

Rockaway is a long peninsula that forms the southern border of Jamaica Bay. It has a sandy beachfront, attractive private homes, and modern apartment buildings. It also has many summer cottages, some of which are occupied the year around.

Staten Island has about 440,000 residents, making it the smallest borough in population. It is the only borough not connected to Manhattan by a bridge or a tunnel. Until the completion of the Verrazano-Narrows Bridge in 1964, much of the island consisted of small farms and undeveloped areas. The bridge, which connects Staten Island with Brooklyn, has led to the construction of new housing and to industrial growth. But many communities on Staten Island still look more like suburban towns than like sections of a major city.

St. George, on the northeast tip of Staten Island, serves as the downtown section of the borough and is the site of the Staten Island Ferry Terminal. The famous ferries carry automobiles and passengers between Staten Island and Manhattan and provide the only direct link between the two boroughs. A U.S. Coast Guard station, government and private office buildings, and a variety of stores are also in St. George.

The eastern shore of Staten Island is a decaying industrial area. But there are handsome homes and several colleges on the wooded hills just inland.

Parks and beaches line the southeastern and southern coasts of the island. Richmond Town, in the center of Staten Island, is being restored to show how it developed during the 1600's, 1700's, and 1800's.

The industrial communities of Mariners Harbor and Port Richmond lie on the north coast of Staten Island. One of the three bridges that connect Staten Island and New Jersey is near Mariners Harbor. The others are on the northwest coast and near the island's southern tip.

Small islands. There are several small islands in the waters surrounding New York City. The most famous is Liberty Island, site of the city's greatest landmark—the Statue of Liberty. Ellis Island lies near Liberty Island. The United States Immigration Service used the island until 1954 as a port of entry and a detention and deportation center. Liberty and Ellis islands now form the Statue of Liberty National Monument. Governors Island, at the mouth of the East River, was the site of a military installation from the late 1700's until 1997. Roosevelt, Wards, Randalls, and Rikers islands are in the East River. Hospitals, prisons, and other institutions have been built on these islands. An aerial cable car system links Roosevelt Island and Manhattan. See Ellis Island; Liberty Island.

Metropolitan area. The New York City Metropolitan Statistical Area consists of the five boroughs and Putnam, Rockland, and Westchester counties in southern New York.

New York City's metropolitan area is the largest of the metropolitan areas that make up the New York-Northern New Jersey-Long Island consolidated metropolitan area. This region also includes the Dutchess County, Nassau-Suffolk, and Newburgh metropolitan areas in New York, six metropolitan areas in New Jersey, five metropolitan areas in Connecticut, and one county in Pennsylvania. The region has about 21 million people.

Many communities in the New York area are commuter suburbs. Their residents work in New York City and commute by automobiles, buses, ferries, railroads, and subways. Some of these suburbs, such as White

New York's Fifth Avenue is one of the city's famous shopping centers. It includes a number of stores known for their expensive merchandise. Fifth Avenue is also the site of such famous landmarks as Rockefeller Center, St. Patrick's Cathedral, and Trump Tower.
Plains in Westchester County, have become important centers of business and shopping outside the central city. Other communities in the New York area are industrial cities. They provide enough jobs so that most of their residents work in the communities themselves. Some of these industrial communities, such as Newark and Jersey City in New Jersey, are also experiencing the problems of pollution, poverty, and urban decay that affect New York City.

People

The people of New York City represent nearly all nationalities. During the 1650's, only about 1,000 people lived in the Dutch colony of New Amsterdam on Manhattan Island. But even then, 18 languages were spoken in the colony. Since that time, people from throughout the world have brought their skills, traditions, and ways of life to New York City.

People move to New York City for many reasons. Many are attracted by the city’s job opportunities. Other people come to attend the city’s schools and colleges or to enjoy its many cultural activities. Still others come simply because they want to be a part of a large, exciting city.

Ethnic groups. Five ethnic groups—black, Irish, Italian, Jewish, and Puerto Rican—make up about 80 percent of New York City’s people. Neighborhoods consisting largely of people from these and many smaller groups are scattered throughout the city. Originally, most of the people in ethnic groups shared direct ties to a country, a language, or a common past with other members of their group. Today, such ties are less common. But the people still have some unity through such things as common religious beliefs and common economic interests.

Blacks are the largest ethnic group in New York City and make up about 27 percent of the city’s population. New York has about 2,100,000 blacks, more than any other city in the United States. Most of the blacks are migrants—or the children of migrants—from the rural South. But many have also come from the West Indies. A large number of New York City’s blacks live in poor neighborhoods. Many of them have been prevented from leaving the ghetto areas by discrimination in jobs and housing and by a lack of education. But more and more black New Yorkers are becoming part of the city’s middle class. Thousands of blacks live in racially integrated areas, and thousands more live in middle-class black neighborhoods.

Jews make up about 15 percent of the population of New York City. New York’s Jews come from many countries. They are considered to be an ethnic group, however, because most of them live in Jewish neighborhoods and have similar religious and social beliefs. Many Jews own businesses. Many others work in garment factories, in offices, and in the legal, medical, and teaching professions.

About 14 percent of New York City’s people are of Italian ancestry. New York Italians are known for their well-kept homes and for their close neighborhood ties. They are the largest single group in the city’s construction industry, and they play a key role in the restaurant and the wholesale and retail food-marketing industries. Many Italians have civil service jobs in the city’s park, public works, sanitation, police, and fire departments.
Most of New York City's Italians belong to the Roman Catholic Church.

Puerto Ricans make up about 12 percent of New York City's population. They are the largest of several Spanish-speaking ethnic groups in the city. Large numbers of Puerto Ricans began to come to New York in the 1950's. Many of them found jobs as unskilled workers, especially in hospitals, hotels, and restaurants. At first, nearly all Puerto Ricans lived in East Harlem in Manhattan. But today, Puerto Rican neighborhoods are found in all the boroughs. Neighborhood associations, large church organizations, and the public school system have all developed programs to help newly arrived Puerto Rican people learn English and adjust to life in the city.

The Irish have traditionally been active in New York City's political life. During the late 1800's and early 1900's, they controlled the city government. But the percentage of Irish people in the city has dropped from 30 percent in 1870 to about 9 percent today. As a result, the Irish have lost much of their political power. But they are still the largest single group employed by New York City's police and fire departments. The Irish are also among the leaders of the Roman Catholic Church in the city.

New York City has many other ethnic groups besides the five major ones. Other large ethnic groups in the city include Chinese, English, Germans, Greeks, and Russians. Housing in New York City differs in several ways from that in most other cities of the United States. About 65 percent of New York's families live in apartment buildings or hotels. In other cities, most people live in one- or two-family houses. About 70 percent of the families in New York rent their homes. In other U.S. cities, most families own their homes. About half of the housing in New York City was built before 1940. Most other cities in the United States have a far larger percentage of newer housing.

New York City has long been a leader in housing reform. In 1867, New York state, at the request of the city, passed the nation's first tenement house law. The law set minimum standards for room sizes and for ventilation and sanitation facilities. In 1943, the city passed a rent control law to protect tenants in privately owned buildings from unfair rent increases. Rent control laws passed in the 1970's were intended to help landlords make a reasonable profit. But many landlords complain that the higher rents they may charge do not cover rising costs. New York City has also built many public housing projects. Today, about 170,000 low-income families live in city-owned public housing.

But housing remains one of New York City's most serious and difficult problems. Many old buildings are becoming unusable, and the demand for new housing, especially among poor people, is rapidly increasing. Yet steadily rising construction costs and a lack of large areas of open land make the development of new housing difficult.

Education. New York City has the largest public school system of any city in the United States. The public school system includes more than 960 schools with more than 1 million students. An additional 300,000 students attend hundreds of privately operated schools in New York City.

The mayor controls the city's public school system. The mayor appoints a chancellor to oversee the system and appoints 8 members of a 13-member Board of Education. The five borough presidents appoint the other 5 board members. The 5 members appointed by the borough presidents must be parents of students attending a public school in the system.

New York City has neighborhood high schools like those found in most other cities. But it also has a wide variety of specialized high schools that prepare students for a specific occupation or for further training at the college level. These institutions include schools of automobile mechanics, aviation, the performing arts, printing, and science. Grade schools in poor neighborhoods have special programs to aid underprivileged children and children who do not speak English.

Many of New York City's colleges, universities, and other institutions of higher learning are world famous. One of the largest universities in the world, the City University of New York, is operated by the city with state and federal assistance. The university consists of nine senior colleges, seven community colleges, a graduate school, a law school, a medical school, and a technical school. The university has a total enrollment of about 180,000 students.

Columbia University, founded in 1754, is the oldest private university in New York City. The city's largest private university is New York University. Fordham and St. John's universities are important Roman Catholic schools.

New York City also has many smaller and more specialized institutions of higher education. The New School University deals mainly with adult education. Rockefeller University specializes in advanced research in biology and medicine. Pratt Institute and Cooper Union are largely devoted to architecture, engineering, and the fine arts. Other schools specialize in law, medicine, and social work.

Social problems. New York City has many of the same problems other cities have. But it is so much larger than other cities that the problems are greatly magni-
tied. New York's major social problems include poverty, crime and drug addiction, and racial conflict.

Poverty is one of New York City's most expensive problems. The city budgets more than $4 billion a year on welfare programs to provide food, clothing, housing, medical care, and other benefits for about 1½ million people. Yet unskilled immigrants continue to move into the city, while the demand for unskilled labor continues to decline. As a result, the problem of poverty is difficult to solve.

Because of its large population, New York City has more crime than any other U.S. city. But the crime rate—the number of crimes committed for every 100,000 residents—is actually lower in New York than in many other cities. New York's crime and drug addiction problems are closely related. About half the drug addicts in the United States live in New York City. They commit many of the city's burglaries and attacks on individuals to get money for drugs.

Racial conflicts in New York City have had many causes. A major cause has been discrimination against blacks, Puerto Ricans, and other minority groups in jobs and housing. Many minority group residents have had trouble obtaining well-paying jobs. Many also have had difficulty moving out of segregated neighborhoods and into neighborhoods where most of the people are white and of European ancestry. When members of a minority group have begun moving into such a neighborhood, the white residents often have begun moving out. In this way, segregated housing patterns have continued, and the chances for conflicts between the groups have increased.

Economy

New York City is one of the world's most important centers of industry, trade, and finance. Businesses, industries, and government agencies in the metropolitan area provide about 7 million jobs. About 3½ million of these jobs are within the city itself.

The economies of both New York City and its suburbs are growing. But since the 1940's, the economy of the suburban area has grown much faster than that of the city. The construction of new highways, a growing labor force, and the availability of land in the suburbs have led many businesses and industries to move from the crowded central city to the suburbs.

The types of jobs available in New York City have also been changing since the 1940's. The number of jobs for unskilled workers has decreased greatly because many industries have moved to the suburbs. This decrease has created a serious economic problem because most immigrants to the city are unskilled. At the same time, the number of jobs for skilled workers, especially office workers, has increased. But many of these jobs are being filled by people who live in the suburbs and commute to the city.

Industry. New York City ranks third after Los Angeles-Long Beach and Chicago among the leading manufacturing centers in the United States. It has about 17,000 industrial plants. They employ about 430,000 workers. The most important industries are (1) printing and publishing and (2) clothing production.

New York City is one of the nation's chief printing and publishing centers. It has more printing plants than any other U.S. city. New York does about a sixth of the nation's printing and publishing. It publishes about a third of the books published in the United States. The city's printing and publishing industry employs about 93,000 people.

New York City's clothing industry is centered in Manhattan's famous Garment District, southwest of Times Square. There, hundreds of factories employ about 119,000 people. But the garment industry has been declining in New York City. Many factories have closed. Other factories have left the Garment District because of the rising costs of doing business in the heart of Manhattan.

Other leading manufacturing industries include those that produce chemicals, food products, furniture, machinery, metal products, paper products, and textiles. The construction industry is also important. About 87,000 people in the city work in jobs related to the industry.

Trade. New York City's port, officially called the Port of New York and New Jersey, is one of the world's largest and busiest seaports. It employs about 200,000 people. The port ranks second to the Port of Los Angeles in total value of cargo handled annually. The port's cargo includes foreign imports and exports, and goods going to and coming from other U.S. ports.

New York City's port activity has been declining since the late 1940's. One reason for the decline in port activity has been the growth of other international seaports in the United States, especially along the Great Lakes. The opening of the St. Lawrence Seaway in 1959 allowed ships that previously docked in New York to reach Great Lakes ports.

Large amounts of cargo are also handled at airports in the New York City area. Foreign air freight goes through Kennedy Airport and nearby Newark International Airport in New Jersey. Domestic cargo is handled at Kennedy, La Guardia, and Newark airports.

The Garment District in Manhattan is the center of New York City's important clothing industry. The district's streets are crowded with workers moving racks of clothing.
The Port Authority of New York and New Jersey, a self-supporting agency of the states of New York and New Jersey, operates New York City’s major airports and docking facilities, as well as several other transportation facilities. See Port Authority of New York and New Jersey.

Wholesale trade plays an important part in New York City’s economy. The city has about 20,300 wholesale firms. They employ over 240,000 people. The city’s wholesale grocery and dry-goods businesses are the largest in the United States.

Retail business firms in New York City have more than 370,000 employees. The nation’s largest retail center is in midtown Manhattan. The department stores and specialty shops in midtown Manhattan are known throughout the world.

Finance. More of the nation’s largest and most important financial institutions have their headquarters in New York City than in any other city. Banks, brokerage houses, insurance companies, real estate firms, stock exchanges, and other financial organizations in New York employ about 495,000 people. Unlike most industries in the city, the financial organizations offer a steadily increasing number of jobs.

The most famous financial institution in New York City is the New York Stock Exchange, at the corner of Broad and Wall streets in the heart of the Financial District. It is the largest stock exchange in the United States. The American Stock Exchange, one of the nation’s largest exchanges, is also in the Financial District. Many large brokerage houses have their headquarters near the exchanges.

New York City’s banks are among the biggest in the world. These banks help finance business ventures throughout the United States and in many parts of the world. The largest of the city’s banks are in the Financial District.

Transportation. New York City has a huge, complicated transportation system. Much of the system is centered in the area of Manhattan that is south of Central Park. About 3.5 million people travel to and from that area each working day. Nearly all forms of air, land, and water transportation serve the city.

An extensive highway system has been developed to carry automobiles, buses, and trucks into, out of, and through New York City. The city’s major expressways include the Major Deegan Expressway in the Bronx, the Shore and Gowanus parkways in Brooklyn, and Grand Central Parkway and the Long Island Expressway in Queens. Franklin D. Roosevelt Drive carries traffic along the eastern edge of Manhattan.

New York City includes 65 square miles (168 square kilometers) of inland water, so many bridges and tunnels are needed to link the city’s boroughs. The famous Brooklyn Bridge crosses the East River and connects Brooklyn and the southern tip of Manhattan. It was completed in 1883 and declared a national historic landmark in 1964. In addition to the Brooklyn Bridge, six other bridges cross the East River. They are, from south to north, the Manhattan, Williamsburg, Queensboro, Triborough, Bronx-Whitestone, and Throgs Neck bridges. The Y-shaped Triborough Bridge links Manhattan, the Bronx, and Queens.

The Harlem River is spanned by High Bridge, Harlem Bridge, Henry Hudson Bridge, Alexander Hamilton Bridge, and several smaller bridges. High Bridge, which was opened in 1848, is one of the oldest bridges in the city.

One bridge, the George Washington Bridge, crosses the Hudson River and connects Manhattan and New Jersey. The Bayonne Bridge stretches 1,675 feet (511 meters) over Kill Van Kull channel between Staten Island and New Jersey. It has one of the longest arch spans in the world. Goethals Bridge and Outerbridge Crossing, which cross Arthur Kill channel, also connect Staten Island and New Jersey.
The Verrazano-Narrows Bridge, which links Staten Island and Brooklyn, opened in 1964. Its 4,260-foot (1,298-meter) suspension span is one of the longest in the world.

The Queens Midtown Tunnel runs under the East River and connects Manhattan and Queens. The 9,117-foot (2,779-meter) Brooklyn-Battery Tunnel links the southern tip of Manhattan with Brooklyn. The Lincoln and Holland tunnels run under the Hudson River between Manhattan and New Jersey. In addition to these tunnels for motor vehicles, several tunnels carry subway trains under the East River. Four rapid transit tunnels called the PATH tunnels run under the Hudson River between Manhattan and New Jersey. See Hudson River tunnels.

New York City has three subway systems. They operate on about 230 miles (370 kilometers) of track. The Interborough Rapid Transit (IRT), the city's first subway, opened in 1904. The IRT operates in Manhattan and in a large part of the Bronx. It has branch lines into Brooklyn and Queens. The Independent Subway (IND) has lines in all the boroughs except Staten Island. The Brooklyn-Manhattan Transit Company (BMT) has lines in Brooklyn, Manhattan, and Queens. Buses operate throughout the city. The New York City Transit Authority, a combined city and state agency, controls all the subways and most bus lines that operate in the city. Crowded Manhattan is famous for its huge fleet of taxicabs.

Two major railroad stations serve New York City—Grand Central Terminal (sometimes called Grand Central Station) at 42nd Street and Park Avenue and Pennsylvania Station on 31st Street at Seventh Avenue. In the mid-1960s, the upper level of Penn Station was torn down and replaced by Madison Square Garden, but trains continue to operate beneath street level. Before the rapid growth of air travel in the 1930s, hundreds of thousands of railroad passengers from all parts of the country passed through Grand Central and Penn stations each day. Today, hundreds of thousands of people still use the stations. Most of them, however, are commuters.

La Guardia, Kennedy, and Newark airports handle most of New York City's commercial air traffic. La Guardia serves domestic and Canadian airlines, and Kennedy and Newark serve domestic and international airlines. The New York City area also has numerous smaller airports.

Communications. New York City is the nation's most important center for mass communications. More publishing and broadcasting companies have their headquarters in New York than in any other city in the United States.

Three general newspapers—the New York Daily News, the New York Post, and The New York Times—are published daily in New York City. The Times is one of the world's best-known papers and is often used as a reference source. The city has many community, foreign-language, and trade and union papers. Daily papers printed in Spanish, Russian, Polish, Greek, and Chinese have large circulations. The Wall Street Journal is the major business paper. A national newspaper, its circulation of about 2 million is the largest of any paper in the United States.

Most major national magazines and many specialized magazines have their editorial offices in New York City. New York also has more book publishers and advertising agencies than any other city.

New York City has nearly 60 radio and television stations. It serves as the headquarters of three of the nation's four major broadcasting networks. The three networks are Capital Cities/ABC Inc., CBS Inc., and the National Broadcasting Company (NBC). They provide both television and radio programming to stations throughout the United States. The fourth network—Fox Broadcasting Company—originates many of its television programs from a studio in New York City.

Cultural life and recreation

New York City ranks as one of the world's greatest cultural centers. It has many art galleries, drama and dance groups, musical and literary societies, and other cultural organizations. It also has some of the world's

The Theater District is near Times Square. Its many playhouses are called Broadway theaters. Some theaters feature musicals, and others specialize in comedies and serious dramas. Theatergoers line up in front of the Eugene O'Neill Theatre in this picture.
finest concert halls, museums, and theaters. Many of the nation's greatest actors, artists, musicians, poets, and writers live in New York.

There are several reasons for New York City's leading position as a cultural center. Many of the city's wealthy residents have long given financial support to cultural activities. Traditionally, the city has also offered people in the arts an atmosphere that encourages freedom of expression. In addition, New York's many advertising agencies, broadcasting and film studios, recording companies, and publishing houses have provided jobs that attract creative people.

The arts. Nearly all the arts thrive in New York City. Many new styles in American drama, literature, music, and painting have developed in New York and then spread to the rest of the country.

One of New York City's most famous and popular forms of art is the theater. Most important American plays and musical comedies have their premieres in the city's famous Theater District. The theaters in this district are called Broadway theaters, though few are actually on that street. Most are on side streets near Times Square. Many plays and musicals are also presented in off-Broadway and off-off-Broadway theaters in Manhattan and Brooklyn.

Musical organizations in New York City include the New York Philharmonic, one of the world's great symphony orchestras, and the Metropolitan Opera Association, an outstanding opera company. Both the orchestra and the opera company perform at the Lincoln Center for the Performing Arts. Lincoln Center also houses the New York City Ballet, the New York City Opera, and the Juilliard School of Music. The New York City Center of Music and Drama on West 55th Street offers a variety of fine arts programs. Many concerts are held at Carnegie Hall, near Central Park. The JVC Jazz Festival New York presents jazz concerts in the city for several days in late June and early July.

Thousands of artists live and work in New York City. They display and sell their paintings, sculptures, and other works of art in the city's dozens of galleries. Many artists have made roomy studios in abandoned warehouses and factories in Manhattan. Most of the buildings were abandoned by industries that moved to suburban areas.

Architecture. New York's best-known style of architecture is the towering skyscraper. The giant buildings that form Manhattan's dramatic skyline are famous throughout the world.

One of the oldest and most famous skyscrapers in New York is the Flatiron Building, on 23rd Street where Broadway crosses Fifth Avenue. The 21-story building was completed in 1903. It has a triangular shape like that of an old-fashioned flatiron.

During the 1930's, several famous skyscrapers were built in New York City. The most famous, the 102-story Empire State Building, was completed in 1931. The Empire State Building ranked as the tallest building in the world for many years. The 77-story Chrysler Building at Lexington Avenue and 42nd Street and the 70-story RCA Building in Rockefeller Center were also completed in the 1930's.

Many glass-walled skyscrapers have been built in New York since the 1950's. These buildings include the United Nations Secretariat along the East River at 44th Street, Lever House on Park Avenue between 53rd and 54th streets, and the Seagram Building on Park Avenue between 52nd and 53rd streets.

Several New York City churches are famous for their Gothic Revival style of architecture. They include the

Lincoln Center for the Performing Arts houses the New York Philharmonic, the Metropolitan Opera, the New York City Ballet, and several other cultural organizations.
The Metropolitan Museum of Art, which occupies four city blocks in New York, ranks as the largest art museum in the United States. Patrons enjoy viewing a vast array of paintings, sculptures, and other artworks in the "Met," as the museum is often called.

Neighborhood festivals allow New York City residents to enjoy cultural activities near their homes. The festivals are free and feature various types of music and other entertainment.

Episcopal Cathedral of St. John the Divine between 110th and 113th streets near Broadway, the Roman Catholic St. Patrick's Cathedral on Fifth Avenue between 50th and 51st streets, and the interdenominational Riverside Church on Riverside Drive and 122nd Street.

Other buildings of architectural interest in New York City include the many narrow brownstone houses that line side streets in Manhattan and Brooklyn. Most of these houses were built in the late 1800's as single-family homes. Today, many of them have been divided into apartments.

Libraries. New York City has three public library systems. The New York Public Library system serves Manhattan, the Bronx, and Staten Island. The Brooklyn Public Library serves Brooklyn, and the Queens Borough Public Library serves Queens. Altogether, the three systems have nearly 200 branch libraries.

The New York Public Library system has 80 of the branches—more than any other city public library in the United States. The library's Central Research Building on Fifth Avenue at 42nd Street is a Manhattan landmark.

In addition to the public library systems, New York City has more than 1,000 libraries operated by schools, colleges, and private organizations. Many of these libraries are highly specialized. For example, the Pierpont Morgan Library has rare books and manuscripts, and the Dag Hammarskjöld Library at the United Nations...
specializes in books dealing with international affairs and world peace.

Nearly all museums in New York have an associated library. The most important of these libraries include the Metropolitan Museum Art Reference Library, the Frick Art Reference Library, and the Museum of Natural History Library.

**Museums.** New York City has many kinds of museums. The Metropolitan Museum of Art on Fifth Avenue at 82nd Street is the largest art museum in the United States. It has more than 2 million works of art. These works represent nearly every culture of the last 5,000 years. The museum occupies four city blocks, yet it has space to display only part of its huge collection at one time. The Cloisters, a branch of the Metropolitan Museum, is devoted to European art of the Middle Ages. The building is designed like a medieval monastery. The Cloisters stands in Fort Tryon Park at the northern tip of Manhattan.

Several New York City museums specialize in modern art, such as the Museum of Modern Art, located temporarily in Queens, the Whitney Museum of American Art on Madison Avenue and 75th Street, and the Guggenheim Museum on Fifth Avenue at 89th Street. The Guggenheim is in an unusual circular building designed by the famous American architect Frank Lloyd Wright. The Frick Collection on 70th Street at Fifth Avenue has a notable collection of art that dates from the 1300's through the 1800's. The museum occupies one of Manhattan's few remaining mansions.

The American Museum of Natural History stands at 79th Street and Central Park West. It has the largest amount of exhibition space of any natural history museum in the world. The American Museum's exhibits include lifelike models of animals shown in reproductions of their natural surroundings.

New York City also has several historical museums. These museums include the Museum of the City of New York on Fifth Avenue at 103rd Street.

**Parks.** New York has more parks, playgrounds, beaches, and other recreational areas than any other city in the United States. Many parts of New York are so crowded, however, that children must still play in the city streets.

Central Park, in the middle of Manhattan, is the best known of the city's more than 100 parks. This vast recreational site is 2 ½ miles (4 kilometers) long and ½ mile (0.8 kilometer) wide and has athletic fields, gardens, a lake, playgrounds, and wooded areas. Central Park includes the Mall, where outdoor concerts and other events are held, and the Ramble, an enclosed bird sanctuary.

The Gateway National Recreation Area forms a 26,579-acre (10,756-hectare) park. It covers shorelines and islands of Queens and Brooklyn, as well as part of the Staten Island shore.

Other large parks in New York City include Bronx and Van Cortlandt parks in the Bronx, Prospect Park in Brooklyn, and Flushing Meadow-Corona Park in Queens. In many parts of the city, small parks and playgrounds have been developed on any open land that was available, including single empty lots.

New York City has several zoos and botanical gardens. Central Park in Manhattan contains a zoo. The Bronx Zoo (officially the International Wildlife Conservation Park) in Bronx Park has one of the largest collections of animals of any zoo in the United States. Bronx Park also includes the New York Botanical Garden, which features plants from most parts of the world. In addition, Brooklyn and Queens have outstanding botanical gardens.

In addition, the city has two National Football League teams. The New York Jets of the American Conference and the New York Giants of the National Conference both play in Giants Stadium in nearby East Rutherford, New Jersey.

New York City also has two professional hockey teams—the New York Islanders and New York Rangers of the National Hockey League—and a professional basketball team—the New York Knickerbockers of the National Basketball Association. The Islanders play in the Nassau County Coliseum in Uniondale, New York. The Knickerbockers and Rangers play in New York City's Madison Square Garden.

**A visitor's guide**

Each year, about 17 million tourists and delegates to conventions and trade shows visit New York City. To accommodate all these visitors, New York has hundreds of hotels, motels, and rooming houses, and thousands of restaurants. Some of the city's hotels rank among the world's most luxurious. Many restaurants specialize in a certain type of cooking, such as Chinese, French, German, or Italian. In fact, no other city in the world has so many kinds of restaurants as New York.

Following are descriptions of some of New York City's many interesting places to visit. Other places of interest in the city are discussed and pictured earlier in this article.

**Empire State Building** on Fifth Avenue between 33rd Street and 34th Street is a 102-story New York City landmark. Public observation decks on the 86th and 102nd floors of the Empire State Building offer visitors spectacular views of the city.

**Financial District** is centered on Wall and Broad streets near the southern tip of Manhattan. Many banks, brokerage houses, and stock exchanges are in the district. Tours are given of the New York Stock Exchange, a corner of Wall and Broad streets.

**Greenwich Village** lies south of 14th Street and west of Broadway. Many actors, artists, musicians, and other people in the arts live in the area and in the SoHo area to the south. The Village and SoHo have several small theaters and many interesting shops and art galleries.

**Museum of Modern Art** displays modern paintings, sculptures, films, photographs, and other works of art. It is temporarily located in Queens while its West 53rd Street site is being expanded and renovated.

**Rockefeller Center** on Fifth Avenue between 48th and 51st streets includes the sunken Plaza, used for outdoor dining in summer and ice skating in winter; the 70-story RCA Building, which has a public observation room; Radio City Music Hall, a 5,900-seat theater featuring films and stage shows; and the studios of the National Broadcasting Company (NBC). Tours are given of the NBC studios and of the entire center.
St. Patrick's Cathedral is located at Fifth Avenue and 50th Street, across from Rockefeller Center. It is the seat of the Roman Catholic Archdiocese of New York. St. Patrick's Cathedral is one of the finest examples of Gothic Revival architecture in the United States. See Saint Patrick's Cathedral.

Statue of Liberty on Liberty Island in New York Harbor is the world-famous symbol of American freedom. Boats carry visitors to the island from Battery Park at the southern tip of Manhattan. See Statue of Liberty.

Government

New York City's government is presently organized under a charter that was adopted in 1961 and that became effective in 1963. The government of New York is more centralized than that of most other cities in the United States. In New York, the central government is responsible for public education, correctional institutions, libraries, public safety, recreational facilities, sanitation, water supply, and welfare services. In most of the
other cities in the United States, however, at least some of these services are provided by separate government units.

Until mid-1990, the New York City legislature consisted of a City Council and the Board of Estimate. In 1989, however, the Supreme Court of the United States declared that the composition of the Board of Estimate was unconstitutional because smaller boroughs had as many votes as larger boroughs. In November 1989, residents of New York City approved a plan to revise their city charter, which included abolishing the Board of Estimate. This revision was approved by the United States Department of Justice in December 1989. A number of changes went into effect immediately. The Board of Estimate was eliminated in September 1990.

New York City's government is headed by a mayor and a City Council. The mayor is the chief executive of New York City. The mayor is elected to a four-year term and is responsible for the administration of city government. The heads of about 50 city departments are appointed by the mayor. The mayor also may appoint one or more deputy mayors as assistants.

The City Council consists of a council president and representatives from each of the city's 51 districts. Council members and the president are elected in citywide elections and serve four-year terms. The president presides over meetings but may vote only in the event of a tie. The council also elects one of its members to the position of council speaker and majority leader. The council may pass laws and must approve the city's budget. It also has jurisdiction over most land use issues.

New York City has five boroughs. Each borough elects a borough president to a four-year term. The borough presidents advise the mayor on issues of interest to their boroughs. They also may serve on special city committees.

New York City has an annual budget of about $29 billion. The city gets part of its income from about 20 different taxes, including an income tax, real estate tax, and sales tax. The real estate tax provides the most tax income. But the total tax income is far from enough to meet the city's expenses. The city gets additional money from the state and federal governments.

The Democratic Party has long been the most powerful political party in New York City. It has more than three times as many members as the Republican Party and usually controls between 75 and 85 percent of the city's elective offices. Neither the Democratic nor the Republican party in New York City has a strong citywide organization. Both political parties have separate organizations in each of the five boroughs.

Two minor political parties, the Liberal and the Conservative parties, also influence New York City politics. Both of these parties have affected city elections chiefly by supporting candidates from one of the two major parties.

History

The earliest people known to have lived in the New York City area were American Indians. Several tribes of the Algonquian family of Indians lived peacefully on the shores of New York Harbor and along the banks of the Hudson and East rivers. The Indians lived in small villages of bark houses. They fished, hunted, raised crops, and trapped animals. They traveled the area's waterways in sturdy canoes.

Exploration. The first European to enter New York Harbor was probably Giovanni da Verrazzano, an Italian explorer employed by the king of France. Verrazzano and his crew landed on Staten Island in 1524, while exploring the North American coast.

Other explorers visited the New York City region after Verrazzano. But none of these explorers reported seeing the island the Indians called Man-a-hat-ta (Island of the Hills). Finally, in 1609, Henry Hudson reached Manhattan and then sailed up the river that now bears his name.

City Hall, completed in 1811, is one of New York City's architectural landmarks. The building is part of the Municipal Civic Center and is surrounded by City Hall Park and by other city government buildings. The mayor and the mayor's staff have their offices in City Hall.
Hudson was a citizen of England who was exploring for the Dutch, and so the Netherlands claimed the territory he had found. The region was later named New Netherland.

**Settlement.** In 1613, the Dutch trader and explorer Adriaen Block and his crew became the first Europeans to live on Manhattan Island. They built several huts and spent the winter near the southern tip of the island after their ship was destroyed by fire. Adriaen and his crew built a new ship and left Manhattan Island in the spring of 1614.

In 1624, the Dutch West India Company, a trading and colonizing firm, sent settlers to Manhattan. In 1625, the settlers laid out a town and built a fort called Fort Amsterdam at the island’s southern tip. The next year, the governor (or director-general) of New Netherland, Peter Minuit, bought the island from the Indians for goods worth 60 Dutch guilders, the equivalent of about $24.

Soon after Fort Amsterdam was built, the entire settlement was named New Amsterdam. The colony grew slowly at first because the governors sent by the Dutch were poor administrators. But in 1647, Peter Stuyvesant became governor, and under his administration the town began to prosper rapidly.

About 1,000 people lived in New Amsterdam during the 1650’s. Their houses stood along narrow dirt lanes. In 1653, the colonists built a wall along the northern edge of town because they feared attacks by Indians or by white enemies. But the wall fell down within a few years. Later, the colonists laid out a road in its place. The road became known as Wall Street.

While New Amsterdam was being established on Manhattan Island, colonists were also arriving in what is now the Bronx, Brooklyn, and Queens. Jonas Bronck, a Dutch citizen from Scandinavia, after whom the Bronx is named, became the first European settler in that area. Bronck set up a 500-acre (200-hectare) farm in 1641 and was soon followed by other settlers. Dutch and English colonists established small villages in Brooklyn and Queens. Staten Island developed more slowly than the other areas partly because settlers there often had trouble with Indians.

**English rule.** The Netherlands and England fought three naval wars between 1632 and 1674. In 1664, English warships sailed into New York Harbor and forced Peter Stuyvesant to surrender New Amsterdam. The Dutch regained the colony a few years later but then gave it to England under the terms of a peace treaty. The English renamed the colony New York.

New York grew quickly under English rule. By 1700, its population reached about 7,000, and buildings filled lower Manhattan. The town’s first newspaper, the New York Gazette, appeared in 1725. King’s College, now Columbia University, was founded in 1754.

New York City played an important role in the American Colonies’ fight for freedom from Britain. In 1765, the Stamp Act Congress met in New York to protest unfair taxes. In 1770, New Yorkers clashed with British soldiers, and one man was killed in the fighting. Soon after the Revolutionary War in America began in 1775, American forces took possession of the city. But the British regained New York City after the Battle of Long Island in 1776. They held the city until the Revolutionary War ended in 1783.

In January 1785, New York City became the temporary capital of the United States. The Congress of the United States met in the city until August 1790. George Washington was inaugurated in New York City as the nation’s first president in April 1789.

**The growing city.** During the early years of the United States, Philadelphia and Boston were larger and more prosperous than New York. But New York’s economy and population expanded rapidly. The city took advantage of its excellent natural harbor to increase its trade with other East Coast ports and with foreign countries. European immigrants began to pour into the city. By 1800, New York had about 60,000 people, more than any other city in the country.

New York’s growth continued during the early 1800’s. In 1811, city officials, planning for further expansion, decided that all newly built Manhattan streets should run in straight lines. That decision resulted in the regular pattern of cross streets north of what is now Greenwich Village.

The Erie Canal opened in upstate New York in 1825. The canal provided an important link in an all-water route between New York City and the rapidly developing Midwestern States (see Erie Canal). An increasing number of banks, insurance companies, and investment firms added to the city’s economic growth.

New York’s neighboring communities also grew quickly during the early 1800’s. Brooklyn, the most im-
important of these communities, was incorporated as a village in 1816 with 3,300 residents. By the time it became a city in 1834, it had about 24,000 people.

During the 1800's, thousands of European immigrants arrived in New York City every year. Until about 1890, most of them came from Germany, Ireland, and other countries of northern and western Europe. After about 1890, most immigrants came from southern and eastern European countries. Many immigrants had difficulty adjusting to the city. They lived in crowded slums and had trouble finding jobs.

Politicians, especially members of the Democratic Party organization in Manhattan called Tammany Hall, offered jobs, gifts, and advice to immigrants. In return, the immigrants voted to keep Tammany Hall in power. But the politicians actually did little to solve the immigrants' most important problems, such as the need for better housing, education, and medical care. In 1871, Tammany boss William M. Tweed and some of his followers were arrested and charged with cheating the city out of several million dollars. The Tweed Ring, as his group was called, was driven from public life. But the Tammany organization soon regained power. See Tammany, Society of.

Formation of Greater New York. In 1883, engineers completed the Brooklyn Bridge, which provided the first direct link between Manhattan and Brooklyn. In 1889, Brooklyn and several communities in what became the Bronx, Queens, and Staten Island were united with Manhattan to form what was called Greater New York. The sprawling new city had more than 3 million residents. Nearly 2 million of the people lived in Manhattan. However, during the early 1900's, subways and bridges were constructed to provide convenient transportation between Manhattan and the other boroughs. The city's people then began to spread out. As the populations of the other boroughs grew, the population of Manhattan decreased.

But Manhattan remained the largest and most powerful borough of Greater New York, and so its Tammany Hall organization continued to control city politics. Occasionally, voters became angered enough by the illegal activities of Tammany leaders to elect mayors who promised reform. But none of these reform mayors lasted more than one term—until Fiorello La Guardia became mayor in 1934. La Guardia, an honest and outspoken reformer, served from 1934 to 1945. Since his administration, no political organization has been able to control New York politics.

Recent developments. Since the 1940's, New York City, like other communities, has been troubled by many problems. The severity of the problems began increasing during the early 1960's. Air and water pollution harmed New York City's environment. Highways and mass transportation systems became overcrowded and outdated. Housing shortages increased. Racial conflict worsened.

New York City has also faced a series of damaging strikes by public employees. In 1966, transit workers struck for 12 days, halting all subway and bus service. In 1968, striking sanitation workers let garbage pile up on city streets for 9 days. In 1971, police officers refused to go on patrols for 6 days. These and other strikes involved disputes over such matters as wages, benefits, and working conditions.

New York City experienced a financial crisis in 1975, when the city's government lacked enough money to pay all its bills for the year. The New York state legislature helped ease the situation by establishing the Municipal Assistance Corporation, which lent the city some money. The federal government also provided funds for the city. To help pay its expenses during the late 1970's,

Thousands of immigrants arrived in New York City every year during the 1800's. Before entering the city, many immigrants had to pass through the immigration station on Ellis Island. The island is now part of the Statue of Liberty National Monument.
New York City's Theater District as it is today. Much of the area has been redeveloped, but it remains the center of the Theater District.

New York City increased city taxes, eliminated thousands of city government jobs, and reduced city services. In the 1980s, the city's economic situation improved.

In 1989, the Supreme Court of the United States declared the Board of Estimate of New York City unconstitutional. See the Government section of this article for details.

In February 1993, a powerful bomb exploded in a parking garage of the World Trade Center. The blast killed 6 people and injured more than 1,000. It caused more than $300 million in damage to the Trade Center.

In 1993, the Supreme Court of the United States declared the Board of Estimate of New York City unconstitutional. See the Government section of this article for details.

A rise in the city's spirit took place about the same time Giuliani became mayor. About a million new immigrants and a booming New York-based stock market helped to invigorate the city's economy. New York City's crime rate dropped, and real estate prices soared. Neighborhood environmental efforts helped clean the city's air and the Hudson River.

On Sept. 11, 2001, terrorists in hijacked commercial airplanes crashed the planes into the twin 110-story towers of the World Trade Center. In related incidents that day, a hijacked plane crashed into the Pentagon Building, just outside Washington, D.C., and another hijacked plane crashed into the World Trade Center.

A financial crisis hit New York City in 1975 and caused great concern for the city's future. A rally in Times Square, shown here, supported the use of federal aid to help the city.

The collapse of a World Trade Center tower on Sept. 11, 2001, sent people fleeing. Terrorists sent two hijacked jetliners crashing into the center's twin towers, destroying both buildings.
plane crashed in Pennsylvania. The Trade Center towers collapsed to the ground. Part of the Pentagon was destroyed. About 3,000 people were killed. The terrorist attack was the worst in U.S. history.

New York Public Library

New York Public Library is one of the most extensive public library systems in the United States. It was founded in 1895. The library operates four research centers that depend heavily on private contributions: the Humanities, Social Sciences and Special Collections; the Schomburg Center for Research in Black Culture; the New York Public Library for the Performing Arts; and the Science, Industry and Business Library Center. Public funds from New York City support a system of 82 branch libraries in the boroughs of Manhattan, the Bronx, and Staten Island. The library's landmark Central Research Library, located at Fifth Avenue and 42nd Street, was designed in 1904 by American architects Thomas Hastings and John M. Carrere. The city has two other public li-
brary systems, the Brooklyn Public Library and the Queens Borough Public Library.

The research libraries collectively contain about 36 million items, including books, manuscripts, pictures, maps, and reels of film and microfilm. The branch libraries have approximately 10 million items, including about 300,000 books in braille and on cassette tape.

New York State. See New York.

New York State Barge Canal System connects the state's principal natural waterways. The toll-free canal system and its connecting waterways extend 800 miles (1,300 kilometers) from Lake Champlain and the Hudson River to Lake Erie and Lake Ontario. The canal system proper is 524 miles (843 kilometers) long.

The system consists of four canals—the Erie, the Champlain, the Oswego, and the Cayuga and Seneca. The 348-mile (560-kilometer) Erie Canal connects Tonawanda on the Niagara River with Troy and Albany on the Hudson River. The Champlain Canal, between Whitehall on Lake Champlain and Waterford near Troy, is 60 miles (97 kilometers) long. The 24-mile (39-kilometer) Oswego Canal links Oswego on Lake Ontario and Three Rivers on the Erie Canal. The Cayuga and Seneca Canals include passages through Cayuga and Seneca lakes. It extends 92 miles (148 kilometers) from the Erie Canal through Montezuma Swamp and southward to Ithaca, Watkins Glen, and Montour Falls.

The New York State Legislature authorized construction of the canal system in 1803. It did so under strong pressure from merchants and other business people who did not want the railroads to have total control of transportation across the state. The system was opened in 1817. It has 57 locks, each 300 feet (91 meters) long and 43 (13.3 meters) wide. It has a channel depth of 14 feet (4.3 meters) from Waterford to Oswego and 12 feet (3.7 meters) on all its other canals.

The locks can handle barges carrying over 3,500 tons (3,180 metric tons) of cargo. A vessel can pass through a lock in 20 minutes. About 210,000 tons (190,000 metric tons) of cargo and thousands of pleasure boats move through the system each year. Since the mid-1900's, the use of the system for the shipment of cargo has decreased greatly. At the same time, its use for pleasure boats has increased sharply.

New York Stock Exchange is the oldest and largest stock exchange in the United States. Brokers on the exchange buy and sell shares of stock in most of the largest U.S. corporations. They also trade stock in many firms headquartered outside the United States. Prices are set largely by supply and demand on a central trading floor. The New York Stock Exchange stands at the corner of Broad and Wall streets in New York City.

The New York Stock Exchange, often called the NYSE, sets standards for those who want to trade there. Brokers must pass a written examination. They also must register with the Securities and Exchange Commission (SEC). The SEC is a U.S. government agency that administers and enforces federal laws governing the purchase and sale of stocks and bonds.

The New York Stock Exchange traces its roots to 1792, when a group of New York City stock dealers and traders agreed to funnel business to one another. They called their arrangement the Buttonwood Agreement, after the buttonwood tree under which they met. New York City brokers established a formal organization, the New York Stock and Exchange Board, in 1817. In 1863, the group changed its name to the New York Stock Exchange. New York University, in New York City, is a privately endowed nonsectarian coeducational institution. It is the largest privately supported university in the United States. The university offers over 2,500 courses of study in many fields. It employs over 5,000 faculty members.

Ten major divisions of the university are located around Washington Square Park: the College of Arts and Science; the Stern School of Business undergraduate division; the School of Continuing Education; Tisch School of the Arts; the School of Education, Health, Nursing, and Arts Professions; the School of Social Work; the Gallatin Division, which lets students design their own courses of study; the Graduate School of Arts and Science; the graduate division of the Stern School of Business; the Wagner Graduate School of Public Service; and the School of Law.

The New York University Medical Center has a program of medical education, research, and patient care. The College of Dentistry offers instruction and conducts dental research as well as several clinics. The Institute of Fine Arts specializes in the history of art, archaeology, conservation, and the technology of works of art. The Courant Institute of Mathematical Sciences is an international center for research and teaching in such areas as mathematics, applied mathematics, and computer science. The university was founded in 1831.

The New York State Barge Canal System consists of the Erie Canal and three other canals. The system connects the principal natural waterways of New York and provides the shortest all-water route between the Atlantic Ocean and the Great Lakes.
New Zealand

New Zealand is an island country in the southwest Pacific Ocean. It lies about 1,000 miles (1,600 kilometers) southeast of Australia. New Zealand consists of two main islands—the North Island and the South Island—and a number of smaller islands. The country belongs to a large island group called Polynesia. Wellington is the capital of New Zealand, and Auckland is the largest city.

New Zealand was first settled by Polynesians from the eastern Pacific whose descendants are called the Maori. Many scholars think these Polynesians probably arrived about 1,000 years ago. British immigrants began settling in New Zealand during the early 1800's, and the country became part of the British Empire in 1840. Today, it is an independent member of the Commonwealth of Nations, an association of countries that replaced the empire.

New Zealand's current population represents many cultures. They include the Maori and other Polynesian groups; descendants of English, Irish, and other western European colonial settlers; and more recent immigrants from Asia, Africa, and eastern Europe.

New Zealand is a beautiful country of snow-capped mountains, green lowlands, beaches, and many lakes and waterfalls. No place is more than 80 miles (130 kilometers) from the coast, and most places have striking views of mountains or hills.

Government

New Zealand is a constitutional monarchy. Queen Elizabeth II of the United Kingdom is also Queen of New Zealand. She appoints a governor general, recommended by New Zealand's prime minister, to represent her. The governor general's main function is to arrange for the leader of the political party with the most support in Parliament to form a government. The governor general's consent is required before bills can become law, but this requirement is normally a formality. The legislature, prime minister, and Cabinet run the government.

The constitution. New Zealand has no formal written constitution. The country's unwritten constitution is a combination of precedent (tradition) and written material closely modeled on the constitutional practices of the United Kingdom. Written parts of New Zealand's constitution include Magna Carta, a 1215 document that put the king of England under the rule of law, and the

New Zealand, a country in the Pacific Ocean, lies about 1,000 miles (1,600 kilometers) southeast of Australia. New Zealand consists of the North Island, the South Island, and smaller islands.

Habeas Corpus Act of 1679, which protects people from being imprisoned unjustly.

**The legislature.** New Zealand’s Parliament consists of the monarch, represented by the governor general, and an elected House of Representatives, also called the Parliament. The House of Representatives has 120 members. Voters directly elect 69 of these members. Seven of the directly elected seats are reserved for the Maori, though additional Maori candidates can be elected. The rest of the House is chosen on the basis of proportional representation. Under this method, each political party that receives at least 5 percent of the popular vote gets a number of seats determined by the percentage of the vote it receives. A parliamentary election must be held every three years, but may be held sooner. All citizens 18 years of age or older can vote in a general election.

**The prime minister and Cabinet.** The leader of the political party that wins the most seats in a parliamentary election becomes prime minister. The leading party may also form a coalition government with other parties if it does not gain a majority in Parliament.

On the advice of the prime minister, the governor general appoints the Cabinet to run the various government departments. The Cabinet members, called ministers, are members of Parliament. The prime minister and the Cabinet are called the Government. The Government proposes most new legislation in Parliament. If Parliament votes in favor of the bill, it becomes law.

**Political parties.** There are about 30 registered political parties in New Zealand. The largest are the National Party and the Labour Party. There is no clear division between the policies of either party. Traditionally, the Labour Party has favored government control and public regulation of industry, whereas the National Party has favored free enterprise. Since 1984, however, both parties have adopted similar economic policies.

**Local government.** New Zealand has a unitary system of government, in which Parliament has the power to create and authorize local governments. The country has 12 regions, each with a regional council. Local government is further divided into territorial authorities, community boards, and special purpose authorities. The territorial authorities consist of city councils, district councils, and the council for the Chatham Islands.

**Ombudsman** is an official selected by Parliament to investigate complaints by citizens against government departments and related organizations. If an ombudsman believes a complaint is justified, he or she reports it to the department concerned along with any recommendation for action.

**Courts.** New Zealand’s highest court is the Court of Appeal, which hears mainly cases that have been appealed from a lower court. Some decisions of the Court of Appeal, such as those involving large amounts of money, may be appealed to the Privy Council in the United Kingdom. The Privy Council is an honorary panel of advisers to the monarch (see Privy Council).

Below the Court of Appeal in New Zealand are the High Court and district courts. The High Court deals with major crimes, important civil claims, and appeals from lower courts. It also reviews administrative actions. District courts serve specific regions. Justices of the peace and community magistrates hear traffic and minor criminal charges. A number of courts also have special
functions, such as the employment court, family court, youth court, environment court, and Maori Land Court.

**Armed forces** of New Zealand are called the New Zealand Defence Force (NZDF). The NZDF consists of a navy, army, and air force, together with civilian employees. Military service is voluntary.

**Overseas territories.** New Zealand governs two overseas territories. They are Ross Dependency, a part of Antarctica; and Tokelau, an island group northeast of New Zealand. New Zealand formerly governed the Cook Islands and the island of Niue. The Cook Islands became self-governing in 1965 and Niue in 1974. But the people of these islands are still considered citizens of New Zealand, and the country still has some responsibility for the islands' defense and foreign affairs.

**People**

New Zealand has two main ethnic groups, the Maori and whites of European ancestry. The Maori make up about 15 percent of the population and form the country's largest minority group. More than 80 percent of the people are New Zealanders of European ancestry. The number of New Zealanders of other Pacific Island or Asian ancestry is growing. People of non-Maori ancestry are known as Pakeha (pronounced PAH kah hah). Many Pakeha are descended from British colonists who came to the country during the 1800's, and so many New Zealand customs resemble British customs. However, New Zealand has developed its own sense of identity as a country of both British and Polynesian heritage.

New Zealand has two official languages, English and Maori, though English is the most widely used. Other languages spoken include Cook Island Maori, Dutch, Greek, Italian, Niuean, Samoan, and Tongan.

**Way of life**

City life. New Zealand's cities offer a wide range of economic and social opportunities. City dwellers can work in New Zealand's business, communication, manufacturing, and shipping industries. Urban New Zealanders enjoy easy access to the fine arts, education, entertainment, and night life. New Zealand's cities are fairly uncrowded. Some city dwellers live in high-rise apartment buildings, but most own their own homes.

**Rural life** in New Zealand centers mainly around agricultural activities such as raising sheep and cattle and growing fruits, vegetables, and grain. Many people in the northern part of New Zealand's North Island raise dairy cattle. In other parts of North Island and on South Island, beef cattle and sheep are more common. Farmers produce large amounts of apples, kiwi fruit, and other fruits. Vineyards in the southern regions of North Island, the northern regions of South Island, and the eastern regions of both islands grow grapes and produce New Zealand wine.

**Food and drink.** New Zealand's cooking combines British traditions with foods grown in the country. Traditionally, New Zealanders have favored beef, mutton, and venison served as steaks, as sausages, or in meat pies. But vegetarianism is increasing in popularity. New Zealand's coastal waters offer an abundance of seafood. Dairy products such as milk, cheese, and ice cream are important foods. A favorite dish is a sweet meringue dessert called pavlova. Tea, coffee, beer, and wine are popular beverages.

**Recreation.** Sports and outdoor activities are important forms of recreation in New Zealand. New Zealanders enjoy Rugby Union, a form of rugby football generally regarded as the national sport. New Zealand's national Rugby Union football team is called the All Blacks. Cricket is another popular spectator sport. In the summer, New Zealand's mountainous terrain offers mountaineering, hiking, and climbing. In the winter, skiing and other snow sports are popular. New Zealand's
coastal waters attract many boaters and surfers. Horse racing has always been a favored leisure activity.

Fishing and hunting are popular pastimes. Rainbow trout and brown trout abound in New Zealand's lakes and rivers. The North Island's warm coastal waters provide excellent line fishing and spear fishing. Boating offers the additional attraction of deep-sea fishing for marlin, shark, or tuna. The chief game birds for hunters are duck, swan, pheasant, quail, and geese.

Religion. The Anglican Church is the largest religious group in New Zealand. About 18 percent of the people are Anglicans. About 14 percent are Roman Catholics, and about 13 percent are Presbyterians. New Zealand society has become more secular (nonreligious), and a growing number of people have no religious affiliation.

Education. New Zealand has public schools funded by the state and private schools, most of which are church sponsored. All children from the ages of 6 to 16 must attend school, though most children begin at the age of 5. Students who live in isolated areas or who have special physical or psychological needs may receive instruction from The Correspondence School in Wellington. The school also serves adults and pupils who wish to study courses not offered at their local schools.

The country has eight universities. They are Massey University in Palmerston North; Victoria University of Wellington; Lincoln University, near Christchurch; the University of Auckland; Auckland University of Technology; the University of Canterbury in Christchurch; the University of Otago in Dunedin; and the University of Waikato in Hamilton. A number of technical and professional institutions also offer degrees. Three institutions known as wānanga provide technical and university-level programs for Maori students, with an emphasis on Maori culture and language.

Almost all of New Zealand's adult population can read and write. For the country's literacy rate, see Literacy table: Literacy rates for selected countries.

The arts. New Zealand literature first gained widespread attention in the early and middle 1900's. Katherine Mansfield wrote sensitive short stories about her childhood in New Zealand. Sylvia Ashton-Warner is known for her fiction and autobiographical books that draw upon her experiences as a teacher in rural New Zealand. Keri Hulme won fame for her fiction and poetry that deal with the language and culture of the Maori.

Other important New Zealand writers include James K. Baxter, Janet Frame, Ngaio Marsh, and Frank Sargeson.

Important New Zealand painters include Colin McCahon, Rita Angus, and Toss Woollaston. All three were leaders in introducing modern styles to New Zealand art in the 1900's. McCahon painted intense landscapes and religious scenes. Angus created vivid portraits and landscapes in both oil and water color. Woollaston painted landscapes as well as portraits of family and friends. The Maori have maintained a long tradition of folk art, especially carefully detailed woodcarvings and intricate, swirling tattoos. Modern Maori artists have incorporated traditional Maori styles into painting and sculpture.

In music, opera singer Kiri Te Kanawa won international acclaim as one of the finest sopranos of the later 1900's. The New Zealand Symphony Orchestra is internationally recognized. The Royal New Zealand Ballet, established in 1953, is the oldest professional dance company in the country. The New Zealand School of Dance and Te Kura Toi Whakaari o Aotearoa: New Zealand Drama School offer courses in the performing arts. There are many local theater and music groups.

New Zealand has many public museums and art galleries. New Zealand's national museum—Te Papa Tongarewa, Museum of New Zealand—opened in Wellington in 1998. The New Zealand Film Archive collects and preserves a national collection of New Zealand's motion picture history. The New Zealand Historic Places Trust preserves archaeological sites, historic areas and buildings, and sites of special significance to the Maori.

Rugby Union football is widely popular in New Zealand and is regarded as the national sport. The country's national Rugby Union team is the All Blacks, shown here in black uniforms.

### The land

New Zealand lies in the southwest Pacific Ocean. The North Island and the South Island are New Zealand's largest islands. They extend in a curve more than 1,000 miles (1,600 kilometers) long and cover about 99 percent of the country's total area. Cook Strait, which is about 16 miles (26 kilometers) wide at its narrowest point, separates the islands.

**The North Island** can be divided into three main land regions: (1) the Northern Peninsulas and Waikato Basin, (2) the Volcanic Region and Western Hill Country, and (3) the Eastern Hills.

**The Northern Peninsulas and Waikato Basin** occupy most of the northern part of the island. This region has forests, rich lowlands, and undeveloped hill country. In the lower lands, many farmers grow citrus or kiwi fruits or raise dairy cattle. Beef cattle and sheep are raised in the hill country. Long, sandy beaches line the west coast, and many inlets mark the east coast.

**The Volcanic Region and Western Hill Country** cover the western half of the island south of the Northern Peninsulas and Waikato Basin. Much of the region consists of volcanic rock. A large plateau covered with soft, yellow-brown soil made up of crushed *pumice*—the porous stone thrown off by volcanoes—rises along the eastern part of the region in the center of the island.

This region has several active volcanoes, including Mount Tongariro, and the highest peak on the island, 9,175-foot (2,797-meter) Mount Ruapehu. This region also has many hot springs and geysers.

**The Eastern Hills** occupy the eastern and southern parts of North Island. A mountain system runs through the region from East Cape to Cook Strait. The eastern slopes consist mainly of rugged hills. Ranchers use this land for grazing sheep and beef cattle. Lowlands along the east coast are used for growing vegetables and fruits. To the west of the mountains are lowlands and plains. Farmers raise dairy cattle, other livestock, and crops in this region.

**The South Island** has three main regions: (1) the Southern Alps and High Country, (2) the Canterbury Plains, and (3) the Otago Plateaus and Basins.

**The Southern Alps and High Country** cover most of the island. The highest peak in New Zealand, 12,316-foot (3,754-meter) Mount Cook, rises in the Southern Alps. The Maori name for Mount Cook is *Aoraki*, also spelled *Aorangi*, which is usually translated as *cloud piercer*.

---

**Majestic Mount Cook**, New Zealand's highest mountain, soars 12,316 feet (3,754 meters) on the South Island. Mount Cook and hundreds of other peaks attract many mountain climbers.
The Mount Cook region has some of New Zealand’s most spectacular scenery. Glaciers lie on mountain slopes high above thick, green forests. Sparkling lakes nestle in valleys throughout the regions. The western slopes of the Southern Alps and High Country region are forested, rainy, and rugged. The eastern slopes are lower and much less rainy. Along the southwest coast, long inlets of the sea called fiords cut into the land, creating a jagged coastline. Forested mountains border many of the fiords.

The Canterbury Plains lie along the east-central coast of the South Island. They form New Zealand’s largest area of flat or nearly flat land and make up the chief grain-growing region. The plains are laid out in a patchwork of fields on which farmers grow barley, fodder crops, oats, and wheat. The plains are also an important region for raising sheep.

The Otago Plateaus and Basins lie in the southeast corner of the South Island. The region has plains and rolling hills, where crops and livestock are raised.

Other islands. Stewart Island lies about 20 miles (32 kilometers) south of the South Island. Scrubby bushes cover most of the island. Most of the people earn their living by fishing and oyster gathering. The Chatham Islands lie about 530 miles (850 kilometers) east of the South Island. Most Chatham Islanders are Maori. Fishing and sheep farming are their main occupations.

Other islands and island groups are the Antipodes Is.
lands, the Auckland Islands, the Bounty Islands, Campbell Island, the Kermadec Islands, the Snares Islands, Lord Island, and the Three Kings Islands. Of these, only Campbell Island has a permanent population.

Lakes, rivers, and waterfalls. New Zealand has many rivers, lakes, and waterfalls. In the alpine regions of the South Island, mountain snows and glaciers feed many rivers. The North Island has New Zealand’s longest river, the Waikato, flowing 264 miles (425 kilometers). The island also has the largest lake, Lake Taupo, which covers 234 square miles (606 square kilometers) and is a vacation area famous for trout fishing.

On both islands, the rivers rise in the mountains and low down to the sea. Most of the rivers flow swiftly and are difficult to navigate. The Clutha River on the South Island carries the largest volume of water. The rapid low of the rivers makes them important sources of hydroelectric power.

New Zealand has many waterfalls. Sutherland Falls umbles 1,904 feet (580 meters) down a mountain near Milford Sound on the South Island.

Animal life. The islands of New Zealand were isolated for about 80 million years. As a result, the animal life is unique but limited in variety. There are many species of beetles, flies, and moths. The islands have several types of frogs, geckos, and skinks, and an ancient reptile called the tuatara. The only native land mammals are bats, but dolphins, seals, and whales live in the surrounding ocean. There are also many species of coastal and wetland birds. The flightless kiwi lives only in New Zealand. Kiwi has become a nickname for a New Zealander. The kea is a parrot noted for its playfulness.

Settlers introduced many animal species from other lands. The ancestors of the Maori introduced the dog and one type of rat to the islands. Europeans brought many other animals, including deer and rabbits, as well as cattle, pigs, and sheep. Small kangaroos called wallabies and brush-tailed possums came from Australia. The new species have depleted the native species to the extent that many are now severely endangered.

Plant life. About 7,000 years ago, rain forests covered most of what is now New Zealand. In the relatively dry Otago Plains in the south of the South Island, grasses and shrubs flourished. As the climate cooled, plant species sensitive to frost diminished, while more cold-tolerant species thrived, especially in upland areas. Low forests developed on the South Island. On the North Island, broadleaf and cone-bearing trees, such as the kauri, became more widespread. Beech forests grow on the cooler uplands of both islands. Since 1900, people have introduced many foreign trees into New Zealand.

Earthquakes. New Zealand has about 100 earthquakes every year that are strong enough to be felt. The country’s most disastrous earthquake occurred near Tawake Bay in 1931. It killed 256 people and badly damaged the cities of Hastings and Napier.

Climate

The country has a mild, moist climate. New Zealand lies south of the equator, so its seasons are opposite those of the Northern Hemisphere. July is New Zealand’s coldest month, and January and February are the warmest months. The country’s mild climate results from ocean breezes that bring warmth in winter and cool temperatures in summer. Average summer temperatures range from about 59 °F (15 °C) to about 69 °F (20 °C), but summer temperatures occasionally rise above 90 °F (32 °C). Average winter temperatures range from about 35 °F (2 °C) to about 53 °F (12 °C).

Climate regions. On the North Island, the northern tip of the Northland Peninsula is warm and humid all year. The island’s central plateau has hot, sunny weather in summer and sharp frosts with occasional snow in winter. Wellington lies exposed to the frequent gales of Cook Strait. On the South Island, the rainy west contrasts with the drier east. Southern New Zealand is cooler than northern New Zealand.

Rainfall. The mountains chiefly control the distribution of rainfall in New Zealand. Winds from the west carry moisture from the ocean. This moisture falls as rain on the western slopes of the mountain ranges. Almost the entire west coast of the South Island averages more than 80 inches (200 centimeters) of rain a year. Milford Sound, on the South Island, averages about 260 inches (660 centimeters) of rain each year. East of the mountains, the winds lose most of their moisture. Some eastern regions in the country average less than 20 inches (51 centimeters) of rain a year. Snow seldom falls in lowland areas, though some mountain peaks remain snow-capped all year.

Economy

For many years, New Zealand’s economy depended on agriculture. Agriculture remains important, but changing domestic and international conditions have caused a shift in economic activity. Today, the main economic sector is service industries, which employ about 65 percent of the labor force. Service industries include retail trade, restaurants and hotels, finance, transportation, and community and social services. Nearly 25 percent of the labor force works in industry and construction, and about 10 percent work in agriculture.

Manufacturing. New Zealand’s factories manufacture food, wine and beer, machinery, textiles, wood products, clothing, and footwear. These industries tend to be based in the larger commercial centers, especially Auckland. Since the mid-1900’s, manufactured products have become an important export.

Agriculture. New Zealand’s agriculture has centered on raising sheep and cattle to produce mutton, lamb, beef, wool, dairy products, and hides. Meat products are a profitable agricultural export. New Zealand is the world’s largest producer of crossbred wool, a coarse type of wool from a sheep that is a cross of two breeds. Crossbred wool is used mainly in interior textiles, such as carpets, upholstery, bedding, and rugs. The major crops are apples, barley, kiwi fruit, potatoes, and wheat.

Mining. New Zealand contains a wide variety of minerals. The country is probably best known for its gold, but the mining industry also produces iron sand (sand containing iron ore), coal, limestone, and other mineral products.

Forestry. New Zealand’s indigenous native forests grow mainly in the mountain regions, particularly on the west coast of the South Island. Less than 2 percent of New Zealand’s total forest production is harvested from indigenous forests. More than 99 percent of the timber comes from planted forests, mostly the fast-growing species. The country is probably best known for its gold, but the mining industry also produces iron sand (sand containing iron ore), coal, limestone, and other mineral products.
Monterey pine. The logs are manufactured into plywood, wood pulp, veneer, and other wood products.

**Fishing industry.** New Zealand's exclusive economic fishing zone is one of the largest in the world, an area 15 times larger than the country's land mass. More than 1,000 species of marine fish live in these waters. About 10 percent of them have commercial value. Valuable commercial fish include blue grenadier (also called hoki), jack mackerel, snoek (also called barracouta), southern blue whiting, squid, orange roughy, and tuna.

**Energy.** New Zealand is self-sufficient in all forms of energy except oil. Water power provides about two-thirds of the nation's electric power. Underground steam in the North Island's volcanic area has become an increasingly important source of power. The country also produces a considerable quantity of natural gas.

**International trade.** New Zealand's biggest export and import partners are Australia, Japan, and the United States. The country also conducts trade with China, Germany, South Korea, Taiwan, and the United Kingdom. New Zealand's leading exports are milk powder. Other important exports are aluminum, butter and cheese, fish, fruit and nuts, iron and steel, leather, machinery, meat, mineral fuels, paper, textiles, wood and wood products, and wool. The major imports include machinery, petroleum, plastics, textiles and textile articles, and vehicles.

**Transportation.** New Zealand has about 57,000 miles (92,000 kilometers) of streets and roads and about 3 million motor vehicles. The country also has an extensive rail system to carry both passengers and freight.

New Zealand has one of the highest ratios of aircraft to population in the world. Air New Zealand is the major domestic airline. New Zealand's largest international airports are in Auckland, Christchurch, and Wellington. While international air links have helped overcome the country's geographical isolation, New Zealand still relies heavily on sea transport for overseas trade. Auckland, the nation's chief seaport, overlooks a fine natural harbor in the northern part of the North Island.

**Communication** is one of the most rapidly growing sectors of the New Zealand economy. Television New Zealand operates two television channels, and offshore owners operate two others. There are also a number of local television broadcasters. Sky Television, a pay TV network, broadcasts to subscribers. Radio New Zealand Limited operates a radio network. Special broadcasts promote the Maori language and culture. New Zealand also has privately owned radio stations.

New Zealand has about 30 daily newspapers. The majority of the country's daily papers are owned by Independent Newspapers Limited and Wilson and Horton Limited. These two groups account for almost 90 percent of the country's daily newspaper circulation.

**History**

New Zealand's first settlers, the people who became known as the Maori, migrated from the islands of eastern Polynesia. They survived by fishing, hunting, and eventually farming. These people probably had established settlements along the coast by the A.D. 1000's. The Maori did not see themselves as one nation. Instead, they considered themselves members of their hapu (sub-tribe) and iwi (tribe). These groups jealously defended their territories. Wars among them were common.

**Early European contact.** In 1642, the Dutch explorer Abel Janszoon Tasman became the first European to sight New Zealand. The Maori attacked his boats, and Tasman left without going ashore. In 1769, the British explorer James Cook landed on New Zealand and claimed it for Britain (now the United Kingdom). Although Cook was cautious, he and his crew also had several violent clashes with Maori groups.

In the 1790's and early 1800's, the seals and whales in New Zealand's coastal waters attracted many American, Australian, and European hunters. Traders also came to buy flax and kauri timber from the Maori. Christian missionary groups targeted the Maori as possible converts. By the 1830's, these groups had begun to settle New Zealand.
Zealand. These settlers heavily relied on Maori tribes. Before 1840, no legal government had authority over the settlers and traders who came to New Zealand. Warfare between Maori groups and disputes between missionary and trading settlements were common. In 1835, a group of Maori leaders called the Confederation of Chiefs of the United Tribes of New Zealand signed a declaration proclaiming the country's independence. The declaration requested the British monarch to act as the country's protector.

**European colonization.** Reports of lawless conditions and fear of competition from French and American settlers led the United Kingdom to declare New Zealand a colony. In 1840, the British negotiated the Treaty of Waitangi with the Maori. About 500 Maori chiefs eventually signed the treaty. The Treaty of Waitangi was written in English and then translated into Maori. Problems with the translation of some important words have led to disputes over which rights the Maori kept and which they signed away. For example, in English the treaty proposed that the Maori hand over their sovereignty—that is, their right to rule themselves—in exchange for recognition of their ownership of the land and the right to be protected as British subjects. But in the Maori translation, the words used for sovereignty and ownership could be understood as giving the British limited powers to govern, rather than full sovereignty.

In the United Kingdom, the British colonial organizer Edward Gibbon Wakefield created the New Zealand Company. The company established settlements at Wellington and Wanganui in 1840, New Plymouth in 1841, and Nelson in 1842. Other groups founded settlements at Dunedin in 1848 and Christchurch in 1850. The South Island began to prosper soon after the British claimed New Zealand as a colony. The island's rich grasslands provided good grazing for sheep imported from Australia, and soon the settlers began exporting wool. In 1861, prospectors discovered gold in Otago. Immigrants poured into the country, hoping to strike it rich. Few miners were successful, but many stayed to become farmers.

**The New Zealand Wars.** As the colonists' demand for Maori land grew, disputes over land ownership became more common and more violent. War broke out in 1860 when a group of Maori disputed the government's purchase of tribal land in the Taranaki region. Government forces seized a Maori fortification built on the disputed land near Waitara. The initial fighting in the Waitara region lasted about a year.

In July 1863, the British governor Sir George Grey ordered the invasion of the Waikato district, a Maori-occupied region on the North Island's western side. Grey had heard rumors that the Waikato Maori forces intended to attack Auckland. He was supported by the settlers who wanted to open up the Waikato's fertile grazing lands to British settlement. The wars continued until 1872.

In 1865, the colonial government created an agency called the Native Land Court to establish individual titles to land. The court defied the traditional Maori belief that land belonged to the entire tribe, not to individuals. By the end of the 1800s, settlers had taken most Maori land. The Maori were forced to withdraw into the harshest and most isolated regions of the country.

**Depression and social reform.** The expense of fighting the Maori, along with shrinking profits from South Island gold mines, took a severe toll on New Zealand's economy. Heavy government borrowing to support colonization and development projects also weakened the economy. In the late 1870s, the country entered an economic depression that lasted until the 1890s. In 1890, the Liberal Party won control of the government and remained in power for 21 years.

The Liberal Party represented the first stable nationwide political party in New Zealand's history. The party, under the leadership of Richard John Seddon from 1893 to 1906, carried out an extensive program of social reform. In 1893, New Zealand became the first country to give women full voting rights.

**Dominion status.** In the early 1900s, New Zealanders began to develop a sense of national identity. In 1907, the United Kingdom granted New Zealand's request to become a dominion, a self-governing country within the British Empire. New refrigeration methods developed in the late 1800s contributed to New Zealand's growing prosperity. These methods made it possible to export large quantities of butter, cheese, and meat.

During World War I (1914-1918), New Zealand sent about 100,000 troops to Europe to fight with the Allies against Germany. These soldiers suffered heavy casualties, with about 1 in 7 killed.

The **Great Depression.** New Zealand was hard-hit by the worldwide Great Depression that began in the late 1920s. Unemployment and desperate living conditions led to rioting against the government in the major cities. In 1935, the people elected a Labour Party government. The party increased public works projects, such as railway and road construction and forest planting, to put men to work. In 1938, the government set up a social security program that included health care for all citizens and special benefits for the aged, children, and widows.

**World War II.** In 1939, New Zealand followed the United Kingdom in declaring war on Germany. New Zealand troops fought beside British troops in Europe and the Middle East. When Japan entered the war in 1941, New Zealand began to fear a Japanese invasion. As British power declined in the Pacific, New Zealand in-

creasely relied on the United States. New Zealand fought beside the United States in the Pacific Islands.

During the war, New Zealand's domestic economy boomed. Manufacturing and farm production rose, and wages and prices stabilized. By the war's end in 1945, the country had climbed out of the Great Depression. The mid-1900's brought many years of prosperity.

**International tensions** developed between New Zealand and some of its overseas allies in the 1980's. In 1981, a tour by a South African rugby team caused controversy as many New Zealanders protested South Africa's policy of apartheid/racial segregation.

In 1984, Labour Party Prime Minister David Lange announced that New Zealand would ban ships carrying nuclear weapons or powered by nuclear reactors from entering its ports. This ban brought New Zealand into disagreement with the United States, a military ally. In 1996, the United States suspended its military duties to New Zealand under the ANZUS mutual defense treaty. The ANZUS treaty had been signed by Australia, New Zealand, and the United States in 1951. This suspension was partially lifted in 1999 to allow U.S. and New Zealand troops to participate in joint United Nations (UN) peacekeeping operations.

New Zealand also strongly opposed France's testing of nuclear weapons in the South Pacific. In 1985, the environmental organization Greenpeace planned to use its ship *Rainbow Warrior* to protest French nuclear tests in the Pacific. But French agents bombed and sank the ship in Auckland Harbour, France apologized for sinking the ship in New Zealand's waters but prevented the agents from serving out their prison terms in New Zealand. In 1996, New Zealand cosponsored a UN resolution to ban nuclear weapons from the Southern Hemisphere.

**Maori-Pakeha relations.** Since the 1840's, the Maori had protested abuses of the Treaty of Waitangi. In 1975, the Maori showed their discontent with a march to Wellington. In 1975, the New Zealand government set up a panel called the Waitangi Tribunal to investigate tribal land claims and suggest possible settlements. The panel consists of half Maori and half Pakeha members appointed by the governor general. In 1993, the government reached a historic settlement with a group of Maori known as the Tainui. The settlement included the return of land, money, and a formal apology. Since then, the government has made settlements with several other Maori groups.

**Political changes.** In 1993, New Zealand adopted a *mixed member proportional system* of electing members of Parliament. In this system, some chairs are reserved for elected legislators, while others are divided among the parties that receive 5 percent or more of the popular vote according to their share of the total votes cast. In the 1996 election, the first held under the new system, no party won an outright majority. The number of seats held by third parties and Maoris increased dramatically. To obtain a majority, the National Party formed a coalition with the New Zealand First Party.

How did the Maori and the English differ in their interpretations of the Treaty of Waitangi?
What are the two largest political parties in New Zealand?
Who were the first people to settle in New Zealand?
What are New Zealand's two overseas territories?

Additional resources

Newark, Delaware (pop. 28,547), is the home of the University of Delaware and a manufacturing and research center. It lies in northern Delaware, about halfway between New York City and Washington, D.C. For the location of Newark, see Delaware (political map).

Newark's products include automobiles, fine book papers, and pharmaceutical goods. Engineers develop electronic components in the city's research facilities. Newark was chartered in 1758. It has a council-manager form of government. Peter W. Rees

Newark, New Jersey (pop. 273,546; met. area pop. 2,032,989), is the largest city in New Jersey and one of the nation's leading centers of transportation. Newark lies on Newark Bay at the mouth of the Passaic River, about 10 miles (16 kilometers) west of New York City. For location, see New Jersey (political map).

In 1666, 30 Puritan families from the Connecticut Colony settled in what is now eastern New Jersey. Developers of the area had offered them religious freedom and inexpensive farmland. The settlers founded a village on the Passaic because the site included a harbor and level, unforested land. They named the village Newark—probably for Newark-on-Trent, the English town where their pastor had entered the ministry. The name may also have originated in the phrase new ark, a reference to the Ark of the Convenant mentioned in the Bible (see Ark of the Covenant).

The city. Newark, the county seat of Essex County, covers about 24 square miles (62 square kilometers). The Newark metropolitan area consists of all of Essex, Morris, Sussex, Union, and Warren counties. Downtown Newark has the city's tallest building, the 34-story National Newark Building. Nearby is the First Presbyterian Church, Newark's oldest house of worship, completed in 1791. The Gateway, a group of office buildings and a hotel, rises in the eastern part of the downtown area. African Americans make up more than half of Newark's population. The city also has many people of Italian, Portuguese, or Puerto Rican descent.

Economy. The production of drugs and chemicals ranks as the leading industrial activity in the city. Newark also manufactures electric equipment, processed food, metal products, and nonelectrical machinery.

Newark International Airport, a major passenger and cargo center, lies at the south end of town. Port Newark, a leading New Jersey port, handles the ships of more than 100 ship companies. It is the largest port in the United States for container ships, which carry cargo in large, separate containers. Passenger and freight railroads and about 240 trucking firms serve the city.

Newark ranks as the nation's third largest insurance center. Only companies in Hartford, Connecticut, and in New York City sell more insurance. Newark is the home of Prudential Insurance Company of America, the largest of its kind in the world. The city also serves as New Jersey's leading center of finance and trade. Newark has one daily newspaper, The Star-Ledger.

Education and cultural life. Newark's public school system includes more than 55 elementary schools and about 10 high schools. The city has about 40 parochial and private schools. Institutions of higher learning include the University of Medicine and Dentistry of New Jersey; the New Jersey Institute of Technology; the Newark campus of Rutgers, the State University of New Jersey; and the Seton Hall University School of Law.

The New Jersey Symphony Orchestra performs in the New Jersey Performing Arts Center. The Opera Theater performs in Newark's Symphony Hall. The Newark Museum features art collections, exhibits of science and industry, and a planetarium. The New Jersey Historical Society has a library and a museum of historic items.

Newark has about 40 parks. The largest one, Branch Brook Park, covers 486 acres (197 hectares) and includes more than 3,500 cherry trees.

Government. Newark has a mayor-council form of government. The voters elect a mayor and nine council
members to serve four-year terms. Property taxes are the city's leading source of revenue.

**History.** Delaware Indians lived in what is now the Newark area before white settlers first arrived in 1666. During the late 1700's, a number of tanners settled in Newark. The area had many hemlock trees, which furnished the bark used in making leather. By the early 1800's, about a third of the labor force worked in shoe-making and other leather industries.

The work of Seth Boyden, a Newark inventor, helped the city grow industrially during the early 1800's. Boyden developed such products as patent leather and an improved kind of cast iron. Advances in transportation also contributed to Newark's industrial growth. For example, the Morris Canal, completed in 1831, linked Newark with coal-mining areas in the Lehigh Valley of Pennsylvania. By 1834, a railroad connected Newark and the Hudson River, which separates New Jersey and New York City. Newark had a population of 19,732 when it was incorporated in 1836.

From 1840 to 1860, many German and Irish immigrants settled in Newark to fill the growing number of industrial jobs. By 1860, the city had 71,941 people. A wave of immigration that began in the late 1880's brought thousands of people from eastern and southern Europe to Newark. In 1910, the city had 347,469 people.

Port Newark opened in 1915, during World War I (1914-1918). Newark's chemical industry, which began in the 1870's, expanded greatly during the war and the 1920's. In 1930, the population reached a peak of 442,337.

During the Great Depression of the 1930's, more than 600 Newark factories closed and many neighborhoods became shabby. During World War II (1939-1945), jobs in defense plants drew thousands of African Americans from the South to Newark. They crowded into the city's run-down areas. Beginning in the 1950's, many middle-income families moved from Newark to the suburbs. By 1960, the city's population had fallen to 405,220.

By the mid-1960's, Newark had a large proportion of poor people. The city lacked money to provide adequate services. Almost half the voters were African Americans, but they had little political power. As a result, racial tensions mounted. In July 1967, five days of rioting shook the African American sections of Newark, causing 26 deaths and more than $10 million in property damage. Blacks had charged that widespread dishonesty existed in the city government. A series of investigations following the riots led to the conviction of Mayor Hugh Addonizio and other politicians for sharing illegal refunds on city contracts.

In 1970, the voters elected Newark's first African American mayor, Kenneth A. Gibson. Gibson had been city engineer. He won reelection three times and served as mayor until 1986.

In 1971, a dispute over working conditions developed between white Newark teachers and the city's board of education. As a result of appointments made by Gibson, the board had a majority of black and Puerto Rican members. The dispute led to an 11-week strike by the teachers, the longest in the history of a major U.S. city. This strike increased racial tension in Newark. The school board has since become an elective body.

During the late 1990's, Newark leaders worked to increase the city's job opportunities and improve its housing. The federal and state governments contributed large amounts of money to help with such problems. Much new construction took place in Newark. A series of urban renewal projects begun in the 1960's resulted in the construction of some factories and office buildings. Newark Airport continued a major expansion program started in 1963. Several new university campuses and seaport expansion projects were completed in the 1970's. Construction of new office buildings took place in the 1980's and 1990's. Robert M. Hordon

For the monthly weather, see New Jersey (Climate).

**Newbery, John** (1713-1767), was an English publisher and bookseller. He is famous in the history of children's literature as the first person to print and sell books for children. He published *A Little Pretty Pocket-Book* (1744) and *Goody-Two-Shoes* (1765) and many other little volumes bound in "flowery gilt," a colorful paper from the Netherlands. Many of his books were reprinted in America between 1749 and 1831.

Newbery's bookshop, The Bible and Sun, was in St. Paul's Churchyard, London. He was the friend and patron of Oliver Goldsmith, Samuel Johnson, and many other literary people of his day. Goldsmith portrayed him in his novel, *The Vicar of Wakefield* (1766). It is believed that Goldsmith wrote some of the quaint penny books published by Newbery. These little books are now highly prized.

Newbery was born in Berkshire. The Newbery Medal, which has been awarded each year since 1922 for the finest children's book written by an American, was named for him (see **Newbery Medal**). Jill P. May

See also Literature for children (The 1700's); Mother Goose.

**Newbery Medal** is an annual award given to the author of the most distinguished contribution to American children's literature published in the preceding year. The award was established and endowed in 1921 by Frederic G. Melcher, chairman of the board of R. R. Bowker Co., publishers of *Library Journal* and *Publishers' Weekly*. He named it for John Newbery, an English publisher and bookseller. Melcher also founded the Caldecott Medal. This award is presented annually to the illustrator of the outstanding children's picture book of the preceding year.

René Chambellan designed the Newbery Medal. It is awarded by the Association for Library Service to Children of the American Library Association.

Critically reviewed by the Association for Library Service to Children

Newcastle (pop. 133,686) is one of the largest cities in the Australian state of New South Wales. Newcastle lies along the southeast coast of Australia (see Australia political map). Newcastle is an important industrial and shipping center. Its major industries include the production of steel and base metals. Many buildings date from the 1800's, including Fort Scratchley, the Custom House, Public School, Police Station, and Railway Station. The city is the home of the University of Newcastle.

Permanent European settlement of Newcastle began in 1804, when convicts were sent there from Sydney. The city served as a place of punishment for prisoners until 1824. Newcastle received the status of a city in 1865.

Alan Fitzgerald

Newcastle upon Tyne (pop. 263,000; met. area pop. 1,087,000) is a commercial and manufacturing center of northern England. The city, usually called Newcastle, was formerly a center for mining coal. The expression "carrying coals to Newcastle" means taking something to a place that has more than it needs. Newcastle lies on the Tyne River, near the North Sea (see England political map). It is named after a castle built about 1080 by a son of William the Conqueror, a king of England.

Coal mining and shipbuilding were the city's chief industries from the 1700's until the 1930's. These industries have been largely replaced by the food processing industry and the manufacture of chemical products and heavy engineering equipment. The city is the home of the University of Newcastle upon Tyne.

M. Trevor Wild

Newcomen, noo KLIHM uhn, Thomas (1663-1729), an English inventor, built the first commercially successful steam engine in 1712. His steam engine was used widely in Europe and throughout Britain's coal-mining regions to remove water from mines. It remained popular for over 60 years until the Scottish engineer James Watt developed a greatly improved steam engine.

Newcomen was born in Dartmouth. While selling metal tools, he learned of the difficulty of pumping water from tin mines. He developed an engine that was driven by air pressure. Water was injected into a large metal cylinder filled with steam, condensing the steam and creating a vacuum. The weight of the atmosphere then pushed a piston to the bottom of the cylinder, pulling up the pumps connected to the piston and raising water. To sell his engines, Newcomen formed a partnership with inventor Thomas Savery, who had a patent on a different device that raised water from mines. Newcomen engines could pump over 3 3/4 million gallons (13.2 million liters) of water a day.

Bruce E. Seely

See also Steam engine (History; picture).
Newfoundland and Labrador

Newfoundland and Labrador, NOO fuhrnd LAND, is Canada's newest province. It became a province in 1949. It includes the island of Newfoundland and the coast of Labrador, a part of the Canadian mainland. St. John's, the capital and largest city of Newfoundland and Labrador, ranks among the oldest communities in North America.

For many years, the province's official name was simply Newfoundland. Canada's Parliament changed the official name to Newfoundland and Labrador in 2001.

Fewer people live in Newfoundland and Labrador than in any other province except Prince Edward Island. Most of the land is rugged, especially along the rocky coast. Thick forests grow along tumbling rivers and around sparkling blue lakes. Barren, rocky ridges rise above the green valleys and surround many brown peat bogs (swamps of decayed plants). Arctic winds and ocean currents chill the land and keep the climate cool. Storms occur frequently. Fog often covers the coast.

Almost all of the province's people live near the sea. Hundreds of villages and fishing settlements nestle in small, sheltered bays along the coast. Some places, too small to appear on maps, have such unusual names as Crow Head, Dragon's Bay, and Juniper Stump.

Most people in Newfoundland and Labrador belong to families that originally came from the United Kingdom and Ireland. The people of the many small, isolated fishing settlements, known as outports, have kept much of the language and customs of their ancestors. But this traditional way of life is being threatened by the decline of the fishing industry and by the rapid extension of modern transportation and communication systems.

The coastal waters of Newfoundland and Labrador have long been one of the world's richest fishing areas. For more than 300 years, fishing fleets from a variety of nations have come to share the bounty of the shallow Grand Banks, southeast of Newfoundland. However, bigger trawlers and more efficient ways of finding and catching fish have led to a drop in the numbers of cod and other fishes. As a result, Canada's government has established restrictions on fishing off Newfoundland.

Mining is an important industry in Newfoundland and Labrador. Offshore oil production became a valuable...
Interesting facts about Newfoundland and Labrador

The first successful transatlantic telegraph cable was completed when the Great Eastern, the steamship laying the cable, landed at Heart's Content on July 27, 1866. The Great Eastern, the largest ship in the world at the time, laid the cable on the ocean floor from Valentia, Ireland, to Newfoundland.

First transatlantic cable

Guglielmo Marconi received the first transatlantic wireless message at St. John's on Dec. 12, 1901. The Morse Code signal he received was a letter s sent from Cornwall, England. The signal was picked up by an aerial attached to a kite.

Sir Humphrey Gilbert, an English explorer, arrived in Newfoundland in August 1583. It is sometimes considered England's oldest possession in North America. However, the United Kingdom did not formally recognize Newfoundland as a colony until 1824.

George Hunter, National Film Board of Canada

Open-pit iron mine on the Labrador Peninsula

mining activity in the late 1990's. Iron ore mining on the Labrador Peninsula is also extremely important.

Manufacturing is also important to the province. Manufacturers use the province's extensive timber resources to produce wood pulp and paper.

Newfoundland and Labrador is the oldest English-speaking region of North America. Viking adventurers established a settlement at L'Anse aux Meadows about A.D. 1000. Sailors from the English port of Bristol probably reached the island of Newfoundland in the late 1400's. In 1497, John Cabot, an Italian explorer in the service of England, sailed through the rich fishing waters near Newfoundland. He brought news of the fishing back to Europe. The fisheries attracted many fishing crews, and some of those people settled on the island. During the 1500's, Basque people of southern France and northern Spain established semipermanent whaling and fishing settlements along the Labrador coast. Although its ships used Newfoundland as a fishing area for many years, the United Kingdom did not recognize Newfoundland as a colony until 1824.

For the relationship of Newfoundland and Labrador to the other provinces, see Canada; Canada, Government of; Canada, History of. See also Labrador.
Symbols of Newfoundland and Labrador
The provincial flag was adopted in 1980. The blue section represents Newfoundland and Labrador's ties to the United Kingdom. The red and gold symbolize hope for the future, with the arrow pointing the way. The coat of arms was granted by King Charles I of England in 1637 and officially adopted as a provincial symbol in 1928. The shield has two lions and two unicorns representing the United Kingdom. The Indians symbolize Newfoundland and Labrador's first inhabitants.

General information
Entered the Dominion: March 31, 1949, the 10th province.
Provincial abbreviation: NF (postal).
Provincial motto: Quaerite Prime Regnum Dei (Seek Ye First the Kingdom of God).
Provincial song: "The Ode to Newfoundland." Words by Sir Cavendish Boyle; music by Sir Hubert Parry.

Land and climate
Area: 136,649 mi² (405,720 km²); the island of Newfoundland, 43,008 mi² (111,390 km²); Labrador, 113,641 mi² (294,330 km²).
Elevation: Highest—Mount Cauvonick (called Mont d'Iberville in Quebec), 5,322 ft (1,622 m) above sea level.
Lowest—sea level.
Coastline: The island of Newfoundland, 7,176 mi. (11,548 km); Labrador, 5,078 mi. (8,172 km).
Record high temperature: 100 °F (38 °C) at Happy Valley-Goose Bay on July 4, 1944.
Record low temperature: -55 °F (-48 °C) at Ashuanipi on Feb. 7, 1950.
Average July temperature: 59 °F (14 °C).
Average January temperature: 19 °F (-7 °C).
Average yearly precipitation: 44 in (111 cm).

Important dates
1583 Sir Humphrey Gilbert landed in Newfoundland and claimed the region for England.
1713 Britain obtained Labrador from France in the Treaty of Paris.
1763 The United Kingdom granted Newfoundland the right to elect a general assembly.
1832
Newfoundland and Labrador

Province of Newfoundland and Labrador

People
Population: 512,930 (2001 census)
Rank among the provinces: 9th
Density: 3 persons per mi² (1 per km²), provinces average 13 per mi² (5 per km²)
Distribution: 38 percent urban, 42 percent rural
Largest cities and towns:
- St. John's: 99,182
- Mount Pearl: 24,964
- Corner Brook: 20,103
- Conception Bay South: 19,772
- Grand Falls-Windsor: 13,340
- Gander: 9,651

Economy
Chief products
- Agriculture: milk, chickens, eggs.
- Forestry: pine, spruce.
- Manufacturing: fish products, paper products.
- Mining: petroleum, iron ore.

Gross domestic product
Value of goods and services produced in 2000, $14,081,000,000.*
Services include community, business, and personal services; finance; government; trade; and transportation and communication. Industry includes construction, manufacturing, mining, and utilities. Agriculture includes agriculture, fishing, and forestry.

*Canadian dollars. Source: Statistics Canada.

Government
Provincial government
Premier: term of up to 5 years
Members of the House of Assembly: 48; terms of up to 5 years.
Federal government
Members of the House of Commons: 7 Senators: 6

Sources of information
For information on tourism in Newfoundland and Labrador, write to Tourism Newfoundland and Labrador, P.O. Box 8730, St. John's, NF A1B 4K2. Tourism Newfoundland and Labrador's Website at www.gov.nl.ca/travel also provides tourist information. The Newfoundland Information Service handles requests for information about economy, government, and history in the province. Write to: Newfoundland Information Service, Communications and Consultation Branch, 10th Floor, East Block, Confederation Building, St. John's, NF A1C 5T7.

Newfoundland appealed to the United Kingdom for financial assistance and became a British dependency.

Construction began on a $950-million hydroelectric plant in Churchill Falls in Labrador.

Newfoundland became the 10th province on March 31.
Newfoundland's name was officially changed to Newfoundland and Labrador.

Population. The 2001 Canadian census reported that Newfoundland and Labrador had 512,930 people. The province’s population had decreased by about 7 percent since the 1996 census, which reported a total of 551,792.

St. John’s, on the Avalon Peninsula, is Newfoundland and Labrador’s capital and largest city. It is the center of the province’s only Census Metropolitan Area as defined by Statistics Canada. For the metropolitan area population, see the Index to the political map of Newfoundland and Labrador. About one-third of the province’s people live in the metropolitan area.

Corner Brook and Mount Pearl are Newfoundland and Labrador’s only other cities. About two-thirds of the province’s people live in communities with populations of more than 1,000 persons. Almost all these settlements lie near the coast. Only approximately 3 of every 100 people in the province live in communities on the coast of Labrador. For more information, see the separate articles on Newfoundland and Labrador cities and towns listed in the Related articles at the end of this article.

Nearly all the people of Newfoundland and Labrador are of British, Irish, French, or Aboriginal (Innu or Inuit) descent. Less than 2 percent of the population was born outside Canada. Most of these people came from the United Kingdom or the United States.

Schools in Newfoundland and Labrador operate under a single school system. Eleven school boards in the province administer the daily operations of the schools. Each school board consists of 15 elected members.

Population density
Over 90 percent of the province’s people live near the coast of the island of Newfoundland. St. John’s is the capital and largest city. The Labrador area has relatively few people.

Newfoundland and Labrador University College

Memorial University of Newfoundland, in St. John's, is Newfoundland and Labrador's only university. The school was founded in 1925 as Memorial University College and began granting degrees in 1950.

E. Otto Miller Services
Newfoundland and Labrador has capes and bays, wooded river valleys, and Arctic tundra that provide some of the most spectacular scenery in North America. The province also offers excellent hunting and fishing, and many vacationers participate in these activities. The towns and villages of Newfoundland and Labrador are rich in folk traditions that were brought from other countries by early settlers and still survive. Many community events and provincewide folk festivals feature these traditions. Newfoundland and Labrador also has many community museums and historic sites that reflect the history and heritage of the people.

Port de Grave on Conception Bay

Places to visit

Following are brief descriptions of some of Newfoundland and Labrador's most interesting places to visit:

Cape St. Mary's Ecological Reserve, on the Avalon Peninsula, is one of the largest nesting sites for gannets in North America. More than 5,000 pairs of these large sea birds arrive at the sanctuary each spring to raise their young on the cliff faces. Cape St. Mary's is also a good place to see whales in summer.

Placentia, on the west coast of the Avalon Peninsula, was established by the French in 1662. It was the scene of several historic battles during the 1700's. Prime Minister Winston Churchill of the United Kingdom and President Franklin D. Roosevelt of the United States drew up the Atlantic Charter on a warship near Placentia in 1941.

Port de Grave, on Conception Bay, is one of the most scenic areas in Newfoundland. It attracts sightseers, artists, and photographers from all over the world.

Witless Bay is a small fishing village 20 miles (32 kilometers) south of St. John's. Just offshore is the Witless Bay Ecological Reserve, the nesting area for hundreds of thousands of puffins and murres, and many other sea birds. The reserve is also a good place to see humpback and minke whales in summer.

National parks and sites. Newfoundland and Labrador has two national parks—Gros Morne and Terra Nova. Gros Morne lies on the west coast, and Terra Nova is on the eastern shore. National historic sites include Castle Hill, near Placentia; Cape Spear, near St. John's; Hawthorne Cottage, in Brigus; L'Anse aux Meadows; Port au Choix, on the Great Northern Peninsula; and Signal Hill, in St. John's. For the features of these parks and sites, see Canada (National park system).

The largest provincial park in Newfoundland and Labrador is Barachois Pond Park near St. George's, in the middle of the towering Long Range Mountains. Sir Richard Squires Memorial Park, located on the Humber River, includes the famous Big Falls. Every spring, Atlantic salmon make spectacular jumps up the falls to reach their spawning (egg-laying) grounds upstream. For information on provincial parks, write to Department of Tourism, Culture, and Recreation, Parks Division, P.O. Box 8700; St. John's, A1B 4J6.
Annual events

January-April
Corner Brook Winter Festival (February); Mount Pearl Frosty Festival (February); Grand Bank Winter Carnival (March); Newfoundland and Labrador Drama Festival held in a different location every year in April.

June-September
St. John's Day in St. John's (weekend nearest June 24); Gros Morne Theatre Festival in Cow Head (June-September); Festival of Folk Song and Dance (July); Stephenville Festival, a theater festival (July); Strawberry Festival in Humber Valley (July); Twillingate's Fish, Fun, and Folk Festival (late July); Trinity Pageant (July and August); St. John's Regatta (first Wednesday in August); Bakeapple Folk Festival in Forteau (August); Newfoundland and Labrador Folk Festival in St. John's (August).
Land regions. Newfoundland and Labrador includes parts of two land regions: (1) the Canadian Shield, and (2) the Appalachian Region.

The Canadian Shield covers about half of Canada, including all of Labrador. It is a rough plateau made up of ancient rocks. In Labrador, the edge of this plateau is cut by valleys and by swift rivers that drain into the Atlantic Ocean. Forests cover more than half of Labrador. Southwestern Labrador has many lakes. It also has rich deposits of iron ore. See Canadian Shield.

The Appalachian Region extends through the eastern part of North America from the island of Newfoundland to Alabama. Lowlands form the eastern edge of the island. To the west, the land gradually rises to a plateau with parts more than 2,000 feet (610 meters) above sea level. In the central part of the island, rocky ridges rise from forested valleys. Lakes, ponds, and bogs dot the area. Three peninsulas—the Great Northern, the Avalon, and the Burin—stick out from the island. The mountainous Great Northern Peninsula points northeastern toward Labrador. Forests cover most of it. The Avalon Peninsula, in the southeast, is the most heavily populated part of the province. About 40 percent of the people live there. To the west, across Placentia Bay, lies the hilly Burin Peninsula.

Rocky ridges rise from forested valleys in the Appalachian Region of the province. This region covers the entire island of Newfoundland and includes many lakes, ponds, and bogs.

Coastline of Newfoundland and Labrador is broken by fiords (long inlets) and many bays. The island of Newfoundland has 7,176 miles (11,548 kilometers) of coastline. Labrador's coastline is 5,078 miles (8,172 kilometers) long. Thousands of small islands with a total coastline of 5,739 miles (9,236 kilometers) dot the coastal waters.

Mountains. The highest point in Newfoundland and Labrador is Mount Caubick. This peak in the Torngat Mountains is part of the boundary between Quebec and Newfoundland and Labrador. In Quebec, it is known as Mont d'Hervelle. It rises 3,522 feet (1,062 meters) above sea level. The Mealy Mountains, in southern Labrador, are over 4,000 feet (1,200 meters) high. On the island of Newfoundland, the chief mountains are the Long Range Mountains. The Lewis Hills have the island's highest elevation—2,672 feet (814 meters) above sea level.

Rivers and lakes. The Churchill River in Labrador is Newfoundland and Labrador's longest river. It rises near the Quebec border and flows 600 miles (966 kilometers) to the Atlantic Ocean. On the island of Newfoundland, the Exploits River flows 153 miles (246 kilometers) northeast from Red Indian Lake into Notre Dame Bay.

Labrador's largest lake is Lake Melville, which covers 1,133 square miles (2,934 square kilometers). The next largest Labrador lakes are Michikamau, Lobstick, and...
Dyke lakes, and Lac Joseph. On the island of Newfoundland, Grand Lake is the largest, followed by Red Indian and Gander lakes. Grand Lake covers 205 square miles (531 square kilometers).

**Plant and animal life.** Forests cover about 87,000 square miles (225,000 square kilometers) of the province. Balsam fir and spruce, the most common trees, supply wood for Newfoundland and Labrador's pulp and paper industry. Other trees include the aspen, birch, larch, pine, and white spruce. Shrubs, lichens, and mosses grow at high elevations. Wildflowers, such as butterworts, Canada mayflowers, goldthreads, Indian pipes, pink lady's-slippers, starflowers, and twinflowers, also grow in the province. The pitcher plant, Newfoundland and Labrador's provincial flower, grows in bog areas.

Many species of fish have flourished in the shallow waters surrounding the island of Newfoundland and extending along the Labrador coast. A major habitat for fish is Grand Banks, an underwater plateau. The main species there include capelin, cod, crab, flounder, herring, lobster, plaice, redfish, and scallops.

About 30 kinds of animals live in the province. They include Arctic hares, bears, beavers, caribou, foxes, lynxes, moose, otters, rabbits, seals, and weasels. Two famous breeds of dogs, the Labrador retriever and the Newfoundland, were developed in the province (see Labrador retriever; Newfoundland dog).

Some birds live in Newfoundland and Labrador all year, but many kinds visit the province. Parmigans and ruffed grouse live in the province. Ducks, geese, and snipes visit every summer. Gulls, loons, murres, puffins, terns, and other sea birds feed in the coastal waters.

**Climate.** The cold Labrador Current and arctic winds keep the province cool (see Labrador Current). But the climate varies greatly between Labrador and Newfoundland.

**Average January temperatures**

The province's winters are much colder on the Labrador mainland than they are on the island of Newfoundland.

**Average July temperatures**

The province generally is cool during summertime. The warmest temperatures are found on the island of Newfoundland.

**Average yearly precipitation**

The island of Newfoundland and the southern mainland receive the most precipitation. The north is the driest section.
Newfoundland and Labrador's goods-producing industries depend on its natural resources. These include ore from Labrador, pulpwod from the island of Newfoundland, fish from the Atlantic Ocean, and oil extracted off the coasts. The province exports its goods to the United States, Europe, Asia, and other markets. Service industries account for the largest part of the province's gross domestic product (GDP)—the total value of goods and services produced in a year. Tourism is a growing part of the economy, and tourist spending contributes significantly to the GDP.

Because of a depletion of fish stocks in the Atlantic Ocean off the coasts of Newfoundland and Labrador, a series of fishing restrictions went into effect beginning in the early 1990's. Restrictions included banning catches of various groundfish (fish that swim close to the ocean floor), in particular cod. Some limited fishing of roundfish has been permitted since the late 1990's, however, shellfish catches dominate the industry.

**Natural resources.** Newfoundland and Labrador has one of the world's largest known iron-ore deposits. A significant deposit of nickel, copper, and cobalt was discovered in 1996. Other minerals include dolomite, gold, gypsum, limestone, pyrophylite, sand and gravel, silver, and slate. Oil production off the eastern coast began in 1997. Natural gas deposits also exist in the area, but have not yet been tapped. The province's large forests are valuable natural resources. Although soil is coarse and rocky in most places, the province contains vast stretches of wilderness and startling geological formations.

**Service industries** account for the largest portion of the province's GDP. The leading group of service industries provides community, business, and personal services. Such services include computer services, education, engineering, food and accommodation, health care, and research. Memorial University in St. John's is one of the world's leading centers of ocean research.

Finance, insurance, and real estate form the second most important service industry in terms of the GDP. St. John's is the province's chief banking center.

Wholesale and retail trade rank third among the service industries. This group is the province's second-leading employer. Trade involves the distribution and sale of goods, especially food products and motor vehicles.

Other service industries in Newfoundland and Labrador include (1) transportation and communication and (2) government services. Ships and trucks transport many manufactured goods to market. Telephone and cable television companies are the leading types of communication companies. Information about transportation and communication also appears later in this section.

Most government activities are centered in St. John's.

**Mining.** Oil production is the province's newest mining industry. Production started from the large offshore Hibernia field in late 1997. Within a few years, oil had become the province's most valuable mined product. Plans for developing other fields are under way.

Iron ore ranks second among Newfoundland and Labrador's mined products. All of the iron ore comes from two mines in Labrador, one at Labrador City and the other at Wabush. The province provides about half of Canada's iron ore. Smaller mines throughout the province produce a variety of minerals, including gold, gypsum, and limestone. The discovery of a significant nickel, copper, and cobalt deposit at Voisey's Bay in

**Economy of Newfoundland and Labrador**

This map shows the economic uses of land in Newfoundland and Labrador and where the leading farm, mineral, and forest products are produced. Industrial centers are shown in red.
Labrador has fueled further exploration.

Manufacturing. Newfoundland and Labrador’s manufactured products have an annual value added by manufacture of about 800 million Canadian dollars. This figure represents the increase in value of raw materials after they become finished products. The province’s leading manufactured goods are newsprint and food and beverage products. Large paper mills in Corner Brook, Grand Falls, and Stephenville are among the province’s main employers. Fish products are the leading food product. Other manufactured products include aerospace equipment, boats, concrete, lumber, petroleum products, and printed materials.

Fishing has traditionally been very important to the economy of Newfoundland and Labrador. Before fishing restrictions were imposed in the early 1990’s, cod was the leading fish catch. Today, such shellfish as crab, lobster, scallops, and shrimp make up the leading catches.

Forestry. Fir and spruce provide much of the timber harvested in Newfoundland and Labrador. Most of the province’s timber is used to make newsprint. The rest is used for lumber and firewood.

Agriculture. Due to the lack of fertile soil, agriculture provides less income in Newfoundland and Labrador than in any other province. The leading farm products are chickens, eggs, and milk. The province’s farmers also raise cattle and hogs and a variety of vegetables.

Electric power and utilities. Hydroelectric plants supply about 95 percent of the electric power produced in the province. The rest comes from plants that burn petroleum. The largest hydroelectric plant lies on the Churchill River in Labrador. Most of the power from this plant is sold to a utility company in Quebec. Other utility companies provide gas and water service.

Transportation. Newfoundland and Labrador lies nearer Europe than any other part of North America except Greenland. This location made the province an important stopping point for airplanes and ships traveling across the Atlantic. But increases in the range of planes and ships have reduced the need for refueling stops. Gander and St. John’s have Newfoundland and Labrador’s busiest airports. National and regional airlines serve the province. Labrador has the province’s only rail line. Trains use this line to transport iron ore from western Labrador to Sept-Iles, Quebec.

Newfoundland and Labrador has about 5,500 miles (9,000 kilometers) of roads. Part of the Trans-Canada Highway runs from St. John’s to Channel-Port aux Basques (see Trans-Canada Highway). The province is constructing a Trans-Labrador Highway to connect different regions of Labrador. A ferry service operates the year around between Channel-Port aux Basques and North Sydney, Nova Scotia, and ferries run between Argentia and North Sydney during the summer months. Freighters sail to St. John’s, Corner Brook, Argentia, and Harbour Grace from Toronto, Montreal, and Halifax.

Communication. Newfoundland and Labrador has about 20 newspapers, 2 of which are dailies. The Telegram, the oldest and largest daily, was established in St. John’s in 1879. About 40 radio stations and 4 television stations serve the province. Cable television systems serve a number of communities. A fiber-optic transmission system across the province provides access to high-quality digital telecommunications.

Government

Lieutenant governor of Newfoundland and Labrador represents the British monarch, Queen Elizabeth II, in her role as queen of Canada. The lieutenant governor is appointed by the governor general in council of Canada. The lieutenant governor is considered the head of state, but the position is largely ceremonial.

Premier of Newfoundland and Labrador is the actual head of the provincial government. Newfoundland and Labrador, like the other provinces and Canada itself, has a parliamentary form of government. The premier is an elected member of the House of Assembly. The person who serves as premier is usually the leader of the majority party in the Assembly. The premier must have the support of a majority of the Assembly.

The premier presides over the Executive Council (cabinet). The council includes ministers appointed by the lieutenant governor on the advice of the premier. Most of the appointees are members of the premier’s party in the House of Assembly. Most ministers direct one or more branches of the government. The council, like the premier, must have the support of the majority of the Assembly. Otherwise, the council must resign, or else its supporters must win a majority of seats in the Assembly in a new general election.

House of Assembly is a one-house legislature. It passes the provincial laws. The Assembly has 48 members, each elected from 1 of 48 Assembly districts. Elections must occur at least once every five years. Usually, the lieutenant governor calls a general election after a shorter period, on the advice of the premier.

Courts in Newfoundland and Labrador include the Supreme Court and its regional judicial centers, as well as the Provincial Court, which has branches throughout the province. The Supreme Court has appeal and trial

Divisions. The appeal division has a chief justice and 6 judges. The trial division consists of a chief justice and 8 judges. The Canadian governor general in council appoints Supreme Court justices. The Executive Council appoints judges to the 12 Provincial Court centers.

Local government. St. John's, Corner Brook, and Mount Pearl, Newfoundland and Labrador's three cities, operate under city acts passed by the provincial legislature. Each of the province's incorporated towns and incorporated communities is governed by an elected council. Town councils have from 5 to 11 members who serve four-year terms.

Revenue. Federal grants, corporation taxes, and personal income taxes account for most of the province's income. Additional funds come from service fees and from sales taxes on gasoline, alcoholic beverages, and other products. The province also collects license fees and royalties on the use of natural resources.

Politics. Newfoundland and Labrador has three major political parties—the Liberals, the Progressive Conservatives, and the New Democrats. The Liberals gained power in 1949 and held it throughout the 1950s and 1960s under the leadership of Premier Joseph R. Smallwood. The Conservatives held power from 1972 to 1989. The Liberals regained power in 1989.

History

Early European exploration. Viking explorers probably were the first white people to live in Newfoundland. In 1961, archaeologists discovered the ruins of a Viking settlement on the northern tip of the island. This settlement was established about A.D. 1000.

English fishing crews from Bristol probably reached Newfoundland in the late 1400s. John Cabot, an Italian explorer in the service of England, may have landed on Newfoundland or Nova Scotia in 1497. Cabot thought he had reached Asia. He brought news of Newfoundland's rich fishing to Europe.

Following Cabot's voyage, hundreds of French, Portuguese, and Spanish fishing fleets visited Newfoundland. Among these fishing crews were Basque whale hunters from southern France and northern Spain. Some Base establishments a base at Red Bay, on the southeast coast of Labrador. At that time, Beothuk Indians lived in Newfoundland. During the 1700s, Micmac Indians set up chiefly along the southern coast of Newfoundland. The Beothuk Indians, who became confined to the interior, were unable to compete successfully for resources against the Europeans and the Micmac. They were also susceptible to the diseases the Europeans brought with them. By 1829, the Beothuk had disappeared.

The Innuit, also known as the Naskapi and Montagnais, have lived in southern and central Labrador for thousands of years. The Innuit, formerly called Eskimos, we lived along the coast of northern Labrador for thousands of years.

Colonization. By the late 1500s, English fishing fleets worked and settled mainly along the southern part of the east coast of Newfoundland. French fishing fleets controlled the north and south coasts. But English, French, Spanish, and Portuguese ships often anchored the same harbor. Each harbor was ruled by a "fishing admiral." This official was the master of the first ship to arrive at the beginning of the fishing season. In 1634, Charles I officially gave authority to the English fishing admirals.

In 1583, the English explorer Sir Humphrey Gilbert arrived in St. John's and claimed Newfoundland as part of his new colony. However, he and his crew were lost at sea on their return voyage to England without having established an actual settlement in Newfoundland. John Guy, a merchant, arrived in 1610 with settlers sent by an English company. Guy formed a colony at Cupids, on Conception Bay. Although people continued to live in Cupids from then on, the colony failed as a commercial venture. In 1621, Sir George Calvert (later Lord Baltimore) established a major colony at Ferryland. In 1629, after an unusually cold winter, Calvert requested a royal grant of land farther south and went on to establish the colony of Maryland in what is now the United States.

In 1637, Charles I granted Newfoundland to Sir David Kirke and other nobles. Kirke set up headquarters at Ferryland but had no authority over the English fishing fleets who came to the island each summer. In 1631, the English government called Kirke back to England. After 1651, the English government discouraged further attempts at colonization in Newfoundland.

War with France. French settlers founded Placentia in 1662. Placentia quickly grew into a fortified colony that threatened the English in Newfoundland. England and France did not quarrel openly until William III became king of England in 1689. William declared war on France, and the French and English colonies in North America, including Newfoundland, became part of the battleground. In 1696 and 1697, the French destroyed all English settlements in Newfoundland. However, the war in Europe went against the French, and in 1713, the Treaty of Utrecht gave all of the island of Newfoundland to the British. French kept only the privilege of using part of the northern and western shore for drying fish. That area became known as the French Shore.

In 1729, the British government began to appoint naval officers as royal governors to rule Newfoundland during the summer—that is, the fishing season. Captain Henry Osborne became the first such "naval governor." Britain now the United Kingdom) obtained nearly all the rest of France's possessions in Canada by the Treaty of Paris, which ended the Seven Years' War in 1763.

France received St-Pierre and Miquelon islands from
Newfoundland and Labrador

Historic Newfoundland and Labrador

Viking explorers were probably the first white people to live on the island of Newfoundland. A Viking settlement on the island dates back to about A.D. 1000.

John Cabot, who sailed for England, may have landed on Newfoundland or Nova Scotia in 1497.

The Labrador Boundary Decision of 1927 rejected Quebec's claims, blue area, left, and defined Newfoundland and Labrador's boundaries clearly, right.

A huge hydroelectric plant at Churchill Falls became fully operational in 1974. The plant, which has 11 generators, is one of the largest power projects in the Western Hemisphere.

Important dates in Newfoundland and Labrador

1497 John Cabot raised the banner of King Henry VII on a "new found land" which may have been the island of Newfoundland or Nova Scotia.
1583 Sir Humphrey Gilbert landed in Newfoundland and claimed the region as part of his new colony.
1637 Charles I granted Newfoundland to Sir David Kirke and his partners.
1662 The French established a garrison at Placentia.
1713 The Treaty of Utrecht gave Newfoundland to Britain (now the United Kingdom).
1729 Captain Henry Osborne became Newfoundland's first naval governor.
1763 In the Treaty of Paris, France surrendered Labrador to Britain.
1832 The United Kingdom granted Newfoundland the right to elect a general assembly.
1855 Newfoundland gained a "responsible government" that was controlled by an elected assembly.
1927 The British Privy Council established the present boundary between Quebec and what is now the province of Newfoundland and Labrador.
1934 The United Kingdom suspended Newfoundland's government, established a Commission of Government, and assumed Newfoundland's debts.
1949 Newfoundland became Canada's 10th province on March 31.
1958 Newfoundland introduced free hospitalization and programs for educational improvements.
2001 Canada's Parliament officially changed Newfoundland's name to Newfoundland and Labrador.
Britain and also regained its right to use the French Shore. France gave up this right in 1904.

After the Treaty of Paris, the British government placed the Labrador coast under the authority of Newfoundland's naval governor. The Labrador coast was placed under Quebec-British rule in 1774 and returned to Newfoundland's control in 1809.

**Representation and independence.** By 1815, about 10,000 people were living in Newfoundland. In 1817, Sir Francis Pickmore became the first governor to remain on the island after the close of the fishing season. Many people wanted a strong local government. Led by William Carson, a Scottish surgeon, the people repeatedly asked Parliament for authority to make their own laws. In 1832, the British government established a legislature for Newfoundland. It consisted of a governor, a council, and a general assembly elected by the people.

Newfoundland's new government was a "representative government" because the legislature could make laws. However, the British Parliament had to approve the laws, and a British governor enforced them. Soon, the assembly began to ask the British government for a "responsible government"—one in which the cabinet was controlled by the assembly and not by the governor.

The British colonies in Canada had been granted this form of government in the 1840's. In 1855, Newfoundland was also allowed to set up such a government.

**Economic growth.** Until the mid-1800's, Newfoundland's economy was based chiefly on the fishing and seal industries. Dried cod, seal oil, and seal skins were major exports of the colony. In the 1860's, mineral exploration began, and by 1888, copper mining had become an important industry in Newfoundland. In the 1890's, an iron ore mine opened on Bell Island. A railroad was constructed across Newfoundland from 1882 to 1896. The colony's first paper mill began operating in Grand Falls in 1909. This industrialization, together with a booming fishing industry, gave Newfoundland a strong economy.

In 1927, the British Privy Council established the present boundary between the coast of Labrador and Quebec. This decision gave Newfoundland (later known as Newfoundland and Labrador) the vast mineral resources of the Knob Lake and Wabush Lake regions.

**Ruine and recovery.** After World War I ended in 1918, Newfoundland's prosperity began to fade, chiefly because of the depression in international trade. In the 1920's, Newfoundland tried to revive its lagging industries and to develop new ones. But by 1930, the Great Depression had struck most of the world. Newfoundland's fish, iron ore, and newspaper markets collapsed. The government sank deeply into debt.

Under Prime Minister Frederick C. Alderdice, Newfoundland appealed to the United Kingdom for financial assistance under a new form of government. In 1934, the United Kingdom suspended Newfoundland's government and established a Commission of Government. This government consisted of a British governor and six other men, three of them Newfoundlanders. Newfoundland became a dependency, and the United Kingdom took over its debts.

Economic recovery came slowly. The government reorganized the civil service, improved education and health facilities, and sponsored research to improve agriculture. Newfoundland's fishing and logging industries got much-needed financial aid.

World War II (1939-1945) gave new life to Newfoundland's economy. The fisheries, factories, and mines once again increased production to fill wartime demands. Canada and the United States built military bases in Newfoundland. People at these bases created new demands for local products.

**Confederation with Canada.** In 1948, Newfoundland voters chose to unite with Canada rather than keep the Commission of Government or return to independent self-government. On March 31, 1949, Newfoundland became the 10th province of Canada. Joseph R. Smallwood, leader of the Liberal Party, was the first premier of the new province. Newfoundland was in sound financial condition at the time of confederation. But a wide gap existed between the standard of living in Newfoundland and many of the other nine provinces.

Through confederation, Newfoundland began to share in federal social security benefits. The province participated in federal programs, including development of trade schools and the construction of more than 500 miles (800 kilometers) of the Trans-Canada Highway.

During the 1960's, Newfoundland expanded its industrial and educational facilities and its production and distribution of electric power. After a boom in mineral production, mining began to rival fishing as a major industry. New mines opened, mostly in Labrador.

By the late 1960's, Newfoundland's rural electrification program had brought electric service to over 100 isolated communities in the province. The principal project in the rural electrification program was a huge hydroelectric plant in Churchill Falls in Labrador. The plant began producing power in 1971, and all of its 11 generators were operating by 1974. The plant is one of the largest hydroelectric projects in the Western Hemisphere.

**Leadership changes.** In the 1971 provincial elections, the Liberals lost control of the legislature to the Progressive Conservative Party. Conservative leader Frank D. Moores became premier in 1972, ending 23 years of Liberal Party rule under Joseph R. Smallwood. Moores and his successor, A. Brian Peckford, also a Conservative, held the premiership for most of the 1970's and 1980's. The Liberals regained power in 1989.

**Recent developments.** From the time it became a province to the mid-1970's, Newfoundland's population grew rapidly. The growing population made it difficult to provide enough jobs. As a result, many people left the province to find work. In 1979, a major oil field was found off the eastern coast. But low oil prices contributed to a delay in the development of the field, and oil production did not begin until 1997. Provincial leaders hope the field will create enough new jobs to bring people back to the province.

In the early 1990's, the federal government banned fishing for cod in waters in and around Newfoundland because of a sharp drop in their numbers. The government also placed restrictions on other species. In 1994, the Northwest Atlantic Fisheries Organization (NAFO) agreed to observe the ban and restrictions. NAFO includes Canada and a number of other nations. More than 30,000 Newfoundland and Labrador workers have lost jobs in the fishing industry.

In 2001, Canada's Parliament changed the official name of the province to Newfoundland and Labrador.
The province's government had already been referring to the province by that name for many years.

**Newfoundland dog, NOO fuhind LAND, is one of the largest and strongest breeds of dog. Male Newfoundlands weigh about 140 pounds (64 kilograms) and stand about 28 inches (71 centimeters) high at the shoulder. Females are slightly smaller. Newfoundlands have a thick coat that protects against all types of weather. The most common color is black, often with a patch of white on the chest, chin, or toes. These dogs also may be gray, brown, or white with black markings.**

No one knows exactly when the Newfoundland was developed. The breed was used for heavy work, both on land and in water. Early steamships and sailing vessels frequently included a Newfoundland as a crew member. These dogs are still known for their work in the water and their tendency to help swimmers in distress.

Newfoundlands are even-tempered, intelligent, and confident. Their patience, playfulness, and protective-ness make them excellent companions for children.

**Newgate Prison**, a London jail, was England's main criminal prison for over 700 years. It was torn down in 1902, after years of protest about its shameful condition. The prison originally was part of London's West Gate, an entranceway to the city. West Gate was rebuilt and renamed Newgate in the 1100's. Prisoners were held in a room above the entranceway. Newgate was rebuilt again about 1423. But the Great Fire of London damaged it in 1666, and its condition grew steadily worse. Many prisoners died because of overcrowded rooms, poor food, and such contagious diseases as jail fever/typhus. Women, children, and debtors lived with hardened criminals. Few reforms were adopted until the 1800's. After 1815, debtors were held elsewhere. After 1847, only people awaiting trial were kept at Newgate.

**Newman, Barnett** (1905-1970), an American painter, was a leading member of the Abstract Expressionist movement. Newman developed an extremely simple style. Most of his works consist of a large vertical stripe on a background of one intense color. Newman used exceptionally large surfaces to induce viewers to scan his paintings extensively and thereby sense their vast scale and spacious, uncluttered vision. He believed that the abstract nature of his paintings gave them philosophical and spiritual meaning.

Newman began to paint in his simplified style in 1949. His works became highly controversial and were often attacked during the 1950's. However, his style had a strong impact on many painters of the 1960's and 1970's.

Newman helped establish the principles of Minimal Art, an American style that rejected emotion and subjective matter in painting and emphasized color and form. His use of large areas of color also influenced a movement called Color-Field Painting. Newman was born in New York City.

**Newman, John Henry** (1801-1890), became a convert to the Roman Catholic Church in 1845 and was made a cardinal in 1879. Before his conversion, he had distinguished himself as a scholar and a preacher of the Church of England at Oxford University. In 1833, he joined the movement within that church to rid it of political domination and to ground it more firmly in traditional beliefs (see Oxford Movement). The movement helped strengthen the established church, but Newman shocked his fellow reformers when he joined the Roman Catholic Church. In 1846, he became a Catholic priest.
Newman was born in London. For most of his life as a Catholic, he lived in Birmingham as rector of an Oratory, a group of men devoted to prayer and studies. He was considered one of the great thinkers of the 1800's. His autobiography, the Apologia pro Vito Sua (1864), was an answer to an attack upon him by Charles Kingsley, an Anglican minister and author. Among Cardinal Newman's many lectures is The Idea of a University (1852). The Grammar of Assent (1870) was his answer to religious skepticism. Newman also wrote the words of the hymn "Lead, Kindly Light." Peter W. Williams

Newman was born in Cleveland and studied acting at Kenyon College, Yale University, and the Actors Studio. He made his Broadway debut in Picnic (1953) after appearing in several television dramas. Newman's first movie was The Silver Chalice (1953). He gained stardom in Somebody Up There Likes Me (1957).

Louis Giannetti

Newport, Rhode Island (pop. 26,475), is best known as a summer resort. The city lies on Narragansett Bay (see Rhode Island (political map)). Today, Newport is also a tourist and convention center. Its attractions include more than 300 buildings from colonial days. One of them, the Colony House, was built in 1739 and served as one of Rhode Island's capitols until 1900. Another historic landmark is the Touro Synagogue. Built in 1763, it is the oldest Jewish house of worship in the United States. The city hosts the annual Newport Music Festival. Newport was founded in 1639 by nine families from the Massachusetts Bay Colony who sought religious freedom. Before the Revolutionary War in America (1775-1783), Newport rivaled Boston and New York City as a shipping center. The city won fame in the late 1800's as the summer home of wealthy railroad and banking families. Newport is the home of the Naval War College and Salve Regina University. It has a council-manager government.

Stanford E. Dernars

See also Rhode Island (Places to visit; pictures).

Newport News (pop. 180,150) is a shipbuilding center in eastern Virginia. It lies on the north shore of the harbor called Hampton Roads. See Hampton Roads; Virginia (political map). Newport News is part of a metropolitan area that includes Norfolk and Virginia Beach. The area has a population of 1,569,541.

Newport News Shipbuilding is Virginia's largest private employer. It operates one of the largest privately owned shipyards in the world. The city of Newport News is a large coal-exporting center. Other industries include seafood processing and the manufacture of automotive parts, electronic components, escalators, laser printers, and photocopiers. Newport News is the home of The Mariners' Museum.

Newport News was named for Captain Christopher Newport, who led a group of colonists to Jamestown, Virginia, in 1607. He reportedly brought news that more colonists were on the way. Although settlement began in Newport News around 1620, the area did not develop as a city until the railroad arrived in 1881. Newport News merged with Warwick and took over Warwick County in 1958. It has a council-manager form of government.

News media. See Journalism.

News service is an organization that collects and distributes news. Many newspapers and television and radio stations rely on news services for national and international news. Few papers and stations can afford their own national and foreign correspondents. News services developed from organizations set up in Europe during the 1820's and 1830's to provide economic news to private clients. News services were once known as wire services because they sent their reports by wire to printing devices called teletypewriters. News services have reporters stationed in major cities throughout the world. These companies transmit the news gathered by their reporters and others to newspapers and other news organizations that pay for this service. The news text and photographs are sent by satellite or wire. Television and radio stations also subscribe to news services for news summaries written to be broadcast by local announcers.

In the United States, news services provide most of the foreign and national news reported by the press. All subscribers to a service receive the same national and international stories. In addition, each subscriber gets regional news, weather, and sports items. The major news services include the Associated Press (AP) and United Press International (UPI) of the United States, Reuters of the United Kingdom, ITAR of Russia (called ITAR-TASS in its bureaus outside of Russia), Agence France-Presse of France, and Xinhua of China.

Some large newspaper groups with their own staff of national and foreign correspondents operate a form of news service that is sometimes called a news syndicate. These papers sell subscribers stories that appear in the publications themselves. Other news services, called feature syndicates, provide a variety of materials, including columns of health advice, humor, and political opinion; editorial cartoons; and crossword puzzles.

Television news services furnish visual world coverage for televised news. These companies send newscasts and filmed or taped segments of news events to member television stations.

Newspaper

Newspaper is a publication devoted chiefly to presenting and commenting on the news. Newspapers provide an excellent means of keeping well informed on current events. They also play a vital role in shaping public opinion.

Newspapers have certain advantages over the other major news media—television, radio, and newsmagazines. For example, newspapers can cover more news—and in much greater detail—than can television and radio newscasts. Newsmagazines focus on chief national and international events. But newspapers report local as well as national and international news.

A large daily newspaper provides a great variety of information. News stories cover the latest developments in such fields as government, politics, sports, science, business, and the arts. Other news stories report crimes, disasters, and special events of human interest. Editorials and columns of opinion often comment on controversial issues. Informative feature articles examine a wide range of subjects, including psychology, fashion, health, and child care. Most daily papers also carry comic strips, advice columns, and other entertainment items.

Producing a daily newspaper requires great speed and efficiency. Reporters, editors, and photographers work under the constant pressure of deadlines. A large daily newspaper also employs many other workers, including advertising salespeople, artists, librarians, printing-press operators, and truckdrivers.

This article describes the kinds, organization, production, and business operations of newspapers in the United States. It then discusses newspapers in other countries and traces the history of newspapers. For information on major issues in U.S. journalism, see the article Journalism.

Kinds of newspapers

Newspapers are printed on coarse paper called newsprint. There are two major sizes of newspapers—standard and tabloid. A standard-sized newspaper in the United States has pages that measure about 13 by 21 1/2 inches (33 by 55 centimeters). The pages of a tabloid are about 9 1/4 by 14 3/4 inches (25 by 37 centimeters).

The standard and tabloid sizes are both used in publishing all printed newspapers. The three main kinds of printed papers are (1) daily newspapers, (2) weekly newspapers, and (3) special-interest newspapers. In addition, many newspaper publishers maintain online newspapers, which provide news information that computer users can access via the Internet.

Daily newspapers print world, national, state, and local news. They also carry editorials, opinion columns, feature articles, and entertainment items. Big-city dailies print many stories on social and political issues, such as the quality of schools and the efficiency of government. Many metropolitan papers include a section of suburban news several times a week. Some dailies are distributed in the evening, and others are morning papers. Some daily papers in large cities publish both a morning edition and an evening edition. Only a few large cities have more than one daily newspaper. The United States has about 1,500 daily newspapers. The total circulation of U.S. dailies is about 60 million copies. The largest dailies sell more than a million copies.

Additional features and more advertising make Sunday newspapers much larger than weekday editions. Numerous Sunday papers have special sections on such
topics as entertainment, finance, and travel. Many also include a Sunday magazine, a guide to television programs, and comics in color.

In the United States, most daily newspapers chiefly serve a particular metropolitan area or local region. Many other countries, however, have newspapers with a national circulation. In these countries, most governmental decisions are made on the national level. However, in the United States, many governmental decisions are made locally. Largely for that reason, there are few national newspapers in the United States. Instead, the country has many small newspapers that report local happenings.

**Weekly newspapers** in general, serve much smaller areas than daily papers and publish news of a more personal nature. In small communities, many people know one another and take great interest in the activities of their friends and neighbors. Weddings, births, and deaths are major news items. A fire or traffic accident gets front-page coverage in a weekly newspaper. Weeklies also report news of local business and politics. Most weekly newspapers do not carry state, national, or world news. The United States has about 7,600 weekly newspapers.

**Special-interest newspapers** print news of concern to particular groups. Many business associations and labor unions publish newspapers for their members. Newspapers printed in foreign languages serve foreign-born residents in big cities. Some newspapers specialize in news about African Americans, Asian Americans, Hispanics, and other ethnic groups. Special-interest papers may also focus on specific topics, such as sports or the arts. Many high schools and most colleges also have a newspaper of their own.

**Online newspapers** are not distributed in printed form. Instead, they are produced as collections of information found at electronic addresses called *Web sites* on the World Wide Web, a system of computer files linked together on the Internet. Many newspapers, especially dailies, produce an online version in addition to a printed version. Some online newspapers include many of the same news stories and features that appear in the printed version. Others include expanded articles, additional commentary on news stories, and features that do not appear in their printed version, primarily because of space limitations. The online versions of some major papers have certain information that is available only by subscription, for which a computer user pays a fee. The user must enter a password to gain access to the information.

**The staff of a newspaper**

The number of people needed to produce a newspaper varies widely. The smallest weekly papers have only 1 to 3 workers, who do everything from writing the news, to selling ads, to running the press. Some larger weeklies employ 10 to 30 people. The largest metropolitan dailies have 2,000 or more employees.

The staff of most dailies is headed by the publisher, who directs all the departments. The staff of such a paper is divided into three main departments: (1) editorial, (2) business, and (3) mechanical.

**The editorial department** is responsible for the news and features that the paper prints. The head of the department is called the editor in chief, executive editor, or simply editor. This individual must have a thorough knowledge of all phases of newspaper work and know how to deal well with people.

© Pam Roberts, *Ely Echo*

Staff members of a small weekly newspaper generally perform a greater variety of tasks than their counterparts at a large daily newspaper. A staff of only a few people must do all the work, from gathering and writing the news to printing the paper. These editors are checking the facts in a story.
A managing editor helps the editor in chief direct the members of the editorial staff. Under the managing editor are assistant managing editors and news editors. Other editors have charge of news in certain areas. For example, most large dailies have a city editor, a suburban editor, a national editor, a feature editor, and an international editor. Each of the various sections and departments of the paper, such as the sports, arts, and financial sections, also has its own editor. Each editor supervises a staff of reporters, writers, and other workers. Some editors, such as the sports and financial editors, may write a daily column in addition to their supervisory duties. An art director works with the editors in planning the illustrations and photographs to accompany stories. The art director oversees a staff of artists and photographers.

The editor in chief directs the news staff and editorial writers. In many cases, the publisher helps guide these writers. For that reason, a newspaper’s editorials often express the views of the publisher. Metropolitan dailies also employ special columnists to write columns of humor, advice, or general information.

Many newspapers provide special facilities to assist the editorial staff. For example, a library keeps copies of past stories and pictures plus such resources as almanacs and encyclopedias. The library also has computers for searching national and international databases. In addition, artists need special facilities to do their work. Some newspapers have a lab where photographic film can be developed quickly.

The business department tries to ensure that the paper makes a profit. A business manager heads the department with the help of an advertising manager, a circulation manager, and a promotion manager. The advertising manager directs a staff that sells advertising space to stores, manufacturers, and other businesses as well as classified ads to individuals and firms. The circulation manager supervises the distribution of the newspaper. The promotion manager develops ways of drawing attention to the paper to attract new readers and advertisers. The business department also has accountants and bookkeepers to handle the financial records.

The mechanical department prints the newspaper. A production manager directs the department’s operations. Some workers create layouts of pages, and others set the type. Still other workers produce the printing plates from which the newspaper is printed. The printing-press operators lock the plates on the presses and print the papers. Mailroom personnel assemble the papers and turn them over to the circulation department.

How newspapers are produced

Gathering information is the first step in the production of the news in a newspaper. A paper gets the news it prints from two main sources: (1) its own reporters and (2) news services.

Reporters use interviews, research, and investigative techniques to gather information for their stories. They must have well-developed news judgment to sort out important stories from those with little public interest.

A newspaper employs several kinds of reporters. Many reporters cover a specialty called a beat. Some beat reporters are assigned to particular locations, including city hall, police headquarters, and the criminal courts. Other beat reporters cover a particular subject, such as science, religion, education, or consumer affairs. Certain other reporters, called general assignment reporters, cover any story to which they are assigned or which they find on their own.

The news staff of a big-city newspaper also includes investigative reporters and stringers. Investigative reporters search out and expose political corruption or other wrongdoing. They may work weeks or months to get a story or a series of stories. Stringers do not work full time for the newspaper, but they occasionally write a story for it. Many stringers for big-city newspapers have a regular job with a suburban newspaper, a regional magazine, or a small radio station.

Many metropolitan papers have a staff of reporters in the state capital and in Washington, D.C. The largest pa-
papers also have foreign correspondents in such cities as London, Paris, Moscow, and Tokyo.

News services. Not even the largest newspapers can afford to have reporters in all the major cities of the United States and the world. As a result, newspapers depend on news services for at least part of their national and international news. The chief U.S. news services are the Associated Press (AP) and United Press International (UPI). Each of these services has reporters throughout the United States and throughout the world. Major news services in other countries include Agence France-Presse in France, Reuters in the United Kingdom, and ITAR in Russia (called ITAR-TASS in its bureaus outside Russia). News services were formerly known as wire services because they sent their stories by wire to printing devices called teletypewriters. Today, satellites are widely used to relay stories and photographs.

Many papers also get news from news syndicates. A news syndicate is owned by a newspaper or chain of newspapers with a large staff of reporters worldwide. Newspapers also receive many press releases from private companies and government departments. An organization's press release sometimes leads to major news coverage of the event it describes.

Writing and editing stories. In writing a news story, reporters begin by giving the important facts in the first paragraph, which is called the lead. They then present details in the rest of the space given to the story by the city editor or news editor. The completed story goes to a copy editor, or copyreader, who checks it for accuracy and writes a headline for it. The copy editor may change the wording to make the story more readable. The copy editor must also cut material if the story is too long. A proofreader checks the story for spelling and punctuation errors.

Most reporters and editors prepare their stories on computers that have word processing software. The computers are linked in a network so that several individuals can use their own computers to perform successive writing and editing operations on a single story.

Many stories are accompanied by photographs, charts, or illustrations. Some photos, especially those of major news events, come from news services. They may be received over telephone lines or by satellite. Most newspapers also have a staff of photographers who take pictures of local events. Graphic artists usually design charts and illustrations on computers.

Writing editorials and features. A newspaper's editorial writers hold meetings to select topics for editorials. They also decide what viewpoint to take in the editorials. Unlike a news story, an editorial expresses an opinion and tries to sway readers to that way of thinking. Feature writers prepare stories on subjects they think would interest the newspaper's readers. Common types of feature articles include interviews with famous entertainers, stories on unusual organizations, and descriptions of places to visit. Newspapers also get feature material from feature syndicates, which resemble news syndicates. Feature syndicates provide such items as political cartoons, comic strips, crossword puzzles, and columns on chess, gardening, and financial matters.

Preparing advertisements. Newspapers carry two forms of advertising—display ads and classified ads. Most display ads include illustrations and may be as large as two pages. Some metropolitan newspapers add booklets of display ads, called inserts, to the newspaper. Many newspapers have a staff of graphic artists to help prepare display ads. Classified ads, also called want ads, usually appear in a separate section of the newspaper. Most consist of a few lines of print and advertise such things as used cars or apartments for rent.

Making up the pages. Artists prepare a layout, or sketch, of each newspaper page. A layout shows where the stories, pictures, and advertisements should appear on the page. Most newspapers use computers to create layouts. Computer layouts enable artists to make precise measurements and to rearrange page contents quickly.

Many newspapers also assemble the pages by computer. Workers merge two kinds of files, following the layouts: (1) text files, and (2) graphics files. Text files consist of the words in stories, advertising copy, and other material. Graphics files are digital representations of photographs and other illustrations. Some graphics are photographed with digital cameras or are received as computer data from outside sources. Photographs shot on film and illustrations drawn on paper are converted to digital form using an electronic device called a scanner. Workers using a computer to assemble a page can see exactly where the text and the illustrations, which are represented by boxes called windows, will appear on the page.

An older method of making up pages uses images of illustrations and individual columns of type on paper. A special machine coats the back of the paper with wax, which makes the paper stick to plastic. Using the layout as a guide, workers prepare a paste-up by attaching the pieces of paper for one or two pages to a large plastic sheet.

When pages are produced and assembled on a computer, any of several methods may be used to produce printing plates. In one method, called computer-to-plate or direct-to-plate, the digital files representing the pages are transmitted electronically to an imagesetter or platesetting device, which produces the printing plates. In another method, the page is printed out on a computer printer. The text and graphics appear where the worker positioned the windows. The printed page may then be photographed to produce a negative. Or the page

Newspaper terms

Banner is the top headline on page 1.
Beat is a news field in which a reporter is regularly assigned, such as city hall or consumer affairs.
By-line is the name of the writer of a news story, feature article, or special column. In most cases, it appears just beneath the headline.
Copy means the manuscript of any news matter prepared for typesetting.
Dateline refers to the line at the beginning of a news story that tells where and, in some cases, when the story originated.
Edition means any issue of the newspaper. Large newspapers issue several editions during the day or night.
Lead is the opening paragraph of a news story. In most cases, it summarizes the important information in the story.
 Masthead includes the title of the newspaper and the names of the publisher and principal editors. In most cases, it appears on the editorial page.
Subhead is a short heading used to break up the paragraphs of a long news story.
How a newspaper is produced

The pictures on this page show some of the steps commonly used in producing newspapers and preparing them for shipment. Some publishers use different methods for laying out pages.

Writing a story. A reporter gathers information by doing research and performing interviews. The writer then uses a computer with word-processing software to prepare the story.

Assembling a page. With the aid of a computer, a worker lays out the stories and the other elements of the page. The layout can be transmitted electronically to a laser platesetter.

Mounting the printing plate. A worker wraps the printing plate around a cylinder on the printing press. The plate is made so that ink will adhere only to the image areas.

Printing a newspaper. A newspaper is printed by offset lithography. Ink transfers from the printing plates to rubber blanket cylinders and then to a long roll of paper.

Producing individual newspapers. Special equipment cuts sections from the printed roll and folds them to make individual newspapers. The papers are ready to be bundled for shipment.

Shipping the newspapers. Most of the papers are bundled and sent to a loading dock. Workers put the papers on trucks, which deliver them to newsstands and distribution centers.
image can be transferred onto light-sensitive paper or film that will then be transferred to a printing plate. For certain applications, a negative is produced with the graphics windows taking the place of the illustrations. A worker then cuts away the paper or plastic from the image areas, and inserts negatives of the graphics. When pages are assembled via the paste-up method, workers photograph the sheets to make negatives of the pages.

**Printing the newspaper.** Most newspapers use a printing method called **offset lithography.** In offset, as it is usually called, the image to be printed is on the same level of the printing plate as the areas that do not print. Offset is done on **rotary presses,** which have cylinders that hold curved printing plates. The plate does not come into contact with the paper. Instead, the printed images are transferred—that is, offset—to a rubber "blanket" cylinder that then prints them on the paper.

In one common method of producing a plate, the negative of a page is placed on a thin metal or plastic plate with a light-sensitive coating and exposed to bright light. The light passes through the transparent (image) parts of the negative and hardens the coating under these parts. The other parts of the negative block the light, and the coating under them remains soft. Workers treat the plate with a solution of developer and lacquer. The lacquer adheres only to the hardened image areas. The plate is washed, and a gum is applied to thoroughly cleanse the nonimage areas so they will repel any ink. During printing, only the lacquered areas accept ink. For more information on the production of plates, see **Photoengraving and photolithography.**

Printers mount the plates on the rotary press. After all the plates have been made and are mounted on the press, the press goes into action. In the most commonly used kind of press, a large web (roll) of paper is drawn between the blanket cylinders, receiving the print images of all the plates. The printed pages are transferred to a machine that cuts the sheets and folds them into pages. Other machines place the different sections of the paper together and stack the newspapers into piles.

Some newspapers are printed by methods other than offset. For more information on printing, see **Printing (Methods of printing).**

**Business operations**

Newspapers in the United States earn about three-fourths of their income from the sale of advertising. Most newspapers get the rest of their income from sales of the paper. The syndication of news stories or features provides additional revenue for some large papers. A newspaper's advertising department handles the sale of ads, and the circulation department manages the distribution and sales of the newspaper. Some special-interest newspapers are circulated without charge and earn all their income from advertising.

**Advertising** fills about half of the space in U.S. newspapers. Papers sell most of this space to local businesses and individuals. National firms buy the rest.

The advertising manager of a large newspaper directs division supervisors. The division supervisors have charge of various kinds of advertising, such as advertising for automobile dealers, department stores, and supermarkets. Each division supervisor has a staff of sales representatives who sell ads to businesses. Workers in

---

**A newspaper display advertisement** is inserted on a page electronically. An advertising agency prepared the ad and handled the purchase of the newspaper space for it.

---

the classified-ad department sell ads over the telephone. They also help people write their want ads. People may also purchase ads through a newspaper's Web site. In addition to the local advertising staff, many newspapers have sales representatives in other cities.

**Circulation.** Newspaper distribution is a complex operation. After the papers are printed and assembled, conveyor belts carry them to the mailroom. Most of the papers are grouped into bundles with plastic strapping. The rest are addressed for mailing. The bundles travel on chutes to a loading dock, where trucks wait to haul them to newstands and distribution centers.

National newspapers are printed simultaneously throughout the country. Communications satellites relay images of the newspaper pages to printing plants in major cities. Some large metropolitan papers have a central plant as well as plants in outlying areas that print the paper from satellite images.

The circulation manager oversees the distribution of papers and works with the promotion manager to try to increase the number of readers. Supervisors of city sales, suburban sales, and home delivery work under the circulation manager. District circulation supervisors look after sales in various areas of the city or suburbs. Independent newspaper carriers also make up an important part of the distribution system. They pick up papers at distribution centers and deliver them to homes in the city and suburbs.

**Newspapers in other countries**

Newspapers in most countries have far fewer pages than do those in the United States. Many papers in other countries have no more than 8 or 10 pages. They devote more of their stories to political and governmental affairs, and they have fewer ads and features.

Norway leads the world in newspaper readership with about 700 copies sold daily for every 1,000 people.
Other countries with exceptionally high newspaper readership include Japan, Finland, and Sweden. Circulation in the United States averages about 200 copies for every 1,000 people. In general, circulations are large in industrialized nations. Poverty and illiteracy restrict readership in developing countries. Many publishers in industrialized countries maintain online versions of their daily newspapers.

In most nations, the government controls to some extent what newspapers may publish. Governmental control of the news media is strongest in Communist nations. In these nations, the government owns and operates the media. Many countries in Africa, Asia, and Latin America severely restrict press freedom. In these countries, the government controls the press through censorship or through laws that make it dangerous to criticize the government. Only a small minority of nations allow newspapers to print any news they wish. Freedom of the press exists mainly in English-speaking nations, in most of the countries of Western Europe, and in Israel and Japan. See Freedom of the press.

In Canada, newspapers are similar to U.S. papers in size and content. Canada has about 120 daily newspapers and more than 800 weekly papers. Two newspaper chains—Southam Newspapers and Thomson Newspapers—own about half the nation's dailies and control about half the daily circulation.

The leading English-language dailies include The Gazette of Montreal and two Toronto papers—The Toronto Star and The Globe and Mail. La Journal de Montréal is Canada's largest French-language daily.

In Europe, the United Kingdom's papers most closely resemble those of the United States and Canada. All the largest British newspapers have their main offices in London and are distributed nationally. They include the country's most influential papers, The Times, The Guardian, The Independent, the Daily Telegraph, and the Financial Times. The British papers with the highest circulations include the Daily Mail, the Daily Mirror and The Sun.

Before World War II (1939-1945), most newspapers in France were associated with some political party or special-interest group. Each of these papers wrote its news from a particular political viewpoint. Today, the Communist paper L'Humañité is the only party paper with a wide circulation in France. Other French papers have political leanings, but they report news from a basically neutral point of view. Some French newspapers, such as the Paris papers Le Figaro and Le Monde, provide excellent coverage of the arts. Other French newspapers that are widely circulated include La Croix, France-Soir, and Le Parisien Libéré. All of these newspapers are published in Paris.

Newspaper circulation is generally smaller in Russia than in most European countries. Russia's leading daily newspapers are Komsomolskaya Pravda and Trud. Other large dailies include Moskovsky Komsomolets and Izvestia.

In Germany, the daily with the highest circulation is Bild Zeitung of Hamburg. It is printed in 15 of Germany's 16 states and has a circulation of about 5 million. Outstanding German newspapers include the Frankfurter Allgemeine Zeitung of Frankfurt (am Main), Süddeutsche Zeitung of Munich, Die Welt of Bonn, and Berliner Zeitung of Berlin. Italy's leading papers include La Stampa of Turin, La Repubblica of Rome, and Il Giorno and Corriere della Sera of Milan.

In Africa and the Middle East, the governments of most nations maintain tight control over what appears in the press. Israel and South Africa have a free press. But the governments of both countries exercise control over certain types of information, such as military news. Most Arab countries have laws that allow government officials to censor news before publication. In Egypt, the government owns all the newspapers, including Al Ahram of Cairo, the Arab world's most influential paper.

In Latin America, government control of the press is common. Some Latin American nations officially restrict what newspapers may print. Certain others practice indirect forms of censorship. For example, the government may own the nation's paper supplies. In that case, a newspaper that criticizes government leaders may find it difficult to buy newsprint. Major Latin American newspapers include La Prensa and La Nación of Buenos Aires, Argentina; O Estado de São Paulo of São Paulo, Brazil; and Excélsior of Mexico City, Mexico.

In Asia, Japan and China have the most highly developed press systems. Japan's leading dailies—Asahi Shimbun, Mainichi Shimbun, and Yomiuri Shimbun—circulate nationally. Each publishes a Tokyo edition and several regional editions. Yomiuri Shimbun has the largest circulation of any paper in the world—more than 14 million copies per day. One of China's largest newspapers is Renmin Ribao (People's Daily) of Beijing, the official paper of the Chinese Communist Party.

In Australia and New Zealand, newspapers resemble those of the United States and Canada. Major dailies in Australia include The Daily Telegraph-Mirror and The Sydney Morning Herald, both of Sydney, and the Herald-Sun and The Age, both of Melbourne. New Zealand's leading daily is The New Zealand Herald, published in Auckland.

History

Handwritten newsheets posted in public places probably were the first newspapers. The earliest known daily newsheet was Acta Diurna (Daily Events), which started in Rome in 59 B.C. The world's first printed newspaper was a Chinese circular called Dibao, also spelled Tripao. The Chinese began printing Dibao from carved wooden blocks around A.D. 700. The first regularly published newspaper in Europe, Avisa Relation oder Zeitung, started in Germany in 1609.

Development of U.S. newspapers. In 1690, Benjamin Harris of Boston founded Publick Occurrences Both Forreign and Domestick, the first newspaper in the American Colonies. However, the colonial government ordered it stopped after one issue. In 1704, John Campbell established The Boston News-Letter, the colonies' first regularly published newspaper. By 1765, the colonies had more than 20 newspapers.

Newspapers in the United States developed rapidly in the 1800's. By 1830, the country had about 1,000 papers. However, they were available only by subscription, and they cost about 6 cents a copy, which was more than working-class people could afford. Then in 1833, Benjamin H. Day started the New York Sun, the first of many successful penny newspapers. In the late 1800's, papers
tried to outdo one another with sensational reports of crimes, disasters, and scandals. The most sensational newspapers included two New York City dailies—William Randolph Hearst’s *Journal* and Joseph Pulitzer’s *World.* Edward Wyrill Scripps established the first newspaper chain during the late 1800’s. The number of U.S. newspapers peaked in 1909, when the country had about 2,600 dailies and about 14,000 weeklies. For more on the early history of U.S. newspapers, see *Journalism* (History).

**Recent trends.** High operating expenses, especially the rising cost of labor and newsprint, have driven many U.S. newspapers out of business. Few cities have competing dailies. In some cities with competing dailies, rival publishers print their papers on the same presses to reduce costs. Financial problems have hit hardest at major metropolitan papers, which face special distribution problems plus increasing competition from suburban papers, TV newscasts, and the Internet. Some big-city papers began publishing a second daily edition in an effort to gain wider readership.

Since the 1960’s, newspaper chains have bought up papers at an especially rapid rate. Today, the 10 largest chains account for more than half of the total daily circulation in the United States. More than 80 percent of all United States dailies belong to chains. The nation’s largest chain is Gannett Company, Inc., which owns nearly 100 papers. Other major chains include Advance Publications, Inc.; Dow Jones & Company, Inc.; Knight-Ridder Inc.; The New York Times Company; and the Tribune Company.

Most newspapers today use computerized systems for laying out and assembling pages. Reporters can write stories on portable computers and then send the stories to the office via a computer network.

In 1980, *The Columbus (Ohio) Dispatch* became the first electronic newspaper in the United States. In addition to printing a regular edition, the paper began transmitting some of its editorial content to computers in the homes, businesses, and libraries of a small number of subscribers. Today, several papers offer online newspapers. Computer users can use the Internet to access news stories, classified ads, and other features. Some newspapers also distribute their pages via fax machines.

Newspaper Guild is a labor union whose members work in the news and commercial departments of newspapers, news magazines, news services, and related enterprises. The Newspaper Guild has local organizations in more than 100 cities in the United States, Canada, and Puerto Rico.

The guild has negotiated shorter hours, higher wages, severance pay, and greater job security for its members. It has contracts with newspapers whose combined circulation totals about one-fourth of the daily newspaper circulation in the United States.

The Newspaper Guild is affiliated with the AFL-CIO and the Canadian Labour Congress. The union was founded in 1933, and it was called the American Newspaper Guild until 1971. The Newspaper Guild’s headquarters are in Silver Spring, Maryland.

Critically reviewed by the Newspaper Guild

Newsprint. See Paper (Special kinds of paper).

Newt, noot, is a small animal with a slender body, thin skin, and four weak legs. It is a type of salamander and is classified as an amphibian, along with frogs and caecilians (see Amphibian).

Newts and other salamanders are tailed amphibians. The tail of the adult newt is flatter than that of most other salamanders. Newts hatch from eggs that are laid singly in the spring on the leaves of plants underwater. The young hatch after three to five weeks. They live in the water and breathe by means of gills. In time, they develop lungs and may take to the land. People then call them efts. Efts are bright orange and are easily seen on the forest floor. They are seldom bothered by other animals because their skin is poisonous. The efts stay on land up to seven years before they return to water to breed. They often shed their skins. If an eft loses a leg, it can grow it back. The kind of newt best known in the United States is the red-spotted newt. It is about 4 inches (10 centimeters) long. Newts eat insects, worms, and mollusks.

Don C. Forester

Scientific classification. Newts are in the class Amphibia. They belong to the salamander family, Salamandridae. The red-spotted newt is Notophthalmus viridescens.

Newton, a unit in the metric system, is used to measure force. Its symbol is N. One newton is the force required to increase or decrease the velocity of a 1-kilogram object by 1 meter per second every second. The newton was named for the English scientist Sir Isaac Newton. The number of newtons needed to accelerate an object can be calculated by using the formula \( F = ma \). The mass \( m \) of the object in kilograms is multiplied by the acceleration \( a \) in meters per second squared to determine the force \( F \).

Force is measured in pounds in the inch-pound system of measurement customarily used in the United States. One newton equals about 0.225 pound of force.

Hugh D. Young

See also Pascal.

Newton, Sir Isaac (1642-1727), was an English scientist, astronomer, and mathematician who invented a new kind of mathematics, discovered the secrets of light and color, and showed how the universe is held together. Newton is sometimes described as "one of the greatest names in the history of human thought" because of his great contributions to mathematics, physics, and astronomy.

Newton discovered how the universe is held together through his theory of gravitation. He discovered the secrets of light and color. He invented a branch of mathematics, calculus, also invented independently by Gottfried Leibniz, a German mathematician (see Calculus). Newton made these three discoveries within 18 months from 1665 to 1667.

The theories of motion and gravitation. Newton said the concept of a universal force came to him while he was alone in the country. He had been forced to flee there because of the outbreak of plague in the city of Cambridge. During this time, Newton suddenly realized that one and the same force pulls an object to Earth and keeps the moon in its orbit. He found that the force of universal gravitation makes every pair of bodies in the universe attract each other. The force depends on (1) the amount of matter in the bodies being attracted and (2) the distance between the bodies. The force by which Earth attracts or pulls a large rock is greater than the pull on a small pebble because the rock contains more matter. Earth’s pull is called the weight of the body. With this theory, Newton explained why a rock weighs more than a pebble.

He also proved that many types of motion are due to one kind of force. He showed that the gravitational force of the sun keeps the planets in their orbits, just as the
The gravitational force of the earth attracts the moon. The falling of objects on earth seems different from the motion of the moon because the objects fall straight down to the earth, while the moon moves approximately in a circle around the earth. Newton showed that the moon falls just like an object on earth. If the moon did not fall constantly toward the earth, it would move in a straight line and fly off at a tangent to its orbit. Newton calculated how much the moon falls in each second and found the distance is \( \frac{1}{200} \) of the distance an object on earth falls in a second. The moon is 60 times as far from the earth's center as such an object. Consequently, the force of the earth on an object 60 times as far away as another object is \( \frac{1}{60^2} \).

The Principia. Newton concluded his first investigations on gravity and motion in 1665 and 1666. Nothing was heard of them for nearly 20 years. His original theory had been based on an inaccurate measurement of the earth's radius, and Newton realized differences between the theory and the facts. Although he later learned the true value of the earth's size, he was not led to complete his investigation or to produce a book for publication.

One day in 1684, Edmond Halley, an English astronomer, Robert Hooke, an English scientist, and Christopher Wren, the architect, were discussing what law of force produced the visible motion of the planets around the sun. They could not solve this problem. Halley went to Cambridge to ask Newton about it. He found Newton in possession of complete proof of the law of gravity. Halley persuaded Newton to publish his findings. Halley paid all the expenses, corrected the proofs, and laid aside his own work to publish Newton's discoveries. Newton's discoveries on the laws of motion and theories of gravitation were published in 1687 in *Philosophiae Naturalis Principia Mathematica* (Mathematical Principles of Natural Philosophy). This work, usually called *Principia* or *Principia Mathematica*, is considered one of the greatest single contributions in the history of science. It includes Newton's laws of motion and theory of gravitation. It was the first book to contain a unified system of scientific principles explaining what happens on earth and in the heavens.

Light and color. Newton's discoveries in optics were equally spectacular. He published the results of his experiments and studies in *Opticks* (1704).

Newton's discoveries explained why bodies appear to be colored. The discoveries also laid the foundation for the science of spectrum analysis. This science allows us to determine the chemical composition, temperature, and even the speed of such hot, glowing bodies as a distant star or an object heated in a laboratory.

Newton discovered that sunlight is a mixture of light of all colors. He passed a beam of sunlight through a glass prism and studied the colors that were produced. A green sweater illuminated by sunlight looks green because it largely reflects the green light in the sun and absorbs most of the other colors. If the green sweater were lighted by a red light or any color light not containing green, it would not appear green.

The study of light led Newton to consider constructing a new type of telescope in which a reflecting mirror was used instead of a combination of lenses. Newton's first reflecting telescope was 6 inches (15 centimeters)
long, and, through it, Newton saw the satellites of Jupiter.

Early life. Newton was born at Woolsthorpe, Lincolnshire, on Dec. 25, 1642. He attended Grantham grammar school. As a boy, he was more interested in making mechanical devices than in studying. His youthful inventions included a small windmill that could grind wheat and corn, a water clock run by the force of dropping water, and a sundial. He left school when he was 14 to help his widowed mother manage her farm. But he spent so much time reading, he was sent back to school.

He entered Trinity College, Cambridge University, in 1661. He showed no exceptional ability during his college career and graduated in 1665 without any particular distinction. He returned to Cambridge as a fellow of Trinity College in 1667.

Newton became professor of mathematics at Cambridge in 1669. He lectured once a week on arithmetic, astronomy, geometry, optics, or other mathematical subjects. He was elected to the Royal Society in 1672.

Public life. Newton became active in public life after the publication of *Principia*. He became the Cambridge University member of Parliament in 1689 and held his seat until Parliament dissolved the following year. He became warden of the mint in 1696. He was appointed master of the mint in 1699, a position he held until his death.

In 1699, he also became a member of the Royal Society council and an associate of the French Academy. He was elected to Parliament again from the university in 1701. He left Cambridge and settled permanently in London in that same year. He became president of the Royal Society in 1703 and was reelected annually until his death. Queen Anne knighted Newton in 1705. He died in 1727 and was buried in Westminster Abbey.

Personal characteristics. Newton did not enjoy the scientific arguments that arose from his discoveries. Many new scientific theories are opposed violently when they are first announced, and Newton's did not escape criticism. He was so sensitive to such criticism that his friends had to plead with him to publish his most valuable discoveries.

Newton was a bachelor who spent only part of his time studying mathematics, physics, and astronomy. He was also a student of alchemy and made many alchemical experiments. He also spent a great deal of his time on questions of theology and Biblical chronology.

As a professor, he was very absent-minded. He showed great generosity to his nephews and nieces and to publishers and scientists who helped him in his work.

He was modest in his character. He said of himself shortly before his death, "I do not know what I may appear to the world, but to myself I seem to have been only like a boy playing on the seashore, and diverting myself in now and then finding a smoother pebble or a prettier shell than ordinary, whilst the great ocean of truth lay all undiscovered before me."

Albert Einstein, the German-born American physicist, rejected Newton's explanation of universal gravitation but not the fact of its operation. He said that his own work would have been impossible without Newton's discoveries. He also said that the concepts Newton developed "are even today still guiding our thinking in physics." — Margaret C. Jacob

Newton's rings are a series of alternating bright and dark concentric circles produced by the interference of light (see **Interference**). They occur when two microscope slides are pressed tightly together at one point, or when a slightly convex piece of glass is placed on top of a flat piece of glass. Light reflected off the flat surface travels slightly farther than—and interferes with—light reflected off the curved surface. If viewed in strong white light, such as sunlight, the rings show the colors of the spectrum. If the viewing light is a single color, the rings have only that color. The rings were named for the English scientist Sir Isaac Newton, who first studied them in detail. — David M. Roessler

**Newton's rings**, shown here, were created by pressing two microscope slides tightly together at one point.

**Next of kin** is a legal phrase for the closest blood relatives of a person who has died without making a valid will. These next of kin share in the personal property of the dead person. Each state's laws determine which relatives get the personal property left by a resident of that state who did not leave a will. Usually, such laws provide for the distribution of both real and personal property to the same people, thus treating next of kin the same as heirs (see **Heir**). The relatives sharing the property are called next of kin because they are generally the closest surviving relatives of the dead person. Thus, a dead person's children are favored over cousins in the distribution of property. — William M. McGovern

**NEY, nay** Michel, mē SHEHL (1769-1815), a French general, was one of Napoleon I's great soldiers. Ney was fiercely brave, but he was not effective as an independent commander.

Ney served with great distinction in the campaign of 1792, when the French Army of the North defeated the Prussians and Austrians. He soon distinguished himself...
by his cool courage and military skill. Napoleon made him a marshal of France in 1804. Ney received the title Duke of Elchingen for defeating the Austrians at Elchingen in 1805. He fought at Jena and Eylau and commanded an army at Friedland, where the French defeated the Russians in 1807. His conduct at Friedland won him Napoleon's praise. He took charge of Napoleon's army for the march into Russia in 1812 and became Prince of Moscow. Napoleon left the army after its defeat and hastened back to France. But Ney remained with the Grand Army during the terrible retreat from Russia.

When Napoleon was forced from power in 1814, Ney abandoned him and became a supporter of King Louis XVIII, who succeeded Napoleon. But Napoleon escaped from Elba in 1815 and landed on the coast of France. Ney told King Louis that he would "bring Napoleon back in an iron cage," and started out with an army. He met Napoleon, who was marching toward Paris with a new army. But emotion swayed Ney. He embraced Napoleon, and joined him in the march on Paris. The king fled as the army approached, and Ney and Napoleon entered the capital together.

The period of Napoleon's return to power, called the Hundred Days, ended in his defeat. Ney led the last French charge at Waterloo in 1815. But he was seized, tried for treason and rebellion, and condemned to death. He was shot on Dec. 7, 1815. Ney was born in Saarouis, in the Saar Basin in what is now Germany.

Nez Perce Indians, nezh PURS, are a tribe that lives in north-central Idaho. The rich farmlands and forests in the area form the basis for the tribe's chief industries—agriculture and lumber. Many Nez Perce also make a living by fishing, by hunting, and by gathering wild plants.

The name Nez Perce means pierced nose, but few of the Indians ever pierced their noses. In 1805, a French interpreter gave the name to the tribe after seeing some members wearing shells in their noses as decorations. The Indians kept the name, but they do not use the French form of the name, Nez Percé (pronounced "NAY puh SAY").

The Nez Perce originally lived in the region where the borders of Idaho, Oregon, and Washington meet. Prospectors overran the Nez Perce reservation after discovering gold there in the 1860's.

Part of the tribe resisted the efforts of the government to move them to a smaller reservation. In 1877, fighting broke out between the Nez Perce and U.S. troops. Joseph, a Nez Perce chief, tried to lead a band of the Indians into Canada. But he surrendered near the United States-Canadian border.

Ngo Dinh Diem, uhng oh dihn zih ehm (1901-1963), was the first president of South Vietnam. He served from 1955 until a group of army officers seized control of the government and killed him in 1963.

Diem was born in central Vietnam, the son of a government official. In the late 1940's, he worked for Vietnam's independence from France and opposed Communist control of Vietnam. In 1954, Communist-led rebels defeated the French forces in Vietnam. The country was then divided into two parts, South Vietnam and North Vietnam. Bao Dai, emperor of South Vietnam, appointed Diem as his prime minister. Diem was elected president when South Vietnam became a republic in 1955.

At first, Diem restored some order to his war-torn country. But he soon began ruling like a dictator, and he became increasingly unpopular. Special police units brutally crushed his opponents. Also, Diem was unable to stop Viet Cong (Communist-led guerrilla) attacks on villages in South Vietnam. Many of his harsh actions were attributed to advice from his brother Ngo Dinh Nhu, and his sister-in-law, Madame Nhu. Nhu and Diem were killed together.

Niagara Falls is one of the most spectacular natural wonders of North America. It is on the Niagara River, about halfway between Lakes Erie and Ontario. The river forms part of the United States-Canadian border.

Niagara Falls actually consists of two waterfalls, the Horseshoe Falls and the American Falls. The Horseshoe Falls is on the Canadian side of the border in the province of Ontario. The American Falls is on the United States side in the state of New York. At night, wide beams of colored lights illuminate the falls. About 10 million people visit Niagara Falls annually.

Description. At the falls, the Niagara River plunges into a steep, canyonlike gorge. The gorge extends beyond Niagara Falls for about 7 miles (11 kilometers), to Lewiston, N.Y. The famous Whirlpool Rapids begin about 3 miles (5 kilometers) below the falls. Here, the violent current has carved a round basin out of the rocks.
About 85 per cent of the water at Niagara Falls flows over the Horseshoe Falls. The Horseshoe Falls is about 167 feet (51 meters) high and 2,600 feet (792 meters) wide at its widest point. The American Falls is about 176 feet (54 meters) high and 1,000 feet (305 meters) wide.

The gorge is about 200 feet (61 meters) deep and consists of layers of different kinds of stone. A hard rock called dolomite about 80 feet (24 meters) thick forms the top layer. It covers softer layers of dolomite, limestone, sandstone, and shale. Water erodes soft stone faster than hard stone. For this reason, the top layer extends beyond the lower layers in many places. The Cave of the Winds, behind the American Falls, has been formed under an extended shelf of harder stone.

Through the years, the gorge has become longer and longer. The pounding water erodes the soft underlying rock layers, which causes the unsupported hard rock ledge to collapse. Niagara Falls was originally at Lewiston, but it has gradually moved about 7 miles (11 kilometers) back upstream toward Lake Erie. The ledge of the Horseshoe Falls wears away at a rate varying from about 3 inches (8 centimeters) to as much as 6 feet (2 meters) per year. The ledge of the American Falls erodes more slowly because less water flows over it. Each year, about 1 inch (2.5 centimeters) wears away.

Tourism. Niagara Falls attracts visitors throughout the year. However, most visitors come during the tourist season, from April 1 to October 31. Several steamers called The Maid of the Mist take sightseers close to the churning waters at the base of the falls. Parks line both sides of the river near Niagara Falls. Excellent views of the falls may be seen from such sites as Prospect Point, Table Rock, and Terrapin Point. Four observation towers, ranging from 282 to 500 feet (86 to 150 meters) high, also provide fine views of the falls.

Water flow. United States and Canadian hydroelectric plants divert some of the water through tunnels from the Niagara River before it reaches Niagara Falls (see Niagara River [Water power]). For scenic reasons, however, the amount of water that may be diverted is regulated by a treaty between the United States and Canada. The treaty states that at least 100,000 cubic feet (2,800 cubic meters) of water a second must pass over the falls during daylight hours of the tourist season. At other times, the flow may be decreased to 50,000 cubic feet (1,400 cubic meters) a second.

History. Niagara Falls was probably formed about 12,000 years ago, after the last great ice sheet melted from the region. The melting ice caused Lake Erie to overflow. The overflow formed the Niagara River. The river ran northward over a high cliff called the Niagara Escarpment. The Niagara River cut through the escarpment and, over the centuries, formed Niagara Falls.

Indian tribes lived in the area long before the first Europeans arrived. The name Niagara comes from the Iroquois word Onguiaha, meaning the strait.

Louis Hennepin, a Roman Catholic priest who traveled with the French explorer Robert Cavelier, Sieur de La Salle, left the first written account of Niagara Falls. In a book published in 1683, Hennepin wrote: "These waters foam and boil in a fearful manner. They thunder continually."

Large numbers of tourists began visiting Niagara Falls during the 1800s. Many hotels and taverns were built on
the American and Canadian sides of the falls. In addition, numerous industries began to operate along the Niagara River.

Some people believed that the rapid development of tourism and industry ruined the scenic beauty of the area around Niagara Falls. In 1885, the government of New York took control of the land bordering the American Falls. It then established Niagara Falls Park, covering about 430 acres (174 hectares), on the land. In 1886, Canada established Queen Victoria Park on 196 acres (79 hectares) of land near the Horseshoe Falls. Since the 1880's, much more land in the Niagara Falls area has been set aside for parks, especially on the Canadian side.

Rock slides have gradually changed the appearance of Niagara Falls through the years. In 1931, about 80,000 tons (73,000 metric tons) of rock fell from the American Falls. Several years later, approximately 30,000 tons (27,000 metric tons) of rock broke off the upper edge of the Horseshoe Falls. In 1954, about 185,000 tons (167,800 metric tons) of rock tumbled from the American Falls and nearby Prospect Point.

In 1969, U.S. Army engineers built a dam to stop the flow of water temporarily over the American Falls. A board of experts from the United States and Canada then studied the rock ledge to determine how to prevent further erosion. However, the board decided that the cost of halting erosion would be too high. It recommended that nothing be done except small measures to improve public safety.

Additional resources

Power Authority, State of New York

Power plants harness the water power of the Niagara River to generate electricity for a wide area. The Robert Moses plant and reservoir, shown here, lie on the American side of the river below Niagara Falls. Two Canadian power plants are just across the river. Both hydroelectric projects remove water from the river by tunnel before it reaches the falls.
**The falls change constantly** through erosion. The swirling currents of the Niagara River slowly wear away the walls of the gorge and sometimes cause major rock slides. In this map, the dotted lines indicate earlier positions of the falls, which are gradually moving upstream.

**The churning water** at the base of the falls eats away the soft underlying rock layers of the gorge, as shown in this diagram. The unsupported hard top rock then breaks off.

**Niagara Movement** was an organization founded by African Americans to fight racial discrimination in the United States. It existed from 1905 to 1910. At its height, the Niagara Movement had 30 branches in various American cities. It failed to win the support of most blacks, but many of the movement's ideas were adopted in 1909 by a new interracial organization—the National Association for the Advancement of Colored People (NAACP).

The Niagara Movement was founded in Niagara Falls, Canada. W. E. B. Du Bois, an African American professor at Atlanta University, led the organization (see Du Bois, W. E. B.). The movement placed the responsibility for racial problems in the United States on whites. The Niagara Movement thus opposed the view of the famous African American educator Booker T. Washington, who urged blacks to stop demanding equal rights (see Washington, Booker T.). Various branches of the movement demanded voting rights for African Americans, opposed school segregation, and worked to elect candidates who promised to fight race prejudice.

Otey M. Scruggs

**Niagara River** is a short river that connects Lake Erie and Lake Ontario. The river forms part of the border between the state of New York and the Canadian province of Ontario. Water from all the Great Lakes except Lake Ontario drains into the Niagara River. Most of this water drops over Niagara Falls, which is about halfway along the Niagara River’s course.

The Niagara River is 34 miles (55 kilometers) long. It drops 326 feet (99 meters) during its course, an unusually sharp descent for so short a river. The dramatic drop in elevation creates a swift current and some of the roughest rapids in the world. Hydroelectric power plants along the river produce much electricity.

**Description.** The Niagara River starts at Lake Erie as a quiet stream about 600 yards (550 meters) wide. The river flows north, broadens, and then divides as it passes both sides of Grand Island. Beyond the island, the river becomes about 2 miles (3 kilometers) wide. It then turns sharply west and narrows before plunging over Niagara Falls.

Beyond the falls, the Niagara River turns north again and flows swiftly through a narrow gorge about 7 miles (11 kilometers) long. The Whirlpool Rapids begin in the gorge about 3 miles (5 kilometers) below the falls. The water in the rapids twists violently and circles at a speed of about 27 miles (43 kilometers) per hour. The river forms another series of rapids below the Whirlpool Rapids and then flows quietly on before emptying into Lake Ontario.

**Water power.** Several hydroelectric power plants stand on both sides of the Niagara River below Niagara
Falls. The major power plants are the Robert Moses power plant on the American side of the river and the two Sir Adam Beck power plants on the Canadian side. The Robert Moses power plant and a nearby pumping-generating station together have a capacity of about 2,400,000 kilowatts. The Robert Moses plant is the largest hydroelectric plant in the Eastern United States and one of the largest hydroelectric plants in the world. The two Sir Adam Beck plants and a small pumping-generating station have a combined capacity of more than 1,800,000 kilowatts.

Water for the Robert Moses and Sir Adam Beck power plants is taken from the Niagara River before the river reaches Niagara Falls. The water plunges down tunnels dug along the American and Canadian sides of the river. The tunnels carry the water into canals. The water then flows into the power plants. Each of the power projects has a large reservoir. When the demand for electricity is low, water from the tunnels is pumped into the reservoirs. When the demand increases, the reservoir water is used by the pumping-generating stations to produce additional electricity.

**Commerce and Industry.** Ships cannot sail the full length of the Niagara River because of the falls and rapids. However, the nearby Welland Ship Canal, built by the Canadian government, provides a route for ships traveling between lakes Erie and Ontario (see Welland Ship Canal).

The hydroelectric power plants along the Niagara River have attracted to the region many industries that use large amounts of electricity. Most of the industries are centered in Niagara Falls, Ont, and in the area between Niagara Falls, N.Y., and Buffalo, N.Y. During the 1970s, many people in the area became concerned about water pollution caused by some of the industries.

**Niaméy, nyah MAY** (pop. 360,000), is the capital and largest city of Niger. The city lies on the Niger River in the southwestern part of the country. For location, see Niger (map).

Niaméy is the chief trade and exporting center for farm products raised in Niger. It has two market places, where people buy and sell farm products. Niaméy has some small food-processing plants, but few other industries. The city’s main buildings include government office buildings and a mosque (Muslim house of worship). Most of the people live in crowded areas along the Niger River. Niaméy has a small international airport.

In the early 1950s, France took control of Niger from black Africans who had long lived there. In 1926, the French founded Niaméy as the capital of their colony of Niger. Niger gained independence from France in 1960. Since then, Niaméy’s population has grown from about 30,000 to 360,000.

Robert L. Rolberg

**Nibelungenlied, NEE buh luhng uhn leet,** is a German epic poem written about A.D. 1200. The title means *Song of the Nibelungs.* The author is unknown, but undoubtedly came from the Danube area of southeastern Germany or Austria. Several versions of the author’s story exist today.

The poem tells of Siegfried, who owns the fabulous Nibelung treasure and a cloak of invisibility. He has also killed a dragon and bathed in its blood. The blood hard-ened Siegfried's flesh, protecting it from wounds. But a linden leaf had fallen between his shoulders while he bathed, leaving an unprotected spot on his back.

Siegfried wants to marry Kriemhild, the sister of King Gunther of Burgundy. To gain Kriemhild, Siegfried helps Gunther win the maiden Brunhild, Queen of Iceland. Brunhild will marry only the man who can overcome her in combat. So Siegfried disguises himself as Gunther, and beats Brunhild, winning her for Gunther. Years later, Kriemhild tells Brunhild that Siegfried, not Gunther, had beaten her, adding some insulting lies to the revelation. In revenge, Brunhild orders Hagen, one of Gunther's servants, to murder Siegfried. Hagen kills Siegfried by thrusting a spear into the unprotected spot on his back.

Several years later, Kriemhild marries Etzel, mighty king of the Huns. But she never forgets Siegfried. Kriemhild invites the Burgundians to visit her and has them slaughtered. Only Hagen survives. Kriemhild asks him to reveal where he has hidden the Nibelung treasure. When he refuses, she kills him. Hildebrand, a warrior at the court of Etzel, horrified by Kriemhild's treachery, kills her.

**The background.** Two actual events form the basis for parts of the *Nibelungenlied.* In A.D. 437, the Huns destroyed the Burgundians, an east Germanic tribe. The Burgundian king and members of his royal household died in the battle. The king of the Huns, Attila (called Etzel in the poem), was not connected with this event. Attila died on his wedding night in 453. Some historians said that he was murdered by his Germanic bride.

The Nibelungen-poet clearly was not the first to deal with this story material. The Icelandic *Edda,* composed before the *Nibelungenlied,* contains *lays* (short poems) on the same themes. The early Germanic peoples composed lays to celebrate the great heroes and events of their past. The lays were revised, and in the course of centuries the original historical events were greatly altered. Unknown poets combined the events of 437 and 453 into a single historic lay. In this lay, a Burgundian bride kills Attila to gain revenge for the death of her relatives, who had been killed by Attila’s Huns.

Many of the themes and much of the plot of the older Germanic lays can still be found in the *Nibelungenlied,* but the poet changed the material. Scholars have not been able to trace the *Nibelungenlied* story of Siegfried’s death to particular historical personalities and events. In fact, Siegfried’s supernatural powers give his story the quality of a fairy tale.

**The style.** The *Nibelungenlied* is written in stanzas. Each stanza consists of four long lines of two pairs of rhymed couplets. The author shows a keen understanding of human psychology in developing the motives that cause the proud figures in the poem to act as they do. The great climaxes lie in the tense dialogues in which the rivals confront each other.

Scholars cannot say precisely what the Nibelungen-poet retained and what he inserted. The courtly aspects were probably added around 1200, when courtly culture flourished in Germany. The love between Siegfried and Kriemhild, the festivals of knights and ladies, and the many heroes reflect courtly virtues. These aspects provide the softer accents that contrast with and heighten the effect of the tragic ending.

James F. Poag

**Nicaea, Councils of.** See Nicene councils.
The Nicaraguan countryside includes sharply rising mountains and grazing land for cattle and other livestock. This scene is in western Nicaragua, near the city of León.

Nicaragua

Nicaragua, nihk uh RAH gwuh, is the largest country of Central America in area. It extends from the Pacific Ocean to the Caribbean Sea. About three-fifths of the country's people live in a fertile region on the Pacific side. In this region is Managua, the capital and largest city of Nicaragua.

Most Nicaraguans have both Indian and Spanish ancestors. In the early 1500's, the Spaniards began arriving in what is now Nicaragua. They named the land for an Indian chief and his tribe—both called Nicaraq—who lived there. The Nicarao way of life, like that of most of the other Indians of Nicaragua, has blended with Spanish customs and traditions. Today, Nicaragua has only a few Indian groups that follow traditional ways of life.

Coffee and cotton are Nicaragua's leading sources of income. They are grown in the Pacific Region of western Nicaragua and in the Central Highlands. Few people live in the thickly forested Caribbean Region in the eastern part of the country.

Government

The national government of Nicaragua is headed by a president. The people elect the president—and a vice president—to five-year terms. The president appoints a cabinet to help carry out the day-to-day operations of the government. The National Assembly makes the country's laws. The people elect the 90 members of the Assembly to five-year terms. All Nicaraguans 16 years of age and older may vote in elections.

Nicaragua is divided into 15 departments and 2 autonomous (self-governing) regions on the Caribbean coast. The country is further divided into municipalities for purposes of local government. The people elect a mayor and a council to administer each municipality.

Nicaragua has a number of political parties, which often form alliances. Two major parties are the Sandinista National Liberation Front (FSLN), commonly called the Sandinistas, and the Liberal Constitutionalist Party (PLC).

The Supreme Court of Justice is Nicaragua's highest court. It hears appeals from lower courts. It has 16 judges, who are elected by the National Assembly to five-year terms.

About 12,000 people serve in the armed forces of Nicaragua, which consist of an air force, army, and navy. Service is voluntary.

People

The majority of Nicaraguans are mestizos (people with white and Indian ancestors). The way of life of the mestizos is similar to that of Spanish Americans in other Central American countries. Most Nicaraguan people belong to the Roman Catholic Church and speak Spanish. The only Indian groups in Nicaragua that still generally speak their own languages and follow their traditional ways of life live in the thinly populated Caribbean Re-

Facts in brief

| Capital: | Managua. |
| Official language: | Spanish. |
| Area: | 50,193 sq mi (130,000 km²). Greatest distances—north-south, 293 mi (472 km); east-west, 297 mi (478 km). Coaslines—Pacific, 215 mi (346 km); Caribbean, 297 mi (478 km). |
| Elevation: | Highest—Pico Mogotón, 6,913 ft (2,107 m) above sea level. Lowest—sea level along the coasts. |
| Population: | Estimated 2002 population—4,350,000; density, 107 per sq mi (41 per km²); distribution, 63 percent urban, 37 percent rural. 1995 census—4,357,009. |
| Chief products: | Agriculture—coffee, cotton, corn, sugar cane, bananas, rice, beans. Manufacturing—food and beverage products, clothing and textiles. |
| Money: | Basic unit—gold córdoba. One hundred centavos equal one gold córdoba. |
region. The Caribbean Region also has several black and mixed Indian-black communities that largely follow Indian customs and traditions.

About a third of Nicaragua's people are poor farmers. Many of those in the Pacific Region are peasants who work on their own farms, on cooperatives or state farms, or on large private farms. In warmer areas, agricultural workers live in palm- or metal-roofed houses. In the colder areas of the Central Highlands, farmers live in adobe houses with tile roofs. The Indians and blacks of the Caribbean Region live chiefly by farming small plots or by fishing, lumbering, or mining.

Nicaraguan law requires children to go to school from the age of 6 through 12. Before 1980, only about half the country's children did so, and most of these children lived in cities or towns. Nicaragua did not have enough schools, and many rural areas had no schools at all. But since then, the government has built hundreds of rural schools. The government also conducted a successful literacy campaign headed mainly by young volunteer teachers.

Nicaragua has three universities. The National University of Nicaragua, in León and Managua, is the oldest and largest university. It was founded in 1812 and has more than 22,000 students.

The land and climate

Nicaragua has three main land regions: (1) the Pacific Region, (2) the Central Highlands, and (3) the Caribbean Region. The climate is chiefly tropical, with some differences among these regions.

The Pacific Region is largely a low area extending from Honduras to Costa Rica. Several volcanoes, some of them active, are in this low area. Lake Managua and Lake Nicaragua lie in the central and southern sections. Mountains up to 3,000 feet (910 meters) high rise along the Pacific coast. Nicaragua's largest cities and many large farms are in the Pacific Region.

The region receives about 60 inches (150 centimeters) of rain a year. The rainy season lasts from May to November. Temperatures average about 80 °F (27 °C) throughout the year.

The Central Highlands make up Nicaragua's highest and coolest region. They include the country's highest point, Pico Mogotón, a peak on the border with Honduras, north of Ocotal, that rises 6,913 ft (2,107 m) above sea level. Forests cover most of the region's slopes. Deep valleys lie between the mountains.

Some areas receive over 100 inches (250 centimeters) of rain a year. Most people live on farms in drier areas. Like the Pacific Region, the Central Highlands have a rainy season from May to November. Temperatures average 60 to 70 °F (16 to 21 °C).

The Caribbean Region is mostly a flat plain, with some highlands sloping upward toward the west. Many rivers that rise in the Central Highlands flow through the plain. The region's only good farmland lies along the riverbanks. Rain forests cover most of the region. There are grasslands with palm and pine forests in the north. A number of small islands lie off the coast.

Nicaragua's flag was adopted in 1908 from that of the United Provinces of Central America. This union of the early 1800's consisted of Nicaragua and four other nations.

The coat of arms appears on the flag. The volcanoes stand for the Central American union, the triangle for equality, the rainbow for peace, and the cap for liberty.

Nicaragua is bordered by Honduras, the Caribbean Sea, Costa Rica, and the Pacific Ocean.
Easterly trade winds drench the Caribbean Region with an annual average of 165 inches (419 centimeters) of rain, which falls throughout most of the year. Temperatures in the region average 80 °F (27 °C).

Economy

Nicaragua's major natural resource is the rich soil of the Pacific Region. Ash from volcanoes makes this soil fertile. Farming is the leading economic activity, though farmland makes up only about 10 percent of the land area. Nicaragua has some deposits of copper, gold, and silver, but mining provides only a small part of the nation's income. Thick forests cover about half the land. Before 1979, foreign firms owned most of the mines and forests. Since then, the government has taken control of them. Many streams in the Central Highlands could furnish cheap hydroelectric power, but few have been used. The country is developing these power sources.

Agriculture. Exported farm products provide most of Nicaragua's income. Cotton and coffee are the most valuable crops. Cotton is grown in the low Pacific areas. Coffee is grown in the Central Highlands and the Pacific Region. Sugar cane is also grown there. Other farm exports include bananas, beef cattle, and rice. Rice is the main food crop raised for use in Nicaragua. Corn and beans are grown in all regions, but chiefly in the Central Highlands. Since 1984, the government has promoted raising corn and beans on large, modern, privately owned farms in the Pacific Region.

Manufacturing. Nicaragua's industrial center is Managua, where most of the nation's electric power is generated. As in most Central American countries, the major products are processed foods and beverages, clothing, and textiles. Other products include cement, cigarettes, and goods made of leather, petroleum, and wood. The government owns a third of Nicaragua's manufacturing companies. The rest are privately owned—about a fourth of them by foreign firms. Manufacturing activity has declined since the late 1970's.

Service industries. Wholesale and retail trade form the leading service industry in Nicaragua. The marketing of farm products is the most important type of trade in the country. Government activities rank second in importance. Other service industries include finance, insurance, and real estate, and transportation, communication, and utilities.

Foreign trade. Nicaragua's chief trading partners include the United States, Mexico, and several Western European countries. Nicaragua belongs to the Central American Common Market, an economic union of five nations.

Transportation. Nicaragua has some good roads, especially in the Pacific Region. The Pan American Highway is the major highway (see Pan American Highway). Many populated areas cannot be reached by automobile, and the people use mules or oxcarts. Nicaragua has an average of only about 1 automobile for every 100 people. There are some railways, all in the Pacific Region. Managua has an international airport.

Communication. Nicaragua has few newspapers. The largest are La Prensa and El Nuevo Diario de Managua and Barricada, the paper of the Sandinista National Liberation Front. Government-operated postal, telegraph, and telephone systems serve only cities and towns. Many of the country's radio stations and all of its television channels are publicly operated. There are several privately owned radio stations.

History

The Indian period. Little is known of what is now Nicaragua before the Spaniards arrived in the early 1500's. A series of Indian states occupied the Pacific Region and the Central Highlands. They built fortified towns, and had highly developed markets and a system of social classes that included slaves. Less developed Indian societies lived in the Caribbean Region.

The colonial period. In 1502, Christopher Columbus arrived at what is now Nicaragua, and claimed the land for Spain. A Spanish expedition from Panama explored the Pacific Region in 1522. Many of the Nicarao Indians who lived in the region were baptized into the Roman Catholic Church.

Another expedition from Panama arrived in 1524. The leader, Francisco Fernández de Córdoba, founded Granada and León near the main sources of Indian labor. The Indians worked on the Spaniards' farms and in their mines. In 1570, Nicaragua came under the control of the Audiencia of Guatemala, a high court of Spanish judges and administrators that ruled most of Central America. Nicaragua was part of the colony of New Spain, but the court had great power because it was so far from Mexico City, the colonial capital.

The Spaniards explored the Caribbean coast of Nicaragua, but did not settle there. During the 1600's and 1700's, other Europeans—chiefly the English—occupied that region from time to time. English, Dutch, and French pirates had hideouts there, and attacked Spanish shipping in the Caribbean Sea. The pirates also raided Spanish towns to the west. During the 1700's, the English gained control over the Miskito, or Mosquito, Indians of the Caribbean coast. The United Kingdom gave up its hold on the region to Nicaragua in the mid-1800's.

Independence. On Sept. 15, 1821, Nicaragua and other Central American states also declared their independence. These states later became part of the Mexican empire, but broke away in 1823 and established the
Workers load bananas at a Nicaraguan port, above. Most of Nicaragua's income comes from exported farm products, including bananas, coffee, cotton, sugar cane, and rice.

United Provinces of Central America. In general, this union followed liberal economic and political policies. For example, the member states established various civil rights. In addition they also ended the special rights of powerful nobles and the Roman Catholic Church.

The union began to collapse under various pressures, including efforts by the conservative landowners and the clergy to regain their old privileges. In 1838, Nicaragua left the union. By then, a dispute had developed between Leon, the liberal center, and Granada, the conservative center. These two cities struggled for control of Nicaragua, and fighting often broke out.

The liberals of Leon asked William Walker, an American military adventurer, to help them. In 1855, Walker arrived with a band of followers and captured Granada in a surprise attack. But instead of helping the liberals, he seized control of the government in 1856. The next year, the liberals and conservatives joined forces and drove Walker from the country.

The United States and Nicaragua. For many years, the United States had wanted to build a canal across Nicaragua to link the Atlantic and Pacific oceans. In 1901, President Jose Santos Zelaya of Nicaragua set certain limits on U.S. rights in the proposed Nicaragua Canal zone. The United States did not accept these limits, and shifted its attention to Panama as the site of the canal. Zelaya then threatened to sell rights to the canal to some rival country of the United States. He also canceled contracts with a number of U.S. firms.

In 1909, a revolt broke out against Zelaya, a harsh ruler. He was driven off office by the United States and sided with the rebels. In 1911, U.S. banks began to lend money to Nicaragua under agreements that gave them control over its finances until the debts were paid in 1925. At the request of the banks and President Adolfo Diaz, U.S. marines landed in Nicaragua in 1912 to put down forces that opposed American control. The marines remained in Nicaragua almost continuously until 1933 to protect United States interests and supervise elections.

Rebels led by General Augusto Cesar Sandino tried to make the U.S. forces leave Nicaragua. From 1927 to 1933 the rebels raided the U.S. marines from hideouts in the mountains. The United States trained a new Nicaraguan army, called the National Guard, to help the marines. Anastasio Somoza Garcia became head of the National Guard. In 1934, after the marines had left, Somoza had members of the National Guard murder Sandino.

The Somoza period. In 1936, Somoza forced President Juan Sacasa to resign. Somoza, who was Sacasa's nephew, became president the next year after an election in which he was the only candidate. He ruled as a dictator and established great political and economic power for himself and his family.

From 1937 until 1979, a Somoza ruled Nicaragua either as president or as the real power behind the government. Anastasio Somoza was assassinated in 1956, and his older son, Luis, replaced him as president. Luis held the presidency until 1963. His brother, Anastasio Somoza Debayle, became president in 1967. In general, the Somozas were eager to cooperate with the United States and had support from the U.S. government.

Political stability under the Somoza family rule attracted U.S. investments, and Nicaragua's economy expanded. The 160-mile (257-kilometer) Rama Road was built between 1968 and 1980 with U.S. aid. It helped connect the Pacific and Caribbean coasts of Nicaragua.

In 1972, an earthquake in Nicaragua killed about 5,000 people. It destroyed much of Managua. The city was rebuilt near the site of the earthquake. Also in 1972, President Anastasio Somoza Debayle turned over formal power to a civilian junta. However, he continued to rule from behind the scenes as head of the National Guard. In 1974, Somoza was elected president for six years.

Rebel victory. Widespread protests against Somoza's rule began in the mid-1970s. Protesters demanded Somoza's removal from office. Many of the opponents belonged to the Sandinista National Liberation Front, a guerrilla group. The group was named after Augusto Cesar Sandino. Many other political and economic groups joined the Sandinistas' protests.

By 1978, the conflict between the rebels and the government had become a civil war. The rebels won the war in July 1979. They forced President Somoza to resign and leave the country. They then set up a new government. In 1980, Somoza was assassinated in Paraguay.

Recent developments. The new government, headed by the Sandinistas, took over key parts of the economy, including agricultural exports, banking, insurance, and mining. But the economic system is a mixture of public and private ownership. The government adopted many policies designed to help the poor and improve the economy, which had been badly damaged in the civil war. But economic recovery from the war has been slow, and hardships remain for many people.

In the early 1980s, internal opposition to the Sandinistas developed concerning economic policy and the type of government to be established. In 1981, the United States, charging that Nicaragua was providing weapons to rebels in other Central American countries, cut off aid to the country. In that year, former members of Somoza's National Guard and others stepped up attacks from bases over the border in Honduras. In response, the Nicaraguan government declared a state of emergency and launched a campaign to build up its military
forces. In 1983, several thousand anti-Sandinista invaders invaded northeastern Nicaragua. Until 1990, fighting between the invaders—called contras—and government forces took place in Nicaragua, resulting in many deaths. The United States gave financial aid to the contras. The government was aided by the Soviet Union, Cuba, Western European nations, and other countries.

Daniel Ortega became head of the Sandinista government. In 1984, he was elected president of Nicaragua. United States President Ronald Reagan charged that the Sandinistas had set up a Communist dictatorship and were providing aid to rebels in other Central American countries. In late 1983 and early 1984, the United States aided the contras in placing mines in Nicaraguan harbors. In 1985, Reagan ordered an embargo on U.S. trade with Nicaragua. Before the embargo, the United States had been Nicaragua’s chief trading partner.

Some people in the United States opposed U.S. financial aid to the contras. In the 1980’s, the U.S. Congress voted sometimes for and sometimes against further aid to the rebels. In 1986, the International Court of Justice—after reviewing complaints from Nicaragua—concluded that the United States acted illegally in helping mine the Nicaraguan harbors and providing aid to the contras. United States officials rejected the conclusion.

In March 1988, the Sandinistas and the contras negotiated a cease-fire. They held talks to try to resolve their differences. Although no peace agreement was reached, the level of fighting declined following the talks. But fighting resumed after the government refused to extend the cease-fire past Oct. 31, 1989.

In elections held in February 1990, Violeta Barrios de Chamorro of the National Opposition Union (UNO), a group of 14 anti-Sandinista parties, was elected president. The government and the contras signed a cease-fire agreement in April 1990. By June 1990, the contra troops had been disbanded.

After the election of Chamorro, the United States ended its trade embargo with Nicaragua. During the 1990’s, the government began to privatize some areas of the economy, such as banking and mining, that had been nationalized by the Sandinistas. But Nicaragua still faced severe economic problems, including high inflation and poor industrial performance.

In a presidential election held in 1996, José Arnoldo Remén Lacayo of the rightist Liberal Alliance defeated Daniel Ortega of the Sandinistas and several other candidates. The main party in the Liberal Alliance was the Liberal Constitutionalist Party (PLC). In a 2001 presidential election, Enrique Bolaños Geyer of the PLC defeated Ortega, who again ran as the Sandinista candidate.

In 1998, Hurricane Mitch struck Nicaragua, producing floods and landslides. The storm killed about 3,000 people and caused more than $1 billion in damage.

Nice, nees (pop. 345,892; met. area pop. 888,784), is a resort city on the French Riviera and a Mediterranean port. It lies at the foot of the Alps near Italy (see France [political map]). The city has wide avenues, luxurious hotels, and villas surrounded by gardens. The Paillon River divides it into the Old Town to the east and the modern, western part. The Alps protect Nice from cold northern winds and give it a mild winter climate.

Most of the people depend for their living on the tourist trade. Most tourists come during the winter vacation season between January and April, or else from July to September. The Mardi Gras, the height of the Riviera Carnival, is one of Nice’s many winter festivals (see Mardi Gras). The industries of Nice produce olive oil, perfumes, processed fruit, soap, cement, and other products. Railroad lines to Marseille and to the Italian cities of Genoa and Turin pass through Nice. Greek settlers founded Nice about 400 B.C.
Nicene Councils, ny SEEN, were two councils of the Christian church held in Nicaea (Nicea), in what is now northwest Turkey.

The first council was called in 325 by Emperor Constantine to settle the dispute caused by the Arian views of the Trinity. Arius was a priest of Alexandria who believed that Christ is not of the same essence as God. The council adopted the so-called Nicene Creed. This declared that God and Christ as God are of the same essence. The first council also fixed the time for observing Easter. In some regions, the Christian Easter had been observed on the same day as the Jewish Passover. In others, Easter had been observed on the following Sunday.

The Nicene Creed summarized the chief articles of the Christian faith of that time. It is next oldest to the Apostles' Creed. It was adopted originally in the following form, but has been amplified since:

We believe in one God, the Father Almighty, maker of all things, both visible and invisible; and in one Lord, Jesus Christ, the Son of God, Only begotten of the Father, that is to say, of the substance of the Father. God of God and Light of Light, very God of very God, begotten, not made, being of one substance with the Father, by whom all things were made, both things in heaven and things on earth; who, for us men and for our salvation, came down and was made flesh, was made man, suffered, and rose again on the third day, went up into the heavens, and is to come again to judge both the quick and the dead; and in the Holy Ghost.

The second council was called in 787 by the Empress Irene and her son Constantine. The Emperor Leo, Irene's deceased husband, had forbidden the use of images for any purpose. The council was called because of opposition to the decree. The empress revoked the decree after the council had laid down principles governing the veneration of images. Eugene TeSelle

Nicholas I (1796-1855) was czar of Russia from 1825 to 1855. He was a hard-working leader whose conservatism kept him from moving Russia into the modern world.

Nicholas succeeded his brother Alexander I after Alexander's death in December 1825. At that time, a group of liberal army officers, who later became known as Decembrists, tried to take power. Nicholas, shocked by the rebellion, had five of the leaders executed and the others exiled to Siberia. He was determined to fight liberalism in Russia and revolution in Europe. In 1830-1831, he suppressed a Polish uprising that was aimed at freeing Poland from the Russian empire. In 1849, he sent Russian armies into Hungary to crush a revolt for Hungarian independence from Austria.

Within the Russian empire, Nicholas demanded loyalty to himself and to the Russian Orthodox Church. Censorship was severe during his reign. However, Russian literature, art, and music continued to thrive. Some reforms did occur under Nicholas. With his approval, Russia's first modern law code was issued in the 1830's. Nicholas also authorized improvements in the living conditions of certain peasants.

In 1828-1829, Nicholas won territory for Russia and helped win independence for Greece in a war with the Muslim Ottoman Empire. The Ottoman Empire was centered in what is now Turkey. In 1853, Nicholas again went to war with the Ottomans. Fearful of Russian expansion, Britain and France helped the Ottomans in what became the Crimean War. Nicholas died during the war, which Russia later lost.

Joseph T. Fuhrmann

See also Alexander II; Crimean War; Russia (History).

Nicholas II (1810-1861) was crowned pope in 1059. His reign is best known for the Lateran synod of 1059, which reformed the procedures for electing a pope. The synod issued a major decree that said the cardinal bishops would, in effect, propose a candidate for pope. Then all the cardinals would "elect," which really meant accept, the proposed candidate. The newly elected pope would be presented to the people of Rome for approval. A notice would then be sent to the Holy Roman emperor for his approval. The decree's purpose was to deny the Roman nobility the right to interfere with the choice of pope. Later, it was also applied to imperial influence on papal elections.

The synod also issued legislation to enforce celibacy of the clergy and to prohibit simony, the selling of church offices, and lay investiture, by which secular (nonreligious) rulers presented clerics to the symbols of their offices. This authority enabled rulers to control who received those offices. To secure his electoral decree, Nicholas allied the papacy with the Normans in southern Italy. At times this alliance worked effectively to protect the popes from turbulent Roman politics and from German intervention. But sometimes the Normans themselves interfered in Rome.

Nicholas was born in Burgundy, or possibly Lorraine, France. His given name was Gerhard. Thomas F. X. Noble

See also Pope (The early Middle Ages).

Nicholas II (1868-1918), the last czar of Russia, ruled from 1894 to 1917. He succeeded his father, Alexander III. Nicholas believed a czar must have absolute power and opposed parliamentary government. He possessed great personal charm but lacked the vision of a strong leader.

Nicholas was born in St. Petersburg. During his reign industry developed rapidly in Russia. Literature, science and other branches of learning also made impressive gains. But the middle class increasingly felt the monarchy was out of touch with the needs of the new industrial society. Workers in the cities became dissatisfied with living and working conditions.

Meanwhile, Nicholas attempted to expand Russian territory in Asia. This effort led to the Russo-Japanese War (1904-1905), which Russia lost. The war sharpened dissatisfaction with the government, and the people revolted in 1905. Workers joined with peasants and intellectuals to force Nicholas to grant reforms. He agreed to establish an elected legislature and granted the people civil liberties.

Beginning in 1906, Nicholas' government expanded public education, gave workers some insurance against illness and injury, and allowed peasant families to assume ownership of the village land they were farming. But these reforms were interrupted by the outbreak of World War I in 1914. Nicholas' approval of a buildup of Russian troops along the country's borders with Germany and Austria-Hungary helped trigger the war.

Russia suffered severe losses in World War I. In 1915 Nicholas assumed direct command of the army. As a result, the people blamed him for Russia's military failure. Many Russians also unjustly accused Alexander, his
Nicholas II, the last czar of Russia, and his family posed for his photograph shortly before the Russian Revolution of 1917. His czar's family included, clockwise from lower left, his son, Grand Duke Alexis; his wife, Empress Alexandra; and his daughters, the Grand Duchesses Maria, Tatiana, Olga, and Anastasia.

German-born wife, of treason. These problems and hostages of food and fuel led the people to revolt in March 1917. Nicholas lost all political support, and he gave up his throne on March 15.

In November 1917, revolutionaries called Bolsheviks later known as Communists seized power. They imprisoned Nicholas and his wife and children in Yekaterinburg in the Ural Mountains and killed them there on July 7, 1918.

Nicholas V (1397-1455) was elected pope in 1447. Nicholas was the first true Renaissance pope. He drew inspiration from intellectual developments in Florence, the leading humanist center in Italy (see Renaissance Humanism). Nicholas spent vast sums on an important collection of ancient Greek, Roman, and early church manuscripts. These writings became the core of the Vatican library. Nicholas sponsored many humanists in Rome as artisans of Greek works into Latin, seeing the papacy not only as head of the church but also as head of Western civilization.

Nicholas aimed to once again make Rome the capital of the Christian world. He proclaimed 1450 a jubilee year, which attracted many pilgrims to Rome. He also rebuilt many structures in the city and made ambitious plans to rebuild the Vatican. Nicholas was born in Sarzana, Italy, near La Spezia. His given and family name was Tommaso Parentucelli.

Nicholas, Saint (A.D. 300's), is one of the most popular saints of the Christian church. He is the patron saint of sailors, travelers, bakers, merchants, and especially children. Little is known about his life except that he was Bishop of Myra in Lycia, on the coast of Asia Minor. According to tradition, he was born in Lycia. Some legends say he made a pilgrimage as a boy to Egypt and Palestine, that he was imprisoned during Diocletian's persecution, and released under Constantine the Great. In addition, legends say Nicholas attended the Council of Nicaea in 325. Numerous miracles were credited to him.

Much of Europe still observes December 5, St. Nicholas Eve, and December 6, the supposed day of Saint Nicholas's death, as special holidays. For example, in Germany, Switzerland, the Netherlands, and Belgium, men in bishops' robes pose as Saint Nicholas. They visit children, examine them on their prayers, urge them to be good, and give them gifts. This custom probably originated in the legend that Saint Nicholas gave gold to each of three girls who did not have dowries and so could not get married.

Saint Nicholas evolved into Father Christmas in Germany and Protestant northern Europe. Dutch immigrants brought the tradition of "the visit of Saint Nicholas" to America. The Dutch settlers and their English neighbors transformed Nicholas into the kind and jolly patron of American Christmas. The name Santa Claus comes from Sinterklaas, which is Dutch for Saint Nicholas.

Nicholas of Cusa, KOO suh (1401-1464), was a German theologian, scholar, and statesman. Nicholas wrote extensively on philosophy, theology, mathematics, and astronomy. In his most famous work, On Learned Ignorance (1440), Nicholas argued that reason is inadequate to determine truth. In his writings on astronomy, Nicholas suggested that the earth is in motion and is not the center of the universe. Thus, he was a forerunner of the theories developed in the 1500's by the Polish astronomer Nicolaus Copernicus.

Nicholas was born at Kues, Germany, near Trier. The Latin form of Kues is Cusa. In 1437, with the approval of Pope Eugene IV, Nicholas traveled to Constantinople to arrange a meeting between Eastern and Western church officials to discuss reunification. In 1438, Nicholas went to Germany to help regain for the papacy the allegiance of the Holy Roman Empire. This mission ended successfully in 1448 with the signing of the Concordat of Vienna. Pope Nicholas V made Nicholas a cardinal in 1449. In 1450, Nicholas became bishop of Brixen (now Bressanone), Italy. William J. Courtenay

Nichols, Mike (1931- ), is a famous German-born director known for his work in motion pictures and on the stage. Nichols won an Academy Award for directing The Graduate (1967), his second movie. His other films include Who's Afraid of Virginia Woolf? (1969), Catch-22 (1970), Carnal Knowledge (1971), Silkwood (1983),

Brienne Bros.
Nicholson, Ben (1984-1982), was an English artist noted for his abstract paintings. Nicholson's most valued artistic contribution is the relief, a three-dimensional abstract picture created by cutting, carving, and painting flat boards. In his reliefs, Nicholson explored the interaction of form and light. His early reliefs are painted white. His later reliefs incorporate subtle color and texture.

Nicholson was born in Denham, near London, on April 10, 1894. His father was Sir William Nicholson (1872-1949), also an artist. Ben Nicholson's early works were charming and realistic decorative paintings. He also painted still lifes that demonstrate the influence of the French artist Paul Cézanne and the Cubism movement. Nicholson died on Feb. 6, 1982.

Pamela A. Wisniewski

Nicholson, Jack (1937- ), is an American motion-picture actor and director. He often plays a cocky, rude outsider or free-spirited individualist who rejects conventional society. Nicholson has won three Academy Awards. He won the 1975 best actor award for One Flew Over the Cuckoo's Nest and the 1997 award for As Good As It Gets. He won the 1983 award as best supporting actor for Terms of Endearment.

Rachel Gallagher

Nickel is a white metallic chemical element used in alloys. Nickel is magnetic, takes a high polish, and does not tarnish easily or rust. It can be hammered into thin sheets or drawn into wires. One pound (0.4 kilogram) of pure nickel could be drawn into a wire 80 miles (130 kilometers) long. The Chinese used an alloy of nickel more than 2,000 years ago. Pure nickel was first isolated in 1751 by the Swedish scientist Axel Cronstedt.

Nickel's atomic number (number of protons in its nucleus) is 28. Its relative atomic mass is 58.6934. An element's relative atomic mass equals its mass (amount of matter) divided by \( \frac{1}{12} \) of the mass of carbon 12, the most abundant form of carbon. Nickel's chemical symbol is Ni.

**Industrial uses.** Nickel is used in structural work and in electroplating chiefly because it resists corrosion. Printing plates electroplated with nickel withstand hard use (see Electroplating). Nickel peroxide, a nickel compound, forms the active material of the positive electrode in the Edison storage battery. Nickel is also used in the nickel-cadmium storage battery (see Battery).

An important use for nickel is to promote certain chemical reactions by catalysis (see Catalysis). The nickel itself is not changed in the process and can be used repeatedly. Nickel is used as a catalyst in a process called hydrogenation to produce solid vegetable oils for cooking. See Hydrogenation.

**Nickel-iron alloys.** Perhaps the largest use for nickel is as an additive to cast iron and steel. It makes iron more ductile (easily formed) and increases its resistance to corrosion. Nickel also makes steel more resistant to impact. Manufacturers often use steel alloyed with nickel to make armor plate and machine parts.

**Invar** is an alloy of nickel, iron, and other metals. It is valued for meter scales and for pendulum rods. Invar expands or contracts little as its temperature changes.

**Monel metal** is an alloy of nickel and copper used in sheet-metal work. It has an especially high resistance to corrosion. See Monel metal.

**Nickel silver,** also called German silver, is a nickel alloy used in tableware. See Nickel silver.

**Mining nickel.** The chief mineral ore of nickel is pentlandite, a mixture of sulfur, iron, and nickel. Other nickel ores include millerite and niccolite.

Russia is the world's leading producer of nickel. It produces about a fourth of the world total. Australia, Canada, Indonesia, and New Caledonia are also important nickel-producing areas. **Robert J. Doedens**

**Nickel** is the common name for a U.S. copper-nickel coin. It is worth five cents, and its official name is the five-cent piece. The current Jefferson nickel has been minted since 1938. It has a profile of Thomas Jefferson on the obverse (front), and a picture of Monticello, Jefferson's home, on the reverse (back). A nickel with an Indian head on the reverse and a buffalo on the reverse was minted from 1913 through 1938. Nickels made from 1883 through 1912 had a head of Liberty on the obverse and a V (Roman numeral five) on the reverse. The earliest U.S. five-cent pieces had a shield on the obverse and
The U.S. nickel shows Thomas Jefferson and Monticello.

Nickel silver is an alloy of copper, nickel, and zinc. It is also called German silver because it was first made in Hildburghausen, Germany. It is a yellowish metal that is harder than silver. Nickel silver tarnishes easily, but it takes a good polish. Much of the silverware used today is made of nickel silver plated with real silver. It looks like solid silver when new, but the plate wears off with use. Vinegar and strong salt solutions may combine with nickel silver to form substances that can make people ill. Silver-plated tableware should not be used with these types of liquids after the silver plate has worn off. See also Alloy, Melvin Bernstein

Nickelodeon. See Motion picture (The history of motion pictures; picture)

Jack William Nicklaus was born in Columbus, Ohio. He was nicknamed the “Golden Bear” for his blond hair. His first professional tournament victory came in 1962 when he defeated Arnold Palmer in a playoff for the 1962 U.S. Open championship. Nicklaus has also designed a number of golf courses. Marino A. Parascenzo

See also Golf (picture).

Nicolot, nɪˈkɔːlət, nɪˈkoʊl ət or nɪˈkɔːl ət LAY, Jean, zhahn (1598-1642), also spelled Nicollet, was a French explorer, trader, and interpreter. He was the first European to enter Lake Michigan and travel in what is now Wisconsin, adding to French knowledge of North America. Nicollet was born Jean Nicollet de Belleborne in Châlons-sur-Marne, France. He traveled to North America in 1618 with Samuel de Champlain, a French explorer. For two years, Nicollet lived among Algonquin Indians of Alumette Island on the Ottawa River, in present-day Quebec. In 1620, Champlain sent Nicollet to Lake Nipissing, what is now Ontario. Nicollet traded there until 1629. In 1634, Nicollet traveled north on Lake Huron and then west to Lake Michigan. He established friendly relations with Winnebago Indians who lived along Lake Michigan’s Green Bay. But he failed to achieve the other goal of his voyage—to find a route to Asia. He also traveled up the Fox River and to the Illinois River (both in present-day Illinois). Nicollet returned to Quebec in 1635 and settled in Trois-Rivières in 1637, where he lived quietly until his death. D. Peter MacLeod

Nicosia, nɪˈkɔːs iə (pop. 163,700), is the capital and largest city of Cyprus, an island republic in the Mediterranean Sea. For its location, see Cyprus (map). The city serves as the island’s business center and as a trade center in the Mesaoria Plain. Goods produced there include almonds, fruit, olive oil, wheat, and wine.

In 1974, Turkish troops invaded Cyprus. Nicosia was divided into a Turkish Cypriot section and a Greek Cypriot section. The island’s main government offices are located in the southern section. Theofanis G. Stavrou

Nicotine is a substance found in small amounts in the leaves, roots, and seeds of the tobacco plant. It can also be made synthetically. Chemists classify nicotine as an alkaloid (see Alkaloids). Pure nicotine is extremely poisonous. A small amount can cause rapid but weak pulse, vomiting, extreme weakness, or even collapse or death.

Smoking tobaccos generally contain between 1 percent and 2 percent nicotine. A smoker takes in about 0.05 milligram to 2 milligrams of nicotine per cigarette. The nicotine is quickly absorbed into the blood and reaches the brain within eight seconds after inhalation.

Nicotine is the ingredient in tobacco to which people become addicted. Most physicians agree that use of tobacco is unhealthy. In 1956, the United States Food and Drug Administration (FDA) finalized rules to prevent people under the age of 18 from using tobacco. The rules are based on the agency’s finding that cigarettes and chewing tobacco are “delivery devices” for nicotine. In 2000, however, the Supreme Court of the United States ruled that the FDA does not have the authority to regulate tobacco products. Barbara M. Bayer

Niebuhr, NEE boor, H. Richard (1894-1962), was an influential Protestant theologian. He was an authority on Christian ethics and religion in the United States.

In The Social Sources of Denominationalism (1929), Niebuhr argued that race and social class were important in determining the religious affiliation of most Americans. In The Kingdom of God in America (1937) and Christ and Culture (1951), Niebuhr showed how Christian principles have helped shape American culture and warned Christians not to allow their values to be overly influenced by the society in which they lived. Many of Niebuhr’s other writings focused on the need for religious people to integrate their beliefs with their involvement in daily life.

Helmut Richard Niebuhr was born in Wright City, Missouri. His brother, Reinhold Niebuhr, was also a Protestant theologian. Charles H. Lippy

Niebuhr, NEE boor, Reinhold (1892-1971), was a prominent American theologian. He was known for his writings on ethics.

Karl Paul Reinhold Niebuhr was born in Wright City, Missouri. After graduating from Yale Divinity School in 1915, he was a pastor at an Evangelical church in Detroit for 13 years. Niebuhr believed that Christian ethical teaching and socialism could offer solutions to social conflicts. He also was a pacifist.
In 1928, Niebuhr became a professor of the philosophy of religion at Union Theological Seminary in New York City. About this time, he began to abandon his earlier views in favor of a new approach called *Christian Realism*. According to this philosophy, an ideal society will always be beyond humanity's grasp, but moral individuals should still work for social justice. In doing so, Christians should apply moral principles in a way that is flexible enough to account for certain situations. For example, the Christian Realist approach led Niebuhr to abandon pacifism when the Nazis came to power in Germany. Niebuhr believed the Nazis were a symbol of an evil greater than the evil of war.

Niebuhr wrote several books on ethics. His most influential work is the two-volume *Nature and Destiny of Man* (1941, 1943). Niebuhr's brother, H. Richard Niebuhr, was also a prominent theologian.  

Charles H. Lippy

**Nielsen, NEEL suhn, Carl August** (1865-1931), was one of Denmark's greatest composers. His music was not widely performed during his lifetime, but it has become internationally known since his death.

Nielsen wrote in the traditional forms of the 1800's. His early works reflect an influence of the musical styles of Johannes Brahms and Franz Liszt. However, Nielsen's own style grew steadily, and he eventually developed a more modern musical language, especially in his use of more dissonant harmonies. Nielsen's compositions include six symphonies, symphonic poems for orchestra, and concertos for clarinet, flute, and violin. He also wrote chamber music, 10 cantatas, and works for both piano and organ. One of his last major compositions is *Piano Music for Young and Old* (1930), a set of 24 pieces in all keys. Nielsen was born near Odense.

Daniel T. Polotske

**Niemeyer, NEE my ohr, Oscar** (1907- ), is a Brazilian architect. He is best known as the designer of the principal buildings of Brasília, the Brazilian capital (see Brasília). Niemeyer often uses primary forms for entire buildings, and in repetitious architectural elements. He has said that his designs are inspired by Brazilian climatic and social conditions, and the nation's colonial baroque art heritage.

Niemeyer was born in Rio de Janeiro. His early work was influenced by brief contact with the architect Le Corbusier. An example of this work is the Ministry of Education (1937-1943) in Rio de Janeiro. It is shaped like a slab, with windows set deeply into the concrete building to provide sun shades. During the early 1940's, Niemeyer served as chief architect for Pampulha, a new residential suburb near Belo Horizonte. Among his later works is the headquarters of the French Communist Party (1965-1980) in Paris.

Dennis Donner

**Niépce, nyehps, Joseph Nicéphore, zhoh ZEHF nee say FAWR** (1765-1833), a French scientist, invented the first photographic technique, *heliotherapy*. Niépce began experimenting in 1816. He succeeded in making a crude photograph of a courtyard in 1826. He sensitized a metal plate with bitumen and exposed it eight hours. This plate, the world's first photograph, is in the Germ- sheim Collection at the University of Texas at Austin (see Photography [History; picture]). Niépce also produced photogravure plates from engravings and pioneered photomechanical reduction methods.

In 1829, Niépce became the partner of L. J. M. Da- guerre, who based his researches for his daguerreotyp process on Niépce's earlier technique of heliography (see Daguerrre, Louis J. M.). Niépce was born in Chalon-sur- Saône.

Richard Kuhns

**Nietzsche, NEE chuh, Friedrich**, *FREE drikeh* (1844-1900), was a German philosopher and classical scholar. He deeply influenced many philosophers, artists, and psychologists of the 1900's.

**Classical scholarship.** Nietzsche's first book was *The Birth of Tragedy* (1872). It presented a new theory of the origins of classical Greek culture. Nietzsche believed that Greek culture could best be understood as resulting from a conflict between two basic human drives, the *Apollonian* and the *Dionysian*. The Apollonian was represented by Apollo, the god of the sun. The Dionysian was represented by Dionysus, the god of wine and intoxication.

The Apollonian is a drive to create clarity and order, and is a desire for a world in which everything possesses a clear identity and can be distinguished from other things. The Apollonian tendency finds expression in the visual arts, where each form stands out clearly from other forms. Nietzsche argued that, in reality, the world lacks any clear distinctions, that it is confused, chaotic, and cruel. The Apollonian drive tries to redeem the horrors of the real world by giving it the illusion of order and beauty, thus making it tolerable.

The Dionysian is a drive that tries to rip apart Apollonian illusions and reveal the reality that lies behind them. This revelation takes place only in special states of ecstasy or religious frenzy induced by drinking, wild music, and sexual license.

**Nietzsche and religion.** Nietzsche was a severe critic of religion, especially Christianity. In *Thus Spake Zarathustra* (1883 to 1885), he proclaimed that "God is dead." This was his dramatic way of saying that most

![Messerschmidt: The Presidential Offices](picture.jpg)
people no longer believed in God. Thus, religion could no longer serve as the foundation for moral values.

Nietzsche believed that the time had come to examine traditional values critically. In *Beyond Good and Evil* (1886) and *The Genealogy of Morals* (1887), he examined the origins of our moral systems. He argued that the warriors who dominated earlier societies had defined their own strength as "good" and the weakness of the common people they dominated as "bad." Nietzsche called this "master morality" because it represented the values of the masters.

Later, the priests and common people, who wanted to take power, defined their own weakness and humility as "good." They called the aggressive strength of the warriors "evil." Nietzsche identified these values, which he called "slave morality," with the values of the Judeo-Christian tradition that dominates Western culture. He criticized these values as being expressions of the fear and resentment of the weak against the strong.

**Psychological ideas.** Nietzsche’s major psychological theory states that all human behavior is inspired by a ‘will to power.’ He wanted to disprove and replace a common prevalent psychological theory that was known as hedonism. Hedonism holds that human behavior is inspired by a desire to experience pleasure and avoid pain. Nietzsche argued that people are frequently willing to increase their pain, strain, or tension to accomplish tasks that allow them to feel power, competence, or strength.

Nietzsche did not mean that people wanted only to dominate each other, nor that they were only interested in physical or political power. He wrote that we also want to gain power over our unruly drives and instincts. He thought that the self-control exhibited by artists and people who practice self-denial for religious reasons was actually a higher form of power than the physical bullying of the weak by the strong.

Nietzsche’s ideal was the overman or superman, a passionate individual who learns to control his or her passions and use them in a creative manner. This superior human being channels the energy of instinctual drives into higher, more creative, and less objectionable forms. Nietzsche believed that such "sublimation" of energy is far more valuable than the suppression of the instincts urged by Christianity and other religions.

**His life.** Nietzsche was born in Röcken, Saxony, near present-day Leipzig, Germany. He was a professor of classics at the University of Basel in Switzerland from 1868 to 1878, when he retired because of poor health. He then devoted himself to writing. In 1889, Nietzsche suffered a mental breakdown from which he never recovered. Nietzsche is often wrongly considered a racist, anti-Semitic, and forerunner of Nazism. These charges are largely the result of distortions of his ideas by his sister, Elisabeth, and by Nazi propagandists after his death. *van Soll

**Niger,** *Ny jarh,* is a large, landlocked country in west Africa. Barren desert and mountains cover most of northern Niger. A grassy, thinly wooded plain extends along the southern border. The country, officially called the Republic of Niger, takes its name from the Niger River, which flows through its southwest corner. Niamey is Niger's capital and largest city.

The people of Niger belong to many different ethnic groups, each with its own language and customs. Almost all the people are black Africans, and a large majority are Muslims. Most people work as farmers and live in the south, where water and land are available.

Niger became an independent nation in 1960. France had ruled it for about 60 years before independence.

**Government.** The president is the most powerful official in the government. The president appoints a prime minister and other members of the cabinet, determines their responsibilities, and may end their appointments at any time. The president is elected by the people to a five-year term and is forbidden to serve more than two terms.

The National Assembly is responsible for making Niger’s laws. The 83 members of the National Assembly are elected for five-year terms. Major political parties in Niger include the National Movement of the Development Society (MNSD) and the Democratic and Social Convention (CDS). The Supreme Court is Niger’s highest court.

**People.** The people of Niger are called *Nigeriens* (nee ZHEH reh uhhn). About 98 percent of Niger’s people are...
Facts in brief

Capital: Niamey.
Official language: French.
Area: 489,191 mi² (1,267,000 km²). Greatest distances—east-west, 1,100 mi (1,770 km); north-south, 825 mi (1,328 km).
Elevation: Highest—Mount Greboun, 6,378 ft (1,944 m) above sea level.
Population: Estimated 2002 population—11,395,000; population density, 23 per mi² (9 per km²); distribution, 83 percent rural, 17 percent urban. 1988 census—7,248,100.
Chief products: Agriculture—beans, cassava, cotton, hides and skins, livestock, millet, peanuts, peas, rice, sorghum. Mining—uranium, natron, phosphate, salt, tin.
Flag: Horizontal stripes of orange, white, and green; an orange circle on the white stripe. See Flag (picture: Flags of Africa).
Money: Basic unit—franc. One hundred centimes equal one franc.

black Africans. Nonblack minorities include a local white ethnic group called the Tuareg, whites from other countries, and Asians.

The major black ethnic groups in Niger include the Hausa, Djerma-Songhai, Kanuri, and Fulani. The Hausa make up about half of the population of Niger. They live mainly in the south and work as farmers. Between a fourth and a fifth of the people are members of the Djerma-Songhai ethnic group. The Djerma-Songhai are farmers and live in the southwestern corner of the country, along the Niger River. The Kanuri make up about 5 percent of the population. They farm the rich land in southeast Niger.

Many of the Fulani and the Tuareg are nomadic (traveling) people who raise livestock for food. Together they make up more than 10 percent of the population. During the rainy season, which lasts from July through September, these two groups live in the barren desert country of northern Niger. In dry months, they travel south in search of water and pastureland.

Most of the people who live in Niger's rural areas raise crops and livestock for food and for export. Some Nigerians who live near the Niger River or Lake Chad fish for a living. The nomadic groups raise camels, cattle, goats, and sheep. In the late 1960's and early 1970's, and again in the early 1980's, severe droughts led to the deaths of many of the nomads' animals. As a result, many nomads were forced to become farmers or move to urban areas.

Niamey, Niger's capital, is its largest city by far. Other large cities include Agadez (Agades), Maradi, Tahoua, and Zinder. Most urban workers in Niger have jobs in the government and other services, or in business.

Houses in rural Niger are built according to the traditions of the ethnic groups. The Hausa live in crowded villages and towns, in houses built of sun-dried mud bricks. The nomadic Tuareg live in tents made of skins or mats. The nomadic Fulani build houses out of straw and branches, and must construct new homes every time they move. The Nigerien government has built low-cost single-family houses in Niamey. Many buildings in Niamey combine Western and African designs.

Nigerians eat mainly grains and dairy products. Several popular dishes are made with millet and sorghum. The grains are often cooked into a porridge and served with a sauce. The nomadic Fulani and Tuareg live mainly on milk products from their herds. They also trade these products for grains and vegetables.

Most Nigerien women wear long, wrap-around skirts with short blouses and sandals. Men may wear pants or knee-length shorts with loose shirts or robes. Tuareg men wear turbans with veils. The Fulani and Tuareg, who travel in desert areas, wear long, loose robes for protection from the sun.

Education in Niger is free, but many areas do not have schools. The government operates the public schools. Many places have Quranic schools, which teach Muslim religious knowledge. A system of "tent schools" serves the nomadic groups in the north. When a group moves, the school moves with it. Most of Niger's adults cannot read or write. For the country's literacy rate, see Literacy (table: Literacy rates).

French is the official language of Niger and is widely used in the schools. However, most Nigeriens commonly speak the language of their ethnic group, instead of French. More than 85 percent of the population understand the Hausa language, which serves as the language of trade. The language of the Djerma-Songhai ranks as the second most widely spoken language. Some Nigeriens speak Arabic.

About 90 percent of Nigeriens are Muslims. A small percentage of urban dwellers are Christians. Some rural Nigeriens practice traditional African religions.

The ethnic groups in Niger have produced many kinds of crafts, music, dance, and art. Craftworkers make gold and silver jewelry, pottery, leatherwork, cloth, and wood carvings. People in both urban and rural areas enjoy traditional African styles of music. Popular forms of recreation include cycling, basketball, and soccer.

Land and climate. Niger has an area of 489,191 square miles (1,267,000 square kilometers). Sandy plateaus and desert cover the northern two-thirds of Niger. In the center of this region, a large area of mountain

Hausa women in Niger work in the grain fields near their village. The Hausa people make up the country's largest ethnic group. Most Hausa make their living by farming.
ranges called the Air Mountains rises above the flat landscape. These mountains include the highest peak in Niger, Mount Gréboun, which stands 6,378 feet (1,944 meters) above sea level. Less than 7 inches (17.5 centimeters) of rain falls each year in the mountains. The surrounding desert receives even less rain. Temperatures in the area can reach as high as 122 °F (50 °C).

Niger's most productive zone for herding animals and growing crops is the savanna, a grassy, thinly wooded plain in the south. The savanna extends from the Niger River in the west, along Niger's southern border, to Lake Chad in the east. It is one of the hottest places in the world, with average daily temperatures in Niamey reaching 95 ° to 100 °F (35 ° to 38 °C). Most of Niger's rain falls in the savanna area. The city of Zinder receives about 22 inches (55 centimeters) annually.

Niger is a landlocked nation, with no outlet to the sea. The Niger River flows for about 350 miles (563 kilometers) across the southwest corner of Niger. The river floods each January and February and provides irrigation water for growing crops along its banks. Part of Lake Chad lies in southeastern Niger.

Niger's plant and animal life vary from north to south. Few plants grow in the desert, except near oases, where the date palm tree is common. Such wild animals as foxes, ostriches, and gazelles and other antelope live in the north. Palm, mahogany, kapok, acacia, and baobab trees grow in the south. Wild animals in the south include elephants, wart hogs, baboons, giraffes, and crocodiles.

**Economy.** Niger is one of the poorest countries in the world. Only 3 percent of its land is used to grow crops, and it has few natural resources. Droughts have devastated the economy at various times, causing sharp reductions in crop and livestock production.

Niger's most important economic resource is uranium. The country is a major producer and exporter of uranium. Other minerals produced in Niger include iron ore, natron, phosphate, salt, and tin.

About 90 percent of Niger's people live by farming and herding. Niger's agricultural exports include cotton, peanuts, livestock, meat, and hides. Such crops as beans, cassava, millet, peas, rice, and sorghum are grown for food. Farmers raise cattle, oxen, goats, and camels for food, export, and transport.

Poor transportation has hampered economic development in Niger. The country has no railroads, and most of its roads are not paved. Few Nigerians own an automobile. Trucks carry freight, and people get around by buses or on foot. Niamey has an international airport.

Niger has one daily newspaper. The government controls all communications media in the country.

**History.** About A.D. 1000, Tuareg people began moving south from the middle of the Sahara into what is now Niger. They eventually controlled the trade routes across the desert and south to the coast. In the 1400s, a Tuareg empire grew up around the city of Agadez.

The Songhai Empire became powerful in the 1400s. Its capital was Gao, in what is now Mali. During the 1500s, the empire conquered the Tuareg at Agadez, and controlled much of central and western Niger. In 1591, an army from Morocco captured Gao, and the empire collapsed. See Africa (Kingdoms in western Africa).

Hamani Diori was elected Niger's first president. In the late 1960s and early 1970s, a severe drought struck Niger, causing widespread food shortages and other problems. In 1974, a group of army officers held by Seyni Kountché overthrew Diori's government. Kountché became president of the Supreme Council (formerly called the Supreme Military Council), which held all governing power. Kountché died in 1987, and the council chose Colonel Ali Saibou to succeed him. Niger's economy suffered during the 1980s because worldwide prices of uranium declined.

In 1992, Niger adopted a multiparty political system. Mahamane Ousmane was elected president in 1993. In January 1996, a military coup led by General Ibrahim Bare Mainassara overthrew the government. Mainassara named himself head of state. In May, voters approved a new constitution supported by Mainassara. Mainassara won a presidential election held in July, but opposition leaders claimed the election was fraudulent. In April 1999, Mainassara was assassinated, and military leaders took control of the government. In November, Niger held elections to restore civilian rule. The voters elected Mamadou Tandja as president.

**Niger River.** *Ny juh* is the third longest river in Africa. Only the Nile and Congo rivers are longer. The Niger flows about 2,600 miles (4,180 kilometers) in western Africa. It carries more water than any other African river except the Congo. The Niger drains about 580,000 square miles (1,500,000 square kilometers) of land.

The Niger begins in the highlands of southern Guinea, near Guinea's border with Sierra Leone. The river then flows northeast into Mali, where it turns southeastward. After leaving Mali, the river cuts through the southwestern part of Niger and the northern tip of Benin. It then flows through western Nigeria, where it is joined by its main tributary, the Benue River. Near the coast of southern Nigeria, the Niger flows through a large delta region and empties into the Gulf of Guinea, an arm of the Atlantic Ocean.

Fishing and the transportation of passengers and freight are important activities on the Niger. Boats can navigate the river for about 1,000 miles (1,600 kilometers) in Mali and about 400 miles (640 kilometers) in Nigeria the year around. Rapids, waterfalls, and other obstacles prevent navigation on other parts of the Niger.

The delta region of the Niger has major deposits of petroleum. The Niger is an important source of hydroelectric power. The Kainji Dam in Nigeria is one of the largest power projects on the river. The dam, which holds back the Niger to form Kainji Lake, produces much of Nigeria's electricity.

The Scottish explorer Mungo Park became the first European to explore the course of the Niger. Park led expeditions on the river in 1796 and 1797 and in 1805 and 1806. See also Africa (political map).
Nigeria

Nigeria, ny JHHR ee ah, a nation on the west coast of Africa, has more people than any other country in Africa. Nigeria ranks as one of the largest countries in the world.

Nigeria is a land of great variety. It has hot, rainy swamplands; dry, sandy areas; grassy plains; and tropical forests. High plateaus and rocky mountains rise in various parts of the country. The population of Nigeria consists of more than 250 ethnic (cultural) groups. Most of the country's people live in rural areas. Nigeria also has several large, crowded cities. Lagos is the chief commercial center. Abuja is the capital of the country.

Most Nigerians earn their livelihood by farming, fishing, or herding. The country is a leading producer of cacao, peanuts, and other crops. In addition, Nigeria has mineral resources, including large deposits of petroleum. Since the late 1960's, profits from Nigeria's oil industry have brought new wealth to the nation. Nigeria has used this wealth to develop new industry, improve its educational system, and modernize its agriculture.

A number of ancient kingdoms developed in the area that is now Nigeria hundreds of years ago. Some of the kingdoms became important cultural and trade centers. The United Kingdom gained control of Nigeria in the late 1800's and the early 1900's. Nigeria was a British colony and protectorate until 1960, when it gained independence.

Women harvest peanuts, one of Nigeria's leading crops, at a farm in the northern part of the country. Nigeria has more people than any other country in Africa. Most Nigerians live in rural areas and earn their livelihood by farming, fishing, or herding.

Ebere Onwudiwe, the contributor of this article, is Professor of Political Science at Central State University in Ohio.

Government

Military leaders controlled Nigeria's government from 1966 to 1979 and from 1983 to 1999. Civilian rule was restored in 1999, and a new constitution was adopted.

National government. A president heads the government of Nigeria. The president is elected by the people to a four-year term and cannot serve more than two terms. A vice president and Cabinet assist the president in handling the day-to-day operations of the government. The people elect the vice president. The president appoints members of the Cabinet with the approval of the Senate.

The National Assembly is Nigeria's legislature. The Assembly consists of the 360-member House of Representatives and the 109-member Senate. The people elect representatives and senators to four-year terms. All Ni-
gerian citizens who are 18 years of age or older may vote.

Local government. Nigeria is divided into 36 states and the Federal Capital Territory of Abuja. Each state is governed by a House of Assembly and a governor. Assembly members and the governor are elected by the people to four-year terms. Nigeria's 36 states are divided into over 750 local government areas. Elected local government councils administer these areas.

Courts. The Supreme Court is the highest court in Nigeria. The country's judicial system also includes federal courts of appeal, the Federal High Court, and state high courts.

Nigeria has a number of religious courts. These courts have traditionally ruled only on questions of Islamic personal law for people who are practicing Muslims. The highest such court is the Shari'a Court of Appeal in Abuja. In the early 2000's, a number of largely Muslim northern states adopted Shari'a (also spelled Shari'ah), which is the body of Islamic law, as the basis of their legal codes. As a result, Shari'a is now applied to both civil and criminal cases in those states.

Armed forces. About 70,000 people serve in the Nigerian Army. The country also has a small navy and air force, and a federal police force. All military service is voluntary.

People

Ancestry. Almost all Nigerians are black Africans. The country has more than 250 ethnic groups. These groups differ from one another in language and in some of their customs and traditions. The three largest ethnic groups are, in order of size, the Hausa, the Yoruba, and the Igbo (also spelled Ibo). These three ethnic groups account for about three-fifths of the total population of Nigeria.

The Hausa people live primarily in northern Nigeria and in the neighboring countries of Niger and Chad. Most of them are farmers, and many also are craftworkers and traders. The Hausa have lived in the area for more than a thousand years. During the 1200's, the Fulani, a people who originally came from what are now Senegal and Gambia, began to settle in the Hausa territory. The Fulani took control of the region during the early 1800's. The two peoples intermixed so much that the group is sometimes called the Hausa-Fulani.

The Yoruba live mainly in the southwestern part of the country and in Benin and Togo, two nations that lie to the west of Nigeria. Many of the Yoruba live in cities and farm the land in the surrounding countryside. Several Yoruba cities, including Lagos, were founded hundreds of years ago.

The Igbo form a majority of the population in southeastern Nigeria. In addition, a large number of Igbo live in other areas of the country. During the period of British rule in the 1900's, many Igbo accepted Western education and ways of life more quickly than the other Nigerian ethnic groups. The Igbo were also more willing to travel. As a result, the Igbo held many important positions in business and government during the period of colonial rule.

Other leading ethnic groups in the country include the Nupe and Tiv of central Nigeria; the Edo, Urhobo, and Isokiri of the Edo and Delta states; the Ijaw of the

Abuja, officially the capital of Nigeria since 1991, lies in a hilly region in the central part of the country. Aso Rock, background, and other huge rock formations stand in or near the city.

Nigeria's flag was adopted in 1960. The green represents agriculture, and the white symbolizes unity and peace.

Coat of arms. The design on the shield stands for Nigeria's fertile soil and main rivers, the Niger and the Benue.

Nigeria, a large country in West Africa, lies on the Gulf of Guinea, just north of the equator.
Rivers state; the Efik and Ibibio of the Cross River State; and the Kanuri of northeastern Nigeria. The Kanuri trace their ancestry back to the ancient Kanem empire, which began during the A.D. 700’s.

Languages. English is the official language of Nigeria and is taught in schools throughout the country. However, English is not the country’s most commonly used language. Each of the more than 250 ethnic groups that live in Nigeria has its own distinct language. The three most widely used languages are those of the three largest ethnic groups—Hausa, Yoruba, and Igbo.

A majority of the people of Nigeria speak more than one language. They may use the language of their ethnic group on most occasions and speak English or another language at other times. In addition, Nigerians who are Muslims use Arabic while taking part in various religious activities.

Way of life. Most of Nigeria’s people live in rural areas. Most homes in rural Nigeria are made of grass, dried mud, or wood and have roofs of asbestos cement sheets, corrugated metal, or thatch. A typical village consists of several compounds (clusters of houses). A group of related families lives in each compound. Well-to-do city dwellers in Nigeria live in modern houses or apartment buildings. The cities also have slums, where people live in mud huts that line unpaved streets. Overcrowding has become a serious problem in many Nigerian cities since the 1960’s, when increasing numbers of people began moving from rural to urban areas in search of jobs.

In the cities, many Nigerians wear Western-style clothing. But other city dwellers and most people in rural areas wear traditional clothing. Traditional garments for men and women in Nigeria include long, loose robes made of white or brightly colored fabrics. The men may also wear short, full jackets with shorts or rousers. Small round caps are popular head coverings for men, and Nigerian women often wear scarves tied like turbans.

The chief foods of Nigeria include yams, corn, rice, and beans. The people also eat plantains (a kind of banana) and the roots of the cassava plant. Nigerian food is often cooked in palm oil or peanut oil, and it may be highly seasoned with red peppers. Some Nigerian meals feature beef, chicken, fish, or lamb. But in general, most Nigerians eat little meat. Popular beverages in Nigeria include beer and a wine that is made from the sap of palm trees. Some city dwellers also drink coffee and tea. Nigerian Muslims who obey the laws of Islam may not drink alcoholic beverages.

Religion. About half the people of Nigeria are Muslims. They make up the majority of the population in the north. Nearly 40 percent of the people are Christians. They live mainly in southern and central parts of Nigeria. Many Nigerians, especially in the rural areas, practice traditional religions based on the worship of many gods and spirits. People throughout the country may combine Christian or Muslim religious practices with traditional beliefs.

Education. About half of Nigeria’s adults can read and write. For the country’s literacy rate, see Literacy (table: Literacy rates). Nigeria does not have enough schools or teachers to provide an education for all school-age children, and laws do not require school att-

Lagos, which served as Nigeria’s capital from 1914 to 1991, is the nation’s chief port and commercial and manufacturing center. Downtown Lagos has a number of tall, modern buildings.

A typical village house in Nigeria is made of grass, dried mud, or wood and has a roof of asbestos cement sheets, corrugated metal, or thatch. Most villages consist of clusters of houses.

Nigerian Muslims dressed in traditional costumes take part in a durbar (parade) at a festival in Katsina in northern Nigeria. About half the people of Nigeria are Muslims.
Music and dance are popular forms of entertainment in Nigeria. These Hausa musicians and dancers from Kano in northern Nigeria are performing in Lagos.

tendance. About 15 million children attend elementary schools in Nigeria. About 3½ million students attend secondary schools. Nigeria has about 30 universities. The largest is Ahmadu Bello University, in Zaria.

Recreation. People in both urban and rural areas of Nigeria enjoy performances of traditional songs and dances. Motion pictures attract many people in the large cities, where radio and television are also popular. Soccer ranks as the favorite sport in Nigeria. Art festivals and special sports contests are held in many parts of the country.

The arts. Nigeria is famous for the variety and quality of its art. The art of Nigeria and other African countries has influenced art movements in many other parts of the world. For example, traditional African sculpture influenced Pablo Picasso and other modern Western artists.

The oldest known African sculptures are terra-cotta (clay) figures created by the Nok civilization in central Nigeria as early as 500 B.C. Other famous traditional sculptures include the bronze and brass figures of Benin and Ife, and the woodcarvings of the Yoruba people. Various peoples who live in the forest areas of Nigeria are known for their elaborately carved wooden masks. Most of the traditional Nigerian painting is done on sculptures and textiles, or as body decoration.

Nigerian music often features drums, xylophones, and various string and wind instruments. Dance and dramatic performances are popular forms of entertainment in Nigeria. Many of these performances portray themes from folk stories or topics related to the everyday life of the people.

Most of Nigeria’s traditional literature is oral, rather than written. Popular forms of such literature include chants, folk stories, proverbs, and riddles. During the mid-1900’s, many Nigerian authors began to write novels, stories, and poetry. These works were written in English and in local languages. In 1986, Nigerian playwright, poet, and novelist Wole Soyinka became the first African writer to win the Nobel Prize in literature.

The land and climate

Land regions. Nigeria covers 356,669 square miles (923,768 square kilometers). It can be divided into 10 land regions. They are: (1) the Sokoto Plains, (2) the Chad Basin, (3) the Northern High Plains, (4) the Jos Plateau, (5) the Niger-Benue River Valley, (6) the Western Uplands, (7) the Eastern Highlands, (8) the Southwestern Plains, (9) the Southeastern Lowlands, and (10) the Niger Delta.

The Sokoto Plains occupy the northernmost corner of Nigeria. Several rivers flow across the flat, low-lying plains and flood the area during the rainy season. The floodwaters deposit fertile soil that allows farmers to grow various crops in the area. But the floods also occasionally destroy homes and farms.

The Chad Basin extends across northeastern Nigeria, south and west of Lake Chad. Sandy ridges cut across parts of the low-lying basin. During the rainy season, parts of the region become swampy. But long dry spells occasionally cause severe droughts in the region. Short grasses and thinly scattered trees grow in the Chad Basin.

The Northern High Plains cover almost a fifth of Nigeria’s total area. They consist largely of flat grasslands, with a few hills and granite ridges. Most of the plains area has an elevation of about 2,500 feet (762 meters) above sea level.

Several branches of the Niger River have their source in the Northern High Plains. These branches include the Gongola, Sokoto, and Kaduna rivers. They flow gently across the plains and form beautiful waterfalls as they tumble into deep gorges in parts of the region.

The Niger River serves as a major transportation route in Nigeria. The river flows southward through west-central Nigeria and cuts through grassland, tropical forests, and swampy plains. It empties into the Gulf of Guinea, an arm of the Atlantic Ocean.
The Jos Plateau lies near the center of Nigeria. It rises harpy from the surrounding plains. Parts of the region are more than 5,000 feet (1,500 meters) above sea level. Cattle graze on the plateau’s grasslands, and the area also has important tin mines.

The Niger-Benue River Valley forms an arc across central Nigeria, from east to west. The Niger River flows southeastward from Benin through west-central Nigeria. The Benue River cuts across east-central Nigeria. The two rivers meet near the center of the country and flow northward to the Niger Delta. Grasslands, palm forests, and swampy plains cover parts of the valley. Other areas are marked by rugged, rocky hills.

The Western Uplands, also known as the Plateau of Cross River, lie about 1,000 to 2,000 feet (300 to 610 meters) above sea level in west-central Nigeria. Dome-shaped granite hills dot the grassy plains of the uplands.

The Eastern Highlands stretch along the eastern border of Nigeria. They consist of plateaus and low, rocky mountains and hills. Much of the region is more than 4,000 feet (1,200 meters) above sea level. Dimlang Peak, the highest point in Nigeria, rises 6,699 feet (2,042 meters) above sea level in the Sheshi Mountains.

The Southwestern Plains consist of a heavily forested area that slopes gently northward from the Gulf of Guinea, an arm of the Atlantic Ocean. Swamps and lagoons cover much of the coastal region. Lagos, the largest city of Nigeria, occupies several islands in the Lagos Lagoon.

The Southeastern Lowlands resemble other parts of southern Nigeria, with swamps and forested plains covering much of the region. In the northwestern part of this region, however, steep-sided plateaus rise to about 1,000 feet (300 meters) above sea level.

The Niger Delta forms the southernmost region of Nigeria, along the Gulf of Guinea. It consists of deposits of clay, mud, and sand at the mouth of the Niger River. Lagoons and mangrove swamps cover much of the region. This area is also the site of Nigeria’s important petroleum deposits.

Climate. Most of Nigeria has a tropical climate, with warm temperatures throughout the year. The north is generally hotter and drier than the south. The average annual temperature in the north is about 85 °F (29 °C), but daily temperatures may rise above 100 °F (38 °C). The average annual temperature in the south is about 80 °F (27 °C).

Southern Nigeria receives far more rainfall than the northern part of the country. The coastal areas of Nigeria have an average annual rainfall of about 150 inches (381...
centimeters). Parts of the north receive only about 25 inches (64 centimeters) of rainfall annually. The rainy season lasts from April to October in most parts of Nigeria, though it usually extends for a longer time in the south.

**Economy**

Nigeria has a developing economy based on agriculture and mining. Agriculture employs about two-thirds of all Nigerian workers, but it accounts for only about one-fifth of the total value of Nigeria’s economic production. Since the late 1960’s, the development of the oil industry has made mining the fastest-growing part of the economy. In the early 1960’s, mining accounted for less than 2 percent of the value of economic production. Today, it accounts for about 70 percent of the value of production, and revenue from oil exports provides the government with its chief source of income.

Nigeria’s factories produce a wide variety of goods. However, manufacturing employs only about 10 percent of the country’s work force. Manufacturing also accounts for less than 10 percent of the value of Nigeria’s economic production.

The federal and state governments of Nigeria control communication, transportation, and electric power production. Most businesses and industries are privately owned, but the federal government shares in the ownership of some.

**Natural resources.** Nigeria has a variety of natural resources. More than half of Nigeria’s land is suitable for farming and grazing. However, only about 15 percent of the country’s total area is used for growing crops. Forests cover about one-third of Nigeria. Lakes, rivers, and streams provide an abundance of fish.

Petroleum ranks as Nigeria’s most valuable natural resource. Large oil fields lie in southwestern Nigeria and offshore in the Gulf of Guinea. The Jos Plateau of central Nigeria has important deposits of tin and columbite, a mineral that is used in the production of certain kinds of steel. Other important natural resources include coal, iron ore, lead, limestone, natural gas, and zinc.

**Agriculture.** Nigeria ranks among the world’s leading producers of cacao, palm oil and palm kernels, peanuts, and rubber. The country’s other important crops include beans, cassava, corn, cotton, millet, rice, sorghum, and yams. Farmers throughout Nigeria raise goats, poultry, and sheep. Cattle are raised primarily in the north. Nigerian fishing crews catch shrimp and a variety of other seafoods.

Farms in Nigeria average only about 2 ½ acres (1 hectare) in size. Most of the farmers use old-fashioned tools and methods. The government sponsors programs to distribute fertilizer, insecticides, and new varieties of seeds to farmers.

**Mining.** Nigeria ranks as one of the world’s leading exporters of petroleum. Foreign oil companies operate most of the petroleum wells, but they pay the Nigerian government more than half their profits. In 1971, the government of Nigeria established a national oil corporation to explore for and produce oil. In addition to petroleum, Nigeria produces coal, columbite, gold, iron ore, lead, limestone, natural gas, tin, and zinc.

**Manufacturing.** Leading industries in Nigeria produce cement, chemicals, clothing, fertilizers, food products, leather goods, lumber, metal products, and textiles.

The country also has motor vehicle assembly plants, petroleum refineries, steel mills, and factories that process rubber.

**Transportation and communication.** Railroads and paved roads link Nigeria’s major cities. But many of the country’s roads are unpaved and rutted. Less than 1 percent of all Nigerians own an automobile. Buses and taxis—often jammed with passengers—operate along the main roads. Nigeria’s chief ports are Lagos and Port Harcourt. Abuja, Kano, and Lagos have the country’s largest airports. Nigeria Airways provides domestic and international service.

More than 20 daily newspapers, representing a variety of political opinions, are published in Nigeria. The national and state governments operate radio and television systems that broadcast in more than a dozen languages. The country also has several private radio and television stations. Nigeria has an average of about 1 radio for every 6 people and 1 TV set for every 50 people.

**International trade.** Petroleum accounts for more than 90 percent of the total value of Nigeria’s exports. Nigeria belongs to the Organization of Petroleum Exporting Countries (OPEC), an association of countries whose economies depend heavily on oil exports. In addition to oil, Nigeria exports cacao beans, rubber, timber, and tin. Chief imports include cement, chemical products, food products, machinery, manufactured goods, and textiles. Nigeria’s most important trade partners are Brazil, France, Germany, Japan, the Netherlands, South Korea, the United Kingdom, and the United States.

**History**

People lived in what is now Nigeria thousands of years ago. In parts of Nigeria, archaeologists have found stone tools that are 40,000 years old. Human skeletons,
ock paintings, and other remains of prehistoric settle-
ments have also been found.
The Nok civilization flourished in what is now central Nigeria from about 500 B.C. to A.D. 200. The clay figures of animals and people produced by this civilization are among the oldest known examples of African sculpture.

**Early kingdoms.** The kingdom of Kanem developed about the A.D. 700's in what is now Chad. Beginning in the 1000's, Kanem adopted Islam as its religion and gradually expanded its territory. By the 1300's, Bornu, now known as Borno, in what is now northeastern Nigeria, had become the political center of the kingdom. The Kanem-Borno kingdom traded with countries in Africa, Asia, and Europe.

After about A.D. 1000, a number of Hausa states grew up in the region west of Bornu. Some of these states, such as Kano and Katsina, traded with other countries in North Africa and the Middle East. Kano, Kebbi, and some other Hausa states became part of the Songhai Empire, a west African state that flourished during the 1400's and 1500's. During the early 1800's, Usman dan Fodio (also called Uthman ibn Fudil), a Fulani who was a Muslim religious leader, declared war on the Hausa states. His forces gained control of almost all northern Nigeria except Bornu. He turned the area into a Muslim empire called the Sokoto Caliphate.

In the south, the Yoruba people had established an important cultural center at Ife as early as the mid-900's. Yoruba rulers from Ife later founded states in various parts of the surrounding territory. The most important of these was the kingdom of Oyo, which extended into what is now the country of Benin during the 1700's.
The kingdom of Benin flourished from the early 1400's to the 1800's. It developed between Lagos and the Niger Delta and grew into a prosperous trade center. The kingdom also became famous for its sculptures of brass, bronze, and ivory.

**The coming of the Europeans.** The Portuguese were the first Europeans to reach Nigeria. They established a trade center near Benin in the late 1400's and developed a trade in slaves with the African leaders. British, Dutch, and other European traders later competed for control of the trade. By the 1700's, the British were the leading slave traders on the Nigerian coast. In 1807, the British government outlawed the slave trade. The United Kingdom signed treaties with other European countries and with local African rulers in an attempt to end the trade. British ships sailed along the Nigerian coast and captured ships that carried slaves. The British then set the slaves free at Freetown in Sierra Leone. British missionaries converted many of the freed slaves to Christianity. Some of the freed slaves later returned to Nigeria and helped spread Christianity along the coastal areas and in the southwest.

**British rule.** After 1807, British traders began to deal in palm oil and other agricultural products of the Nigerian coastal region. They explored the Niger River and other waterways in search of valuable natural resources. In 1851, the United Kingdom seized the port of Lagos to increase its influence over the area. Lagos served as a base from which the British continued their war against the slave trade. Lagos became a British colony in 1861.

During the late 1800's, the United Kingdom established protectorates in parts of southern Nigeria. A British trading firm called the Royal Niger Company ruled most of northern Nigeria until 1900. That year, the British government made the region the Protectorate of Northern Nigeria. In 1906, all of southern Nigeria, including Lagos, became the Colony and Protectorate of Southern Nigeria. Nigerians in many areas, especially in the north, fought unsuccessfully against the establishment of British rule. In 1914, the United Kingdom joined the northern and southern regions into one unit—the Colony and Protectorate of Nigeria.

**Independence.** During the 1920's, Nigerians began to demand representation in the British colonial government. In the 1940's, their demands began to be met.

In 1946, the United Kingdom divided Nigeria into three regions—north, west, and east. Each region had an assembly composed of Nigerian and British members. The assemblies acted as advisory bodies to the central government in Lagos. A Constitution adopted in 1954 gave the assemblies increased powers and established Nigeria as a federation. Abubakar Tafawa Balewa, a northern leader, became the federation's first prime minister in 1957. On Oct. 1, 1960, the United Kingdom granted Nigeria independence. Balewa remained prime minister. Nnamdi Azikiwe, a political leader from the eastern part, became the first person to hold the ceremonial office of president of Nigeria.

In 1961, the United Nations (UN) organized a referendum in western Cameroon, a UN trust territory that bordered Nigeria on the east. As a result of the referendum, the northern part of the territory joined Nigeria, and the southern part joined Cameroon.

During the early 1960's, various ethnic groups competed for political power within Nigeria's three regions. In 1963, a Mid-Western Region was created out of the Western Region. Some people in the Northern and Eastern regions also demanded separate political units. At the same time, the different groups competed for control of the central government. The people of southeastern Nigeria, especially the Igbo, resented the power of the Hausa people of the north. The northerners controlled the central government because the north had more people than the other regions. Censuses conducted in 1962 and 1963 showed that the north had an even

### Important dates in Nigeria

**c. 500 B.C.-A.D. 200** The Nok civilization thrived in what is now central Nigeria.

**c. A.D. 1000-1400's** Various kingdoms, including Benin, Kanem-Borno, Ife, and the Hausa states, began to develop in different parts of Nigeria.

**Late 1400's** The Portuguese became the first Europeans to reach Nigeria.

**1851** The British seized control of Lagos.

**1914** The British formed the Colony and Protectorate of Nigeria.

**1960** Nigeria became independent.

**1966** In January, military leaders overthrew Nigeria's government. In July, a second revolt established a new military government in Nigeria.

**1967-1970** Nigeria's Eastern Region declared itself an independent republic called Biafra. Biafra and the rest of Nigeria fought each other in a civil war until Biafra surrendered in 1970.

**1979** Civilian rule was restored in Nigeria.

**1983** Military leaders took control of Nigeria's government.

**1999** Nigeria returned to civilian rule.
larger population than had been expected. Many southerners protested against the census figures. Charges of dishonesty in a 1964 federal election and a 1965 regional election led to violent riots and added to the turmoil.

Civil war. In January 1966, a group of Army officers, mainly Igbo, overthrew the central and regional governments. They killed Prime Minister Balewa and the prime ministers of the Northern and Western regions. General Johnson Aguiyi-Ironsi, commander of the Army and an Igbo, took control of the government. In May, he abolished the federal system of government. He set up a strong central government and appointed many Igbo as advisers. Many northerners feared that these actions would give the Igbo control over the nation. Riots broke out in the north, and thousands of Igbo were killed.

In July 1966, a group of northern Army officers revolted against the government and killed Aguiyi-Ironsi. Yakubu Gowon, the Army chief of staff, became head of a new military government. But Colonel Odumegwu Ojukwu, the military governor of the Eastern Region, refused to accept Gowon as head of state.

In 1967, Gowon replaced the country’s 4 political regions with 12 states to give some of the smaller ethnic groups more political power. Ojukwu refused to accept the division of the Eastern Region into 3 states. On May 30, 1967, he declared the Eastern Region an independent republic called Biafra. Civil war between Biafra and the rest of Nigeria broke out in June 1967. Biafra surrendered in January 1970. The civil war caused widespread death and destruction in southeastern Nigeria. Beginning in 1970, the government sponsored reconstruction and relief programs to overcome the effects of the war. Many Igbo, including some who had fought with rebel forces, were given government positions.

Oil wealth. During the early 1970’s, Nigeria’s growing oil industry provided the country with an important source of wealth. Oil profits enabled the government to plan development programs to improve the standard of living of all Nigerians. Major goals included the establishment of manufacturing industries, new schools, and improved transportation facilities. But political problems continued in Nigeria. In 1975, military leaders overthrew General Gowon. General Murtala Ramat Muhammad became head of state and commander in chief of Nigeria’s armed forces. In 1976, a group of military officers tried to overthrow the government. They failed, but killed General Muhammad. Lieutenant General Olusegun Obasanjo succeeded him. Also in 1976, Nigeria increased its number of states from 12 to 19. Military rule ended in 1979. The people elected a new civilian government to replace the military government. Shehu Shagari became president. He was reelected in 1983.

The wealth that Nigeria gained from its oil exports in the 1970′s attracted many people from neighboring lands. These people came to Nigeria to find work. But in the early 1980′s, declining oil prices began to hurt Nigeria’s economy. In 1983 and again in 1985, the government ordered foreigners who were living in Nigeria illegally to leave the country. Many people from Ghana and other countries were required to leave Nigeria.

In 1980, Nigeria’s government began building a new city, Abuja, near the country’s center to replace Lagos as the capital. Abuja became the official capital in 1991.

Recent developments. In December 1983, the military overthrew the civilian government. Major General Muhammadu Buhari became head of a new military government. In 1985, he was overthrown by other military leaders. Major General Ibrahim Badamosi Babangida became government head. He announced that Nigeria would return to civilian rule. The government formed two political parties in 1989. Elections for a new National Assembly occurred in 1992. Elections for a civilian president were held in June 1993. But Babangida canceled the presidential election results, charging that the voting had been dishonest. Many Nigerians rioted in protest.

In November 1993, General Sani Abacha overthrew the Interim National Government that Babangida had set up in the summer. That government was headed by a civilian, Ernest Shonekan. Abacha made himself head of state and commander in chief of the armed forces. He dissolved the National Assembly, outlawed political parties, and dismissed all elected local government officials. In 1995, he ended the ban on political parties. In 1996, Nigeria increased the number of its states to 36. Abacha died in June 1998. General Abdulsalami Abubakar became president. In 1999, Nigeria held elections for the National Assembly and presidency and adopted a new constitution. Olusegun Obasanjo, who as a military ruler had ceded power to a democratically elected government in 1979, was elected president as a civilian.

Since 1999, ethnic, religious, and political tensions in Nigeria have sparked several outbreaks of violence in which thousands of people have died. Many conflicts have been over access to land or other scarce resources. The adoption of Sharia (Islamic law) in several northern Nigerian states has led to clashes between Muslims and Christians. Light. See Day.

Night vision systems are electronic devices used by military forces to detect and track targets at night. Police officers and hunters also use these devices.

Night vision goggles help a soldier see at night. The goggles magnify starlight and moonlight reflected by objects to produce an image of the objects.

The most advanced night vision system is the Forward-Looking Infrared (FLIR) system, developed in the late 1960's. The FLIR uses a technique called thermal imaging, which detects and records minute temperature variations. The FLIR converts the temperature readings into electrical signals that generate a clear, black-and-white video image in which hot areas appear bright and cold areas appear dull. FLIR systems cannot be easily detected. When combined with powerful lenses, these systems have an extended range, and they perform relatively well even in bad weather or smoky conditions.

The first night vision systems used special searchlights that sent out infrared rays to illuminate an area. The infrared rays were invisible except when viewed through a special filter. Infrared systems were easily detected. They had a limited range, and they did not work well in bad weather or smoky conditions.

In the early 1960's, image intensifying systems (sometimes called starlight scopes) were introduced. These systems have special tubes that magnify the starlight and moonlight reflected by objects and then focus the light on a viewing screen to produce an image.

Kenneth S. Brower

Nighthawk, also called bullbat and mosquito hawk, is a bird that looks much like the whippoorwill, to which it is related. It is not a hawk. The nighthawk measures about 10 inches (25 centimeters) long. It has mixed brown, black, and white feathers, and a white throat patch. It has a white bar on each wing. Soon after sunset, the nighthawk flies to look for insects. It breeds throughout most of the United States and Canada. In winter, it is found in South America. The female lays two speckled eggs on the ground or on gravel rooftops.

Bertin W. Anderson

Scientific classification. The nighthawk belongs to the nightjar family, Caprimulgidae. The eastern nighthawk is Chordeiles minor.

Nightingale is a small, dull-colored bird famed for its beautiful, sad song. The bird belongs to the thrush family. It lives in central and western Europe for most of the year, but it spends winters in Africa.

The nightingale grows about 6 to 7 inches (15 to 18 centimeters) long. The upper parts of its body are russet-brown in color, and the underparts are predominantly grayish-white. The bird has a rounded tail. Its relatively long legs are well suited to traveling on land.

Nightingales usually live in dense woodland undergrowth and along streams in swampy thickets or hedges. They normally feed on insects and worms.

The nighthawk often flies in urban areas during the evening, hunting for insects that are attracted by the city lights.

The nightingale is a small thrush known for its melancholy song. Nightingales nest in thickets or hedges near the ground.
When searching for food, the birds hop rapidly along the ground for a few moments and then stand motionless to listen for prey. Their songs are heard most often during spring or summer, usually in the early morning or late evening. Sometimes the songs last well into the night. The songs vary in their notes and may include imitations of other bird calls.

Nightingales usually have one brood of young each year. They build a nest near the ground in dense thickets or hedges. The female lays four to six olive-brown eggs. Both parents care for the young. 

Scientific classification. The nightingale belongs to the thrush subfamily, Turdinae, in the family Muscicapidae. The scientific name of the nightingale is Luscinia megarhynchos.

Nightingale, Florence (1820-1910), was the founder of the nursing profession as we know it today. British soldiers who were wounded in the Crimean War called her “The Lady with the Lamp” when she walked the halls of their hospital at night. The light that Nightingale carried has come to mean care for the sick, concern for the welfare of the ordinary soldier, and freedom for women to choose their own work.

Early years. Florence Nightingale was named for Florence, Italy, where she was born on May 12, 1820, while her wealthy British parents were living abroad. Her childhood was spent on the family estates in England with her mother, father, and sister Parthenope. The girls' mother, Frances, taught her daughters the social graces and how to run a large household. Their father, William, tutored them in languages, history, and philosophy.

At the age of 16, Florence thought she heard the voice of God telling her she had a special mission in life. She suspected this mission had something to do with helping other people. Florence had always enjoyed caring for the babies of her parents' visitors and for sick farmers on her father's estates.

Nightingale followed her own sense of purpose by turning down suitors, declining many parties, and spending much time studying health and reforms for the poor. Her mother could not accept such behavior, which was not considered proper for a wealthy young woman.

Her family's opposition initially prevented Nightingale from working in a hospital. She took a step toward independence when she entered the Institution of Deaconesses, a Protestant school for training nurses, in Kaiserswerth, a town near Düsseldorf, Germany. She later studied in Paris. At 33, she became superintendent of a women's hospital in London.

Service in Crimea. Britain and France went to war with Russia in the Crimea, now part of Ukraine, in 1854. The British people were angry when they heard that their troops had been sent to battle without enough supplies, to die under terrible conditions. The secretary of war asked Florence Nightingale to take charge of nursing. She sailed for the Crimea with 38 nurses.

Nightingale and the other nurses stepped ashore in the mud of Scutari, across from Constantinople (now Istanbul), in late 1854. They faced a job that seemed impossible. Wounded troops had just arrived from the Battle of Balaklava, where the charge of the "Light Brigade" had taken place. About 250 of the British cavalrymen had been killed or wounded in the battle in 20 minutes.

The hospital was an old Turkish barracks, rat-infested, dirty, and poorly furnished. Many of the wounded lay on floors, bleeding and neglected. There were not enough cots, mattresses, or bandages, and no workstations, soap, or towels. Nightingale found a few men well enough to clean the place, and she put them to work at once. She set up a nursing schedule for patient care and work. At night, her lamp burned as she walked the miles of corridors or wrote countless reports and letters demanding supplies from British military officials. When the hospital was running smoothly, she started classes to teach convalescent soldiers to read and write.

At first, doctors and officials resented the "dictatorship of a woman." But they eventually came to respect her tireless efforts and professional skills.

While on a visit to the front lines, Nightingale became seriously ill and nearly died. By that time, she had become famous, and even Queen Victoria kept an anxious watch on her recovery.

---

*Grainger Collection*  
Florence Nightingale, above, introduced sanitary methods of nursing in wartime. In a hospital in Scutari, she attended to the needs of British soldiers wounded in the Crimean War, left.
After she returned to the Scutari hospital, Nightingale was urged to go to England to get her strength back. She replied firmly that she was "ready to stand out the war with any man." Nightingale's success at Scutari became so widely recognized that she was given charge of all the British Army hospitals in the Crimea. By the end of the war, Nightingale had saved many lives and had brought about worldwide reforms in hospital administration and in nursing.

Return to England. England greeted her arrival in 1856 with big celebrations. Instead of attending them, Nightingale went quietly home to her family, and then moved to London. The strain of overwork and her Crimean illness had injured her health. Nightingale became a semi-invalid and seldom left her rooms. Instead, the world came to her.

Ministers, heads of government, authors, reformers, and politicians came to ask her advice. Nightingale's report of over 1,000 pages to the British War Department brought about the formation of the Royal Commission on the Health of the Army in 1857. By correspondence and constant reading, she made studies of health conditions in India. Another Royal Commission was appointed in 1859, resulting in the establishment of a Sanitary Department in India in 1868.

In 1860, Nightingale used donations of about $222,000 to found the Nightingale Training School for Nurses at St. Thomas's Hospital in London. She became a world authority on scientific care of the sick. The United States asked Nightingale's advice for setting up military hospitals during the American Civil War (1861-1865). Nightingale received many honors and was the first woman to be given the British Order of Merit.

Nightjar. See Goatsucker.
Nightmare is a frightening dream or dreamlike experience that awakens a sleeper. After awakening from most nightmares, the sleeper can recall the dream that caused the fright. Another kind of frightening sleep event, called a night terror, occurs without a true dream. The sleeper awakes terrified early in the night, often with a feeling of pressure on the chest. Night terrors occur during the first hours of sleep. True nightmares occur later, during dreaming sleep (see Sleep What happens during sleep).

Nightmares may occur in times of severe tension. They have been experienced by many soldiers in combat and by persons withdrawing from alcohol or certain other drugs. All children between the ages of 2 and 6 probably have some nightmares. Some nightmares seem entirely real to a youngster after awakening. Most adults do not have nightmares. Frequent nightmares among older children or adults may indicate a physical or emotional problem. Ernest Hartmann

Nihilism, NY uh liz uhm, is the name used for a variety of extreme, negative philosophical and political views. The term nihilism comes from a Latin word meaning nothing. The most radical nihilist would deny that anything exists. A slightly less radical view, usually called skepticism, denies that anything can be known.

Nihilism is most commonly understood as the view that no absolute values exist. The Russian author Fyodor Dostoevsky challenged this view in his novel The Brothers Karamazov (1879-1880). He wrote that if no God exists, then everything is permitted. He argued that belief in God is necessary for believing in any absolute values.

The term nihilist first came into popular use during the mid-1800s in Russia. It applied to radical opponents

of the czar, some of whom committed terrorist acts against the government. Used more broadly, nihilism referred to any extreme challenge to authority. Ivan Turgenev portrayed a nihilist in his novel Fathers and Sons (1862). This character believes in reason and a scientific conception of the world, but he rejects traditional religious beliefs and moral values.

Stephen Nathanson

**Nijinsky**, nih ZHIHN skee or nih JIHN skee, Vaslav, vahts LAHF (1890-1950), was the most famous male dancer of his time. He was short, with thick thighs and sloping shoulders. Yet he acted out his roles so completely that his appearance seemed to change from one role to another.

Nijinsky had such amazing body control that his dancing looked spontaneous and effortless. One legend tells of a dramatic leap he made through an open window as his exit in Le Spectre de la Rose. Nijinsky rose slowly, soared across the window ledge, appeared to stop in midair, and was still at the height of his jump as he disappeared.

Nijinsky was born in Kiev, Ukraine (then a part of the Russian Empire). He first studied dancing at the St. Petersburg Imperial School of Ballet in 1898. He traveled with Sergei Diaghilev's ballet company to Paris in 1909 and had great international success until 1913. He married a ballet student with the company in 1913, and Di-

![Vaslav Nijinsky created the choreography and also danced the part of the faun in The Afternoon of a Faun in 1912.](https://www.bettmann.com/rights-available/image/26302678)

aghilev dismissed him. Nijinsky rejoined the company in the United States in 1916, dancing as brilliantly as ever. But in 1917, mental illness ended his career.

**Nike, Temple of.** See Acropolis.

**Nike of Samothrace.** See Winged Victory.

**Nikolaïs, NEE koh ly, Alvin** (1912-1993), was an American choreographer (creator of dances). His works are clever combinations of human movement, costumes, lighting, props, and scenery. Nikolaïs designed such visual elements of a performance and also composed the music.

Nikolaïs's dances do not tell a story. Instead, they consist of continually changing and unusual visual images. For example, in *Masks, Props, and Mobiles* (1953), the dancers are enveloped by elastic bags and thus become strange, humanlike shapes.

Nikolaïs was born in Southington, Connecticut. In the 1940's, he studied with the German dancer Hanya Holm. From 1948 to 1970, he headed the dance department of the Henry Street Playhouse in New York City. About 1950, he formed his own dance company.

In 1989, Nikolaïs and dancer Murray Louis combined their dance companies to form Nikolaïs-Louis Dance. Nikolaïs's major works include Kaleidoscope (1956), Totem (1960), Imago (1963), Triad (1976), and Crucible (1985).

Katy Matheson

**Nile River** is the longest river in the world. It flows for 4,160 miles (6,655 kilometers) through northeast Africa. The Nile rises near the equator and flows into the Mediterranean Sea. The Nile irrigates about 6 million acres (2.4 million hectares) of land in Egypt and about 2 million acres (1.1 million hectares) in Sudan.

The Nile Valley and the Nile Delta rank among the world's most fertile farming areas. Until 1968, water from the Nile deposited fertile silt (particles of soil) in the valley and on the delta, where the Nile flows into the Mediterranean. The Nile also flooded certain areas every summer.

In 1968, the Aswan High Dam at Aswan, Egypt, began operating. This dam ended the annual floods and trapped the Nile's silt in Lake Nasser, behind the dam. Without the deposits of silt, Egyptian farmers had to use more artificial fertilizers on their soil. But the high dam and other dams built during the 1900's generate electric power and provide a steady flow of water for irrigation.

**The course of the Nile.** The Nile flows generally northward throughout its course. Its southernmost source is the Ruvironza River in Burundi. Lake Victoria ranks as the Nile's largest source. The Nile flows through the Sudd, a vast swamp in southern Sudan, where high temperatures cause about half of the water to evaporate.

The Nile is called the White Nile between the Sudd and Khartoum, Sudan. At Khartoum, the Blue Nile from Ethiopia joins the White Nile. North of Khartoum, the waterway is called simply the Nile. The Atbara River, which is another chief source of the Nile, drains into it in Sudan, about 175 miles (282 kilometers) north of Khartoum.

About 70 percent of the Nile's water comes from the Blue Nile. The flow of water in the Blue Nile and the At-
The Nile River

The Nile River irrigates large strips of farmland. The Egyptian farm village shown above lies north of the Aswan High Dam.

The Blue Nile, one of the two main branches of the Nile, has carved out a deep valley in Ethiopia, above.

Kabalega Falls, above, is on the Victoria Nile in western Uganda, about 20 miles (32 kilometers) east of Lake Albert.

para varies greatly. Flooding by these rivers caused the annual floods of the Nile in Egypt.

North of Cairo, Egypt, the Nile divides into separate channels in the Nile Delta. The delta has some swampy and salty lakes, as well as highly fertile soil.

The Nile Valley and Nile Delta make up a total of about 3 percent of Egypt’s area. Almost all Egyptian arms lie in this densely populated region. Water from the Nile enables farmers in the valley and delta to raise various crops the year around. The chief winter crops, in order of area planted, include clover, wheat, and beans and other vegetables. The main summer crops are cotton, corn, rice, and millet. Cotton is Egypt’s most important crop financially.

Nilsson, Birgit (1918–), is a celebrated Swedish dramatic soprano. She became noted for the power and clarity of her voice. Critics generally regard Nilsson as one of the finest singers of heroic roles in the operas of Richard Wagner. Her performances as the Wagnerian heroines Isolde and Brünnhilde set the standard for her time. Nilsson also achieved fame in the roles of Aida, Lady Macbeth, Salome, and Tosca. However, a large number of critics rate Nilsson’s performance in the title role of Giacomo Puccini’s Turandot as her outstanding achievement.

Nilsson was born in Vastras Karup, near Malmö. She made her opera debut in 1946 as Agathe in Carl Maria von Weber’s Der Freischütz at the Royal Opera of Stockholm. She first appeared at the Metropolitan Opera in New York City in 1959 as Isolde. Nilsson’s recordings are considered masterpieces of dramatic soprano singing.

Nimitz, NHM ihtas, Chester William (1885-1966), served as commander in chief of the United States Pacific Fleet during World War II (1939-1945). He took command on Dec. 31, 1941, about three weeks after the fleet had been almost completely disabled in the Japanese attack on Pearl Harbor.

Admiral Nimitz painstakingly rebuilt U.S. strength in the Pacific. As commander of the Pacific Fleet and the Pacific Ocean Areas, he directed the Navy and the Marine Corps forces. His calm assurance of final victory helped restore the faith of the Navy in its own power and ability.

In the early months of the war, Admiral Nimitz refused to attack before U.S. forces were fully ready, in spite of angry questions from Congress and newspapers. He waited until he had enough ships, supplies, and troops to assure victory. Nimitz developed much of the strategy of island hopping (seizing only key islands from which attacks on other key islands could be launched). This strategy saved lives and time. Nimitz led the fleet through many victories until it drove the Japanese back to Japan. He was promoted to fleet admiral in 1944. Nimitz signed for the United States at the Japanese surrender ceremonies in Tokyo Bay in 1945.

After the war, Nimitz became chief of naval operations. He left active duty in 1947, and then became special assistant to the secretary of the Navy. Nimitz headed the United Nations commission that mediated the dispute over Kashmir in 1949. Nimitz was born in Fredericksburg, Texas, and graduated from the U.S. Naval Academy in 1905.

Ning-po. See Ningbo.

Ningbo, ning bwaH (pop. 3,350,851), also spelled Nings, is an industrial center and port in the Chinese province of Zhejiang. For location, see China (political map). In 1842, Ningbo became one of five Chinese "treaty ports" in which Britain won special trading rights (see China | Clash with the Western powers). The city produces industrial equipment. Its factories use iron from nearby mines.

Parris H. Chang

Niobe, NY oh bee, was a queen in Greek mythology who was famous for eternally mourning her dead children. Niobe was the daughter of King Tantalus and Queen Dione, and married Amphion, king of Thebes. She boasted that because of her six (or seven) fine sons and six (or seven) beautiful daughters, she deserved worship more than the goddess Leto, who had only two children, Apollo and Artemis. In anger, Leto ordered Apollo and Artemis to kill Niobe's children with their arrows. As Niobe wept unceasingly for her children, the gods in pity changed her into a rock that spouted water like tears. According to tradition, this rock with a waterfall below stands on Mount Sipylus in what is now Turkey.

Jon D. Mikalson

Niobium, my OH bee uhm, also called columbium, is a soft, silver-white or gray metallic element. In nature, it occurs chiefly combined with tantalum, another rare metal. Manufacturers alloy much niobium with nickel and steel to make strong structural materials that are resistant to high temperatures. Niobium is also used in the cores of certain nuclear reactors because it allows neutrons to penetrate easily and can withstand high-temperature reactor coolants. At extremely low temperatures, niobium becomes a superconductor, and so it is used in making superconducting magnets (see Superconductivity).

Niobium has the chemical symbol Nb. Its atomic number is 41, and its atomic weight is 92.90638. It melts at 2468 ± 10 °C and boils at 4742 °C. Niobium has a density of 8.57 grams per cubic centimeter at 20 °C (see Densities). Charles Hatchett, a British chemist, discovered niobium in 1801.

Nirvana, nihv VAH nuh, according to Buddhist belief, is perfect peace and blessedness. The attainment of nirvana enables a person to escape from a painful, continuous cycle of death and rebirth. This cycle is caused by an individual's worldly desires, such as a craving for fame, immortality, and wealth. People attain nirvana when such desires are completely eliminated. When they die, their cycle of death and rebirth ends.

Buddha, the founder of Buddhism, preached that nirvana can be attained by following a Middle Way between self-indulgence and self-denial, and by practicing the Noble Eightfold Path. The Noble Eightfold Path con-
sists of eight aspects of correct living, including proper behavior, proper meditation, and proper insight into truth. Frank E. Reynolds

See also Buddhism (The dharma).

Nitrate is any kind of compound that contains the inorganic nitrate ion \( \text{NO}_3^- \). Nitric acid (\( \text{HNO}_3 \)) is a nitrate. Most metals form nitrate salts when combined with nitric acid. In nature, there are relatively few nitrate minerals. Two important nitrates, potassium nitrate (\( \text{KNO}_3 \)) and ammonium nitrate (\( \text{NH}_4\text{NO}_3 \)), are used as fertilizers to replenish nitrogen in the soil. Bacteria in the soil form nitrates from organic compounds containing nitrogen. Plants use these nitrates to make proteins. Nitrates can also form in the atmosphere. There, nitrogen oxide oxide may combine with water to produce nitric acid, a part of the pollutant acid rain. Nitrates are also used in explosives, fireworks, heart medicine, and photographic films. People take in nitrates daily, primarily from vegetables. But consuming large amounts of nitrates can help produce toxic substances in the body. See also Nitric acid; Nitrogen cycle.

Emily Jane Rose

Nitrate of silver. See Silver nitrate.

Nitric acid is a strong inorganic acid that has many industrial uses. Its principal use is for the production of fertilizers and explosives. Large quantities of nitric acid are produced during thunderstorms and fall to the earth in rain. The rain falls as a very weak solution of nitric acid. The production of nitric acid during thunderstorms allows nitrogen from the air to become part of the soil in a form that plants can use (see Nitrogen cycle). Nitric acid was one of the first acids known. Many alchemists of the Middle Ages used it in their experiments.

Nitric acid is such a powerful oxidizing agent that it dissolves many metals. But it does not attack gold and platinum. A drop of nitric acid on a piece of jewelry tells whether it is made of genuine gold or platinum. These two metals can be dissolved by \( \text{HNO}_3 \), a mixture of nitric acid and hydrochloric acid (see Aqua regia).

Nitric acid is used to manufacture ammonium nitrate, \( \text{NH}_4\text{NO}_3 \), an ingredient of many fertilizers, and to make explosives, flares, and rocket propellants. The chemical industry uses nitric acid to prepare nylon and many organic compounds that are used as dyes and drugs. Nitric acid reacts with toluene in the presence of sulfuric acid to form trinitrotoluene, better known as TNT.

Commercially, most nitric acid is produced by oxidizing ammonia using a platinum catalyst. Ammonia and air are passed through heated platinum gauze. The gases react to form water, nitric oxide (\( \text{NO} \)), and nitrogen dioxide (\( \text{NO}_2 \)). Upon cooling, this gaseous mixture forms nitric acid. This method is called the Ostwald process, after Wilhelm Ostwald, the German chemist who developed it. Nitric acid is also produced by heating saltpeter with sulfuric acid. In this process, nitric acid is recovered by distillation.

Nitric acid is a colorless liquid with a suffocating odor. It develops a yellow color if kept in bottles that are not tightly stoppered. This is due to nitric dioxide gas that results from decomposition of the acid. Nitric acid stains the skin yellow and can cause burns. Its chemical formula is \( \text{HNO}_3 \). The metal salts of nitric acid, called nitrates, are soluble in water. Marianna A. Busch

Nitrite is a compound of the nitrite anion \( \text{NO}_2^- \) and some other element. An anion is a negatively charged ion. Inorganic nitrates are stable and soluble in water. Most organic nitrates are made from alcohols. They are unstable when in the presence of acid, but they are preserved satisfactorily in neutral or mildly alkaline solutions. Nitrates are used in medicine for heart ailments. Sodium nitrite is important in making dyes. It is also used to cure meats, such as bacon, to prevent botulism and to give the meat a pinkish color. Under certain conditions, sodium nitrite may combine with chemicals called amines to form nitrosamines, which can cause cancer. The U.S. Department of Agriculture limits the amount of sodium nitrite allowed in cured meats. Nitrates are also used in photography and in the manufacture of organic materials. Patrice C. Bélanger

Nitrogen is a nonmetallic chemical element. It occurs in nature as a colorless, odorless, and tasteless gas. This gas makes up about 78 percent of the earth's atmosphere by volume. Daniel Rutherford, a Scottish physician, discovered nitrogen in 1772.

The chemical symbol for nitrogen is \( \text{N} \). Nitrogen's atomic number is 7, and its atomic weight is 14.0067. Nitrogen gas consists of two nitrogen atoms bonded together to form a molecule with the chemical formula \( \text{N}_2 \). The gas may be condensed to a liquid that boils at \(-195.8^\circ\text{C}\) and freezes at \(-209.9^\circ\text{C}\). Nitrogen gas does not combine easily with other elements. But nitrogen atoms are part of many chemical compounds.

Nitrogen and life

All organisms must have nitrogen to live. Nitrogen is part of all amino acids, the building blocks of proteins. Plants make all the amino acids they need. Animals produce only some of these compounds and must get the rest by eating other animals and plants.

Nitrogen is constantly being removed from the air and returned to it in a series of chemical reactions known as the nitrogen cycle. In the first part of this process, called nitrogen fixation, nitrogen gas is converted to nitrogen compounds that plants can use. Nitrogen in the air reacts with water to form nitric acid, which is deposited in the soil by rain. In addition, certain bacteria and yeasts change nitrogen from the air into compounds plants can use. Bacteria in swellings on the roots of legumes, such as peas and beans, can also do this.

In the next stage of the nitrogen cycle, plants use nitrogen compounds in the soil to make protein. Fertilizers increase the usable nitrogen in the soil. Plant proteins are then eaten by animals. In the final stage, the decay of animal wastes and of dead plants and animals returns nitrogen compounds to the soil and nitrogen gas to the atmosphere. See Nitrogen cycle.

Uses of nitrogen

Manufacturers obtain pure nitrogen by making liquid air. They then separate the nitrogen from the oxygen and other gases in air by the process of distillation (see Liquid air). During the process of distillation, the nitrogen is collected and stored under pressure in specially designed metal containers. Small amounts of nitrogen can be prepared by gently heating a water solution of ammonium nitrate.

Pure nitrogen gas is used as a "blanket" by certain industries to keep oxygen away from specific areas. For example, the food industry uses nitrogen to prevent oxi-
Nitrogen from reaching such foods as fresh fruits and spoil- ing them. The food industry also uses liquid nitrogen to quick-freeze food and to refrigerate food during transport. Scientists use liquid nitrogen to produce the low temperatures needed in some experiments.

Production of nitrogen compounds. The principal use of nitrogen is in the production of ammonia (NH₃), a gas that consists of nitrogen and hydrogen. Manufacturers produce ammonia chiefly by the Haber process. In this process, nitrogen and hydrogen are combined at high temperatures and pressures (see Haber process). Ammonia is used as a fertilizer, as a refrigerant, and in the production of nitric acid and other chemicals.

Household ammonia, which is a cleaning agent, consists of a dilute solution of ammonia gas in water. See Ammonia.

Nitric acid is a second major nitrogen compound pro- duced by industry. It is made from ammonia in a series of reactions called the Ostwald process. Nitric acid is used mainly to make fertilizer (see Nitric acid). Nitrogen compounds are also important in drugs, dyes, explosives, poisons, and synthetic fibers.

Nitrogen in agriculture. Almost all fertilizers con- tain nitrogen, which is necessary for the healthy growth of plants. Farmers may inject ammonia gas directly into the soil. Liquefied ammonia and such compounds as ammonium sulfate and ammonium nitrate are also used as nitrogen fertilizers. Other sources of nitrogen include inorganic compounds, manure, and guano, the waste material of sea birds. See Fertilizer.

Farmers can also supply nitrogen to their fields by rotating crops. In crop rotation, a farmer plants a field one year with corn, wheat, or some other crop that removes nitrogen from the soil. The next year, the farmer plants the field with legumes that restore nitrogen to the soil.

Nitrogen and pollution

People influence the nitrogen cycle. The use of nitrogen fertilizers adds nitrogen to the soil. Rain water carries unused fertilizer and other nitrogen compounds into streams and lakes, where the compounds cause water plants and algae to multiply. As the plants and algae die and decay, they use up oxygen, endangering animal life in the body of water.

Nitrogen oxides pollute the air. Pollutants are released by burning fossil fuels, such as coal and gasoline. Sunlight causes nitrogen oxides in the lower atmos- phere to react with oxygen to form ozone, an irritating substance in smog. Nitrogen oxides can also return to earth as nitric acid, a major ingredient of acid rain.

Jet engines produce nitrogen oxides in the upper atmo- sphere, where the compound may harm the environment in a different way. Nitrogen oxides can promote the decomposition of ozone in the upper atmosphere. Here, ozone benefits animals and plants by shielding them from harmful ultraviolet light. Emily Jane Rose

Nitrogen cycle is the circulation of nitrogen among the atmosphere, the soil and water, and the plants and animals of the earth. All living things require nitrogen, but most organisms cannot use the nitrogen gas (N₂) that makes up about 78 percent of the atmosphere. They need nitrogen that has combined with certain other ele- ments to form organic compounds. But the supply of this fixed nitrogen is limited, so complex methods of re- cycling nitrogen have developed in nature.

One part of the nitrogen cycle involves circulation of nitrogen between the soil and living things. After plants and animals die, they undergo decomposition by certain bacteria and fungi. These microorganisms produce ammonia (NH₃) from nitrogen compounds in dead organic matter and in body wastes excreted by animals. Plants absorb some of the ammonia and use it to make pro- teins and other substances essential to life. The rest of the ammonia is changed into nitrates (NO₃⁻) by nitrifying bacteria. First, nitrifying bacteria called nitrite bacteria convert ammonia into nitrates (NO₂⁻ compounds). Then nitrate bacteria change nitrates into nitrites. Plants absorb most of the nitrates and use them in the same way as ammonia. Animals get nitrogen by eating plants or by feeding on animals that eat plants.

In another part of the cycle, a process called nitrogen fixation constantly puts additional nitrogen into biological circulation. In this process, nitrogen-fixing bacteria in the soil or water, or living within plants such as legumes, convert nitrogen from the atmosphere into nitrogen-containing organic substances.

While nitrogen fixation converts nitrogen from the atmosphere into organic compounds, a series of pro- cesses called denitrification returns an approximately equal amount of nitrogen to the atmosphere. Denitrifying bacteria convert nitrates and nitrites in soil into nitrogen gas or into gaseous compounds such as nitrous oxide (N₂O) or nitric oxide (NO). However, fixed nitrogen may circulate many times between organisms and the soil before denitrification returns it to the atmosphere.

Some human activities influence the nitrogen cycle. Industry fixes vast quantities of nitrogen to produce fer- tilizer, much of which is washed off farmland and into waterways, polluting the water. The combustion of cer- tain fuels produces nitrogen compounds that pollute the air. These compounds may also play a part in the warming of the earth's climate (see Greenhouse effect).

William A. Reiners

See also Nitrogen; Legume; Nitrate; Nitrite.

Nitroglycerin, ntr glik,s, is also called nitroglycerol, is a powerful explosive. Its chemical for- mula is C₃H₅(ONO₂)₃. It is the principal explosive ingredi- ent in dynamite. Nitroglycerin also is used by doctors as a heart medication.

As an explosive. Nitroglycerin is a heavy, clear or straw-colored liquid with a sweet, burning taste. The liq- uid freezes at slightly below room temperature to form needlelike crystals that explode when heated or broken. An explosion of nitroglycerin is about three times as powerful as that of an equal amount of gunpowder.

Chemists once made nitroglycerin by slowly adding glycerol, also known as glycerin, to concentrated nitric and sulfuric acids. After the mixture was stirred, the nitro- glycerin formed a layer on top of the two acids. This layer was drawn off and washed, first with water, and then with a solution of sodium carbonate. Today, chemists make nitroglycerin in smaller, safer batches in a type of tank called a Biazzi nitratort.

Aesculapian Sobreno, an Italian chemist, discovered
Nitrous oxide (Coronal artery disease).

Nitrous oxide, NY truhs AHK syd, is a colorless, odorless gas that physicians and dentists use to make patients insensitive to pain. Such drugs are called anesthetics. Nitrous oxide is commonly called laughing gas because people sometimes become excited and silly after they inhale it. Nitrous oxide causes unconsciousness if enough of it is inhaled.

Nitrous oxide is pleasant to inhale and it takes effect quickly. It also wears off rapidly and is nonflammable. Doctors always give oxygen with nitrous oxide because the body cannot use the oxygen in nitrous oxide molecules.

Nitrous oxide is a weak anesthetic, and it must be used at high concentrations to be effective. However, lower concentrations can relieve pain without producing true anesthesia and loss of consciousness. Such subanesthetic doses are frequently administered to women during childbirth and to patients undergoing dental treatment. However, the greatest use of nitrous oxide is as a supplement to more powerful anesthetics during major surgery.

Nitrous oxide was first prepared in 1772 by Joseph Priestley, a British chemist. In 1844, Horace Wells, a Hartford, Connecticut, dentist, was the first to actually use nitrous oxide. He inhaled the gas himself before having a tooth extracted, and the tooth was pulled painlessly. Nitrous oxide anesthesia became widely used in dentistry during the 1860's.

Nitrous oxide is also called nitrogen monoxide or dinitrogen monoxide. Its chemical formula is N₂O. It is used in industry as a propellant in aerosol products and as a "tracer gas" to locate leaks in vacuum and pressure lines.

Edwin S. Munson

See also Aerosol; Priestley, Joseph.
Nixon, Richard Milhous (1913-1994), was the only president of the United States ever to resign from office. He left the presidency on Aug. 9, 1974, while facing certain impeachment for his involvement in the Watergate scandal. This scandal included a break-in at the Democratic national headquarters and other illegal activities by employees of Nixon's 1972 reelection committee and members of his executive staff. Nixon's attempts to cover up these crimes became a major part of the scandal.

Nixon was succeeded as president by Vice President Gerald R. Ford. One month after Nixon resigned, Ford pardoned him for all federal crimes he may have committed during his presidency.

Although Nixon left office in disgrace, he won respect for his conduct of foreign policy. As president, he ended U.S. military participation in the Vietnam War in 1973 and eased the tension that had existed for years between the United States and both China and the Soviet Union. He became the first president to visit China while in office. He also visited the Soviet Union. He won congressional approval of U.S.-Soviet trade agreements and agreements to limit the production of nuclear weapons.

At home, Nixon was challenged by sharply rising prices. He placed government controls on wages and prices to halt inflation, but the controls had little effect. Nixon ended the military draft and created an all-volunteer system for the U.S. armed services. He signed into law a wide variety of economic, social, and environmental legislation that made him seem almost a liberal.

When Nixon was elected president in 1968, he cli-

**Important dates in Nixon's life**

- 1913 | January 9 | Born in Yorba Linda, California.
- 1934 | Graduated from Whittier College.
- 1940 | June 21 | Married Thelma Catherine (Pat) Ryan.
- 1942-1946 | Served in the U.S. Navy during World War II.
- 1946 | Elected to the U.S. House of Representatives.
- 1948 | Reelected to the House.
- 1950 | Elected to the U.S. Senate.
- 1952 | Elected vice president of the United States.
- 1956 | Reelected vice president.
- 1960 | Defeated for president by John F. Kennedy.
- 1968 | Elected president of the United States.
- 1972 | Reelected president.
- 1974 | August 9 | Resigned as president.
- 1994 | April 22 | Died in New York City.
Within the group of vice presidents who became president, Nixon was the first who did not succeed the president under whom he had served. Nixon became vice president under Eisenhower at the age of 40. He was the second youngest man to hold that office. John C. Breckinridge was 36 when he became vice president under James Buchanan in 1857. Before Nixon was elected vice president, he was elected twice to the U.S. House of Representatives and once to the U.S. Senate.

Friends knew Nixon as a painfully sensitive man. Nixon felt especially hurt by what he considered unfair criticism. But in politics, he won fame as a tough, forceful campaigner. He liked a good fight and had a fierce determination to succeed.

Early life

Boyhood. Richard Milhous Nixon was born on Jan. 9, 1913, in Yorba Linda, California, a village 30 miles (48 kilometers) southeast of Los Angeles. He was the second of the five sons of Francis Anthony (Frank) Nixon and Hannah Milhous Nixon. Nixon's father had moved from Ohio to southern California. There he met and married Hannah Milhous, who had come from Indiana with her parents and a group of other Quakers. Frank Nixon later gave up his Methodist faith and became a Quaker. At one time or another, he worked as a streetcar conductor, a carpenter, a laborer, and a farmer.

In 1922, the Nixon family moved to East Whittier (now Whittier). There Frank Nixon opened a combination grocery store and gasoline station. Richard had four brothers, Harold (1909-1932), Donald (1914-1987), Arthur (1918-1923), and Edward (1930- ).

At the age of about 10, Richard began working part-time as a bean picker. During his teens, he worked as a handyman in a packing house, janitor at a swimming pool, and Barker at an amusement park. While in college, he served as bookkeeper and as manager of the vegetable department of his father's store.

Education. Nixon attended elementary schools in Yorba Linda, Whittier, and nearby Fullerton. At Whittier High School, history and civics were his favorite subjects. An excellent student, he also played football and starred in debating. At the age of 17, Nixon entered Whittier College, a Quaker institution. He won several debating awards, and he became president of the student body.

The world of President Nixon

Antiwar protests on college campuses and elsewhere disrupted the nation during the late 1960's and early 1970's. The women's liberation movement gained strength. In 1973, in Roe v. Wade, the Supreme Court ruled that the U.S. Constitution allows a woman to decide for herself if she will have an abortion in the first three months of pregnancy. Concern for the environment developed as air and water pollution became increasingly serious problems. Golda Meir, a former Milwaukee schoolteacher, became prime minister of Israel in 1969. She served until 1974. School desegregation rulings by federal courts in the early 1970's resulted in the busing of students from one neighborhood to another in a number of U.S. cities.

China joined the United Nations in 1971. The minimum voting age in all U.S. elections was lowered from 21 to 18 by the 26th Amendment to the Constitution, ratified in 1971. Civil war in Pakistan in 1971 resulted in the creation of Bangladesh from the territory that had been East Pakistan. Revolution in Chile in 1973 led to the death of President Salvador Allende. Allende had been the first Marxist elected democratically to head a nation in the Western Hemisphere. The fourth Arab-Israeli war erupted in October 1973, when Egypt and Syria attacked Israel. An Arab oil embargo reduced supplies of petroleum to the United States and other nations in 1973 and 1974. Watergate stunned the nation as it developed into the biggest political scandal in U.S. history. It led to the resignations of top White House aides and, eventually, Nixon himself.

Richard Nixon's birthplace was this small frame house in Yorba Linda, California. He was the second of the five sons of Francis Anthony (Frank) Nixon and Hannah Milhous Nixon.
Nixon graduated from Whittier in 1934 and won a scholarship from the Duke University School of Law in Durham, North Carolina. Walter F. Dexter, then president of Whittier College, wrote in a letter of recommendation for Nixon: "I believe he will become one of America’s important, if not great, leaders." At Duke, Nixon was elected president of the student law association. He also won election to the Order of the Coif, the national law fraternity for honor students. Nixon ranked third in the 1937 graduating class of 44 students.

**Lawyer.** The Great Depression still gripped the United States when Nixon left Duke. There were few jobs. Nixon tried unsuccessfully to join the Federal Bureau of Investigation and then a law firm in New York City. He finally returned home and joined a Whittier law firm, in which he became a partner. Nixon and several investors later formed a company to make and market frozen orange juice, but it went bankrupt in 18 months. At the age of 26, Nixon became the youngest member of the Whittier College Board of Trustees.

**Nixon’s family.** Shortly after returning to Whittier, Nixon met Thelma Catherine Ryan (1912-1993). She had been born in a mining camp at Ely, Nevada. Her father nicknamed her Pat because she was born on the eve of St. Patrick’s Day. When Pat was a baby, her parents moved to a farm in California. They died before Pat finished high school. Pat put herself through the University of Southern California, occasionally working as an extra in Hollywood films.

When Nixon met Pat, she was teaching commercial subjects at Whittier High School. They met during try-outs for a community theater play. They were married on June 21, 1940. The Nixons had two daughters, Patricia (Tricia), born in 1946, and Julie, born in 1948. Julie married David Eisenhower, grandson of former President Eisenhower, in 1968. Tricia married Edward Cox in 1971.

**Naval officer.** In January 1942, during World War II, Nixon left Whittier to take a job in the tire rationing section of the Office of Price Administration in Washington, D.C. Eight months later, he joined the Navy as an ensign. Nixon served in a naval air transport unit in the Pacific and was promoted to lieutenant commander before the war ended in 1945.

**Career in Congress**

Since 1936, the voters of Nixon’s home congressional district had elected a Democrat, Jerry Voorhis, to the U.S. House of Representatives. Republican leaders searched for a “new face” to oppose Voorhis in the 1946 election. Nixon, then awaiting discharge from the Navy, convinced a number of leading Republicans that he was the best candidate.

Professional politicians gave Nixon little chance of defeating Voorhis, a veteran campaigner. But Nixon campaigned aggressively, implying that Voorhis was supported by Communists, though there was little evidence to prove that he was. Nixon won the election.

**U.S. representative.** In the House of Representatives, Nixon was proudest of his work on a committee that laid the groundwork for the Marshall Plan and other foreign aid programs (see Foreign aid). Nixon helped write the Taft-Hartley Act, which established controls over labor unions. In addition, he became a member of the House Committee on Un-American Activities.

In 1948, Nixon was reelected to the House. The Alger Hiss case, which began that same year, brought Nixon into national prominence. Hiss, a former State Department official, was accused of having passed classified State Department documents to a Soviet spy ring during the 1930’s. The matter rested with Hiss’s word against that of his accusers. Many members of the Un-American Activities Committee wanted to drop the case, but Nixon insisted that Hiss was a traitor. The question of Communists in government was a fierce political issue at the time. In 1950, a federal District Court jury convicted Hiss of perjury in denying that he had ever given secret documents to Soviet agents. See Hiss, Alger.

**U.S. senator.** In 1950, at the peak of his prominence in the Hiss case, Nixon ran for the U.S. Senate. He opposed Representative Helen Gahagan Douglas, a New Deal Democrat. During the campaign, Nixon emphasized charges, made originally by Douglas’s foes in the Democratic primary election, that she was “soft” on Communism. He called her the “Pink Lady.” Douglas gave too much to labeling Nixon “Tricky Dick.” In one of California’s most savage political contests, Nixon defeated Douglas by nearly 700,000 votes.

In the Senate, Nixon served on the Labor and Public Welfare Committee. He also became a popular speaker at Republican Party affairs and at civic meetings in all parts of the United States.

**The 1952 campaign.** In 1952, the Republican National Convention nominated Nixon for vice president to run with General Dwight D. Eisenhower. A highlight of the campaign was a dispute over an $18,000 fund set up by Nixon’s supporters in California. They had organized the fund in 1950 to enable Nixon to campaign for Republican programs and candidates in both election and non-election years. Nixon and his friends showed that they had used the money only for political expenses, but members of the media labeled it a “secret slush fund.” Many Republicans, fearing that Nixon might hurt Eisenhower’s chances of victory, demanded that Nixon withdraw from the ticket.

Representative Nixon won national attention during the Alger Hiss case. He worked with Whittaker Chambers, left, who accused Hiss of spying, and investigator Robert Stripling, right.

*UPI/Bettmann Newsphotos*
Nixon's cause seemed hopeless. Then, on Sept. 23, 1952, Nixon stated his case in an emotional address over television and radio. He discussed his personal finances in detail, showing that he had not profited personally from the fund. He said that "Pat doesn't have a mink coat. But she does have a respectable Republican cloth coat." And he vowed to keep Checkers, a cocker spaniel that had been a gift to his daughters. After the program, Republicans hailed Nixon as a hero. Eisenhower put his arm around Nixon when they next met and declared, "You're my boy."

During the campaign, Nixon accused his Democratic opponents of not recognizing the Communist threat to the United States and the world. He charged that a vote for the Democrats was a vote for socialism at home and surrender abroad. Eisenhower and Nixon went on to defeat their Democratic opponents, Governor Adlai E. Stevenson of Illinois and Senator John J. Sparkman of Alabama.

Vice president (1953-1961)

Eisenhower succeeded Democratic President Harry S. Truman in 1953. He gave Nixon the job of working with members of Congress to smooth out possible quarrels with the new administration. Eisenhower also assigned Nixon to preside over Cabinet meetings and the National Security Council in the president's absence. Nixon took a greater role in the executive branch of the government than any previous vice president.

Eisenhower's illnesses. Nixon's biggest test as vice president began Sept. 24, 1955, when Eisenhower suffered a heart attack. Nixon calmly went about his normal duties, presided at Cabinet meetings, and kept the wheels of government moving smoothly. He also stepped in when the president suffered another illness in June 1956 and a stroke in November 1957. The arrangement Nixon worked out with Eisenhower later served as a basis for the 25th Amendment to the Constitution of the United States. The amendment, ratified in 1967, provides for the vice president acting for the president when the president is unable to perform the duties of the office.

The 1956 election. Many people wondered whether Eisenhower would ask Nixon to run with him again in 1956. For a while, the president seemed to be considering the idea of dropping his controversial running mate. Finally, however, the president declared: "Anyone who attempts to drive a wedge of any kind between Dick Nixon and me has just as much chance as if he tried to drive it between my brother and me." Eisenhower and Nixon defeated the Democratic nominees, Adlai E. Stevenson and Senator Estes Kefauver of Tennessee.

Overseas missions. Nixon frequently acted as spokesperson for the government on trips to other nations. As vice president, he toured nearly 60 countries, visiting every continent except Antarctica. During a tour of Latin America in the spring of 1958, Nixon faced violence and danger. In Peru, Communist agents led groups that booed and stoned him and even spit at him. In Venezuela, mobs smashed the windows of Nixon's car. However, he was not hurt.

Nixon traveled to the Soviet Union in July 1959 to open an American exhibit in Moscow. As he and Premier Nikita S. Khrushchev walked through a model home, they argued over which economic system was better, capitalism or Communism. At one point in the "kitchen debate," Nixon startled his hosts by pointing his finger at Khrushchev and saying bluntly: "You don't know everything."

The presidential campaign was close and hard-fought from start to finish. Kennedy argued that Republican
methods had slowed U.S. economic growth, contributing to what he called a loss of American prestige abroad. Nixon cited figures to show that the economy was growing at a satisfactory rate. Kennedy also charged that the Republicans had allowed the Soviet Union to overtake the United States in missile production.

Nixon and Kennedy took part in a unique series of four televised debates. The television and radio audiences included most of the nation's voters. These "great debates" marked the first time in U.S. history that presidential candidates argued campaign issues face-to-face. Kennedy's calm manner and appearance in the first debate, contrasted with Nixon's apparent nervousness, helped Nixon win over many voters who had been undecided about their choice.

Nixon lost to Kennedy in one of the closest presidential elections in U.S. history. Kennedy won by 114,673 popular votes out of nearly 69 million total votes. Nixon carried 26 states to 22 for Kennedy, but Kennedy received 303 electoral votes compared to Nixon's 219. Senator Harry F. Byrd of Virginia got 15 electoral votes. Widespread charges of fraudulent vote counting in Illinois and Texas cast some doubt on Kennedy's victory.

**Political comeback**

**Defeat in California.** In 1961, Nixon began to practice law in Los Angeles. In 1962, he decided to run for governor of California. Nixon won the Republican nomination for governor by defeating Joseph C. Shell in the state primary election. But the victory was costly. Conservative Republicans had supported Shell, and Nixon's triumph split the party. In the election, California's governor, Democrat Edmund G. (Pat) Brown, beat Nixon by about 300,000 votes.

**New York City lawyer.** Nixon moved to New York City in 1963 and began a new law practice. He became a partner in a Wall Street law firm, and his associates placed his name first in the list of partners.

Some of Nixon's supporters wanted him to run for president in 1964, but Nixon felt that most Republicans favored Senator Barry M. Goldwater of Arizona. Goldwater won the Republican presidential nomination, and Nixon campaigned for him and other party candidates. President Lyndon B. Johnson, seeking his first full term, defeated Goldwater by a huge margin.

Goldwater's overwhelming defeat put Nixon back into the political limelight. Liberal and conservative Republicans were quarreling bitterly, and Nixon was the only nationally prominent man whom both groups could accept. In 1966, Nixon campaigned vigorously for Republican candidates in congressional elections. Republicans won 47 House seats and 3 Senate seats that had been held by Democrats. Nixon received much credit for the Republican victories.

In 1967, Nixon traveled around the world. His trip included visits to the Soviet Union and South Vietnam.

**The 1968 election.** In February 1968, Nixon announced that he would be a candidate for the Republican presidential nomination. Many Republicans wondered whether he could regain his voter appeal. They feared that his defeats by Kennedy and Brown had given him the image of a loser. But Nixon won primary elections by large margins in New Hampshire, Wisconsin, Indiana, Nebraska, Oregon, and South Dakota.

Nixon's chief opponents for the presidential nomination were Governors Nelson Rockefeller of New York, and Ronald Reagan of California. But Nixon easily won nomination on the first ballot at the Republican National Convention in Miami Beach. The convention nominated Nixon's choice as running mate, Governor Spiro T. Agnew of Maryland.

The Democrats chose Vice President Hubert H. Humphrey and Senator Edmund S. Muskie of Maine. Former Governor George C. Wallace of Alabama and retired General Curtis E. LeMay ran as the candidates of the American Independent Party.

Both Nixon and Humphrey promised to make peace in Vietnam their main goal as president. The Vietnam War had begun in 1957 as a battle for control of South Vietnam between South Vietnam's non-Communist government and the Communist-led National Liberation Front, the Viet Cong. By the mid-1960's, the United States was deeply involved in the war as an ally of the South Vietnamese government.

Nixon called for a program of what he termed "new internationalism." Under this program, other nations would take over from the United States more of the responsibility for preserving world peace and helping developing countries. This plan later became known as the Nixon Doctrine. Nixon also pledged to strengthen law enforcement in the United States.

In the election, Nixon defeated Humphrey by only about 511,000 popular votes, 31,785,148 to 31,274,503. Wallace received 9,901,151 popular votes. Nixon won a clear majority of electoral votes, with 301. Humphrey received 191 electoral votes, and Wallace got 46. For the electoral vote by states, see Electoral College (table).

**Nixon's first administration (1969-1973)**

**Foreign policy.** Nixon's major goal was settlement of the Vietnam War. In his first inaugural address, Nixon said: "The greatest honor history can bestow is the title of peacemaker. This honor now beckons America."

**The Vietnam War.** The Vietnam peace talks, begun...
1968, continued in Paris. But the negotiators made little progress. In March 1969, Nixon ordered a stepped-up training program for South Vietnamese forces so they could gradually take over the major burden of fighting. He also ordered secret bombings of supply routes in Cambodia. In July, he began a gradual withdrawal of U.S. combat troops from Vietnam, a policy known as Vietnamization. Many Americans favored it, but many others wanted U.S. involvement to end immediately. Protests and demonstrations swept the nation.

In 1970, United States troops invaded Cambodia to attack North Vietnamese supply depots there. Nixon said he action would shorten the war, but many people felt it was expanding it. Protests broke out on hundreds of college campuses. At Kent State University in Ohio, National Guardsmen fired into a crowd of demonstrators, killing four students and wounding nine others. The shocked reaction of the nation and student strikes at other colleges, many of which closed until fall, forced Nixon to cut short the Cambodian campaign.

In May 1972, in response to a Communist offensive, Nixon ordered a blockade of North Vietnam to cut off its war supplies from the Soviet Union and China. The blockade included the mining of North Vietnam's ports and the bombing of its rail and highway links to China. In December 1972, after peace negotiations broke down, Nixon ordered extensive bombing of Hanoi, the North Vietnamese capital.

**Relations with China.** In 1969, Nixon approved the removal of some restrictions on travel by Americans to China. He also encouraged the reopening of trade between China and the United States. The two nations had stopped trading with each other during the Korean War (1950-1953). In 1971, Nixon approved the export of certain goods to China. In February 1972, the president visited China for seven days, and he began the process that led to formal recognition of China by the United States in 1979.

**Relations with the Soviet Union.** In May 1972, Nixon visited the Soviet Union for nine days. During this visit, Nixon and Leonid I. Brezhnev, leader of the Soviet Communist Party, signed agreements to limit the production of nuclear weapons. Later that year, the Soviet Union became a major buyer of U.S. wheat.

**The national scene.** In August 1969, Nixon proposed a series of major domestic reforms, which he termed the *New Federalism.* One of the reforms called for a minimum federal payment to every needy family with children. Nixon also called for a form of national health insurance and suggested a *revenue sharing* plan in which the federal government would share its tax revenues with state and local governments. But action on the reforms was stalled as key Democrats and Republicans in Congress asked for major changes.

**Major legislation.** In spite of the legislative slowdown, Congress did enact several far-reaching laws. In 1969, it passed Nixon's proposal to establish a lottery system for the draft.

**Vice presidents and Cabinet**

- Vice president: Spiro T. Agnew
- Secretary of state: William P. Rogers
- Secretary of the treasury: David M. Kennedy
- Secretary of defense: Melvin R. Laird
- Attorney general: John N. Mitchell
- Postmaster general: Winton M. Blount
- Secretary of the interior: Walter J. Hickel
- Secretary of agriculture: Clifford M. Hardin
- Secretary of commerce: Maurice H. Stans
- Secretary of labor: George P. Shultz
- Secretary of health, education, and welfare: Robert H. Finch
- Secretary of housing and urban development: George W. Romney
- Secretary of transportation: John A. Volpe

---

Nixon, Richard Milhous 433

* * Has a biography in World Book.

*Reduced to non-Cabinet rank, 1971.

Nixon toured the Great Wall of China during his historic visit to that country in 1972. Relations between the United States and China improved dramatically during Nixon's presidency.

the military draft. Also in 1969, Congress approved extensive reforms in federal tax laws. These reforms included increases in personal income tax deductions and cuts in tax benefits for foundations and oil companies. In 1970, Congress established independent agencies to replace the Post Office Department and to operate the passenger trains that linked the nation's major cities. Also in 1970, Congress approved the lowering of the minimum voting age in federal elections to 18. It began the process that led to the ratification in 1971 of the 26th Amendment to the U.S. Constitution, which set the voting age at 18 for elections. In 1972, Congress approved Nixon's revenue sharing program. The legislation provided billions of dollars in federal tax money to state and local governments.

Inflation was one of Nixon's chief domestic concerns. Many Americans found that although they were earning more money than ever before, rising prices sharply cut their gains. In 1971, Nixon, concerned about how the economy might affect his re-election, set up a Pay Board to stop inflationary wage and salary increases and a Price Commission to regulate price and rent increases. The economy improved in 1972. In addition, the inflation rate slowed.

The ABM system. In March 1969, Nixon proposed a plan to build an antiballistic missile (ABM) system called Safeguard. Nixon said the new missiles were needed to protect U.S. underground missiles and bomber bases from enemy missile attack and to match comparable systems in the Soviet Union. The plan became one of the most heavily debated issues of Nixon's administration. Critics charged that the system would step up the arms race between the United States and the Soviet Union. They also claimed the new missiles would cost too much money and fail to destroy enemy missiles. In August, the Senate narrowly approved construction of the two ABM bases Nixon had requested.

Civil rights. Nixon developed a successful "Southern strategy" that resulted in virtually all the Southern States switching from Democratic to Republican during his time in office. The Democrats were perceived to be the party of civil rights and desegregation, while Nixon's Republicans appeared to be more supportive of the interests of Southerners not in favor of desegregation. For example, Republicans fiercely opposed the Supreme Court's 1971 ruling that children could be bused to integrate public schools. However, it was during Nixon's administration that legal segregation in Southern schools was finally ended. In addition, Nixon introduced the Philadelphia Plan, an affirmative action program for hiring in companies with large government contracts.

Supreme Court nominations. In 1969, Nixon's appointment of Warren E. Burger as chief justice of the United States was approved. However, in that same year and again in 1970, Nixon suffered a stinging defeat when he tried to appoint a conservative Southerner to the Supreme Court. In May 1969, Associate Justice Abe Fortas resigned from the court under charges of personal misconduct (see Fortas, Abe). Nixon nominated Judge Clement F. Haynsworth, Jr., of South Carolina to succeed Fortas. Some critics claimed that Haynsworth was anti-black. Others charged he was unethical for ruling in a case in which he had a financial interest. In November, the Senate rejected the nomination by a 53 to 45 vote.

In January 1970, Nixon nominated Judge G. Harrold Carswell of Florida for the seat. Opposition to Carswell grew quickly after several judges and law school deans rated him unqualified for the Supreme Court. In April, the Senate defeated the nomination by a 51 to 45 vote. It was the first time that two Supreme Court nominees of president had been rejected since 1894, when Grover Cleveland was president.

After Carswell's defeat, Nixon charged that the Senate would not confirm a Southerner to the court. In May, the Senate unanimously approved Nixon's third choice, Judge Harry A. Blackmun of Minnesota. In 1971, the Senate approved Nixon's selection of Lewis F. Powell, Jr., and William H. Rehnquist for the court.

The U.S. space program opened a new era of exploration and discovery in 1969. On July 20, Apollo 11 astronauts Neil A. Armstrong and Buzz Aldrin became the first people to set foot on the moon. Through a special telephone connection while they were on the moon Nixon told them, "Because of what you have done, the heavens have become part of man's world."

Environmental problems attracted more and more attention during Nixon's administration. Many Americans began to realize that pollution of the air, land, and water endangered not only the quality of life but also life itself. In 1970, Nixon set up the Environmental Protection Agency to deal with pollution problems.

In addition, although Nixon was not known to be an environmentalist, he approved of the Clean Air Act Amendments, the Coastal Zone Management Act, the
Marine Mammal Protection Act, the Endangered Species Act, and the Safe Drinking Water Act. He also transferred land to the states for 642 new parks.

In the election, Nixon won a landslide victory. He received almost 18 million more popular votes than McGovern—the widest margin of any U.S. presidential election. Nixon got 520 electoral votes, and McGovern received 17. John Hospers of the Libertarian Party won 1 electoral vote. See Electoral College (table).

Life in the White House. The Nixons brought a calm and reserved way of life to the White House. They preferred formal dress, including white ties and coats with tails for men and long gowns for women. They also favored fox trots and waltzes for dancing.

The Nixons' taste in art also was conservative. They replaced a number of the op art paintings on White House walls with traditional landscapes and portraits. Nixon was the first president to play the piano since Harry Truman. He occasionally played for guests. Nixon followed sports closely and impressed many visitors with his knowledge of baseball and football.

Pat Nixon worked hard to encourage Americans to volunteer to help deal with the country’s social problems. She frequently traveled across the nation to support volunteer organizations.

A private man, Nixon did much of his work in a remote office in the Executive Office Building across from the White House. Shortly after taking office, he bought an estate in San Clemente, a beach resort in southern California. It became known as the Western White House because Nixon spent working vacations there. He also maintained a home in Key Biscayne, Florida.

Nixon’s second administration (1973-1974)

Foreign affairs. On Jan. 27, 1973, the United States and the other participants in the Vietnam War signed agreements to stop fighting immediately and begin exchanging prisoners. The agreements climaxd several weeks of bargaining between North Vietnamese officials and Henry A. Kissinger, Nixon’s national security adviser, who had begun secret talks with the Communists in 1969. The United States completed its troop withdrawal from South Vietnam in March. Nixon privately assured South Vietnam that the United States would use “full force” to aid the South Vietnamese if the Communists violated the agreements. Fighting did continue in 1973, but no U.S. troops reentered the war. Later that year, Kissinger became secretary of state.

Nixon continued his efforts to improve relations between the United States and China. In 1973, the two nations sent representatives to serve in each other’s capital and exchanged visits by cultural groups.

Events at home. Nixon carried out a key campaign pledge in January 1973 when he ended the military draft. The military then became an all-volunteer force.

Disputes with Congress. Nixon’s relations with the Democratic-controlled Congress grew increasingly strained during 1973. Nixon angered many members of Congress by impounding (not spending) several billion dollars in federal aid on projects that Congress had approved. Nixon called the projects wasteful.

The president suffered a major defeat when Congress forced him to end U.S. bombing in Cambodia. Nixon had argued that the bombing was needed to prevent a Com-
munist take-over of that nation. But Congress refused to provide money for bombing beyond Aug. 15, 1973.

Nixon received another major setback in 1973 when Congress overrode his veto of a resolution that limited presidential war powers. The War Powers Resolution gives Congress the power to halt after 60 days the use of any U.S. armed forces that the president has ordered into combat abroad. Passage of the resolution was the strongest action ever taken by Congress to spell out the warmaking powers of Congress and the president.

Economic problems continued to challenge Nixon in 1973. In January, he ended most of the government-required limits that had been placed on wage and price increases in 1971. But prices soared, and another brief use of controls resulted in a shortage of beef and other foods. By the end of 1973, inflation had risen 8.8 percent, the largest increase in any year since 1947.

Also in 1973, a fuel shortage led to reduced supplies of oil for home heating and industry and to gasoline rationing in a number of states. In 1974, Congress approved Nixon's proposal to set up a Federal Energy Administration to deal with the energy shortage.

The Watergate scandal hit the Nixon administration during 1973. It arose from a break-in at the Democratic Party headquarters in the Watergate building complex in Washington, D.C., on June 17, 1972. Employees of Nixon's 1972 reelection committee were arrested in the break-in and convicted of burglary. Early in 1973, evidence was uncovered that linked several top White House aides with either the break-in or later attempts to hide information related to it.

Nixon insisted that he did not participate in the Watergate break-in or the cover-up. In addition, he promised a full investigation of the case. In May, Archibald Cox, a Harvard Law School professor, was named to head the investigation as the special prosecutor.

In July, a Senate investigating committee learned that Nixon had secretly made tape recordings of conversations in his White House offices since 1971. The president said that he taped the conversations to preserve an accurate record of his administration. Cox and the Senate committee asked Nixon to give them certain tapes that they believed could aid their investigations. Nixon refused. He argued that the Constitution gives a president the implied right to maintain the confidentiality of private presidential conversations. Nixon said the loss of that right would endanger the presidency.

In August, Cox and the committee filed petitions in court to obtain the tapes. U.S. District Court Judge John Sirica decided to review the tapes himself and ordered Nixon to give them to him. Nixon appealed the order, but a U.S. court of appeals supported Sirica.

On October 19, Nixon offered to supply summaries of the tapes to the Senate committee and to Cox. Cox refused, arguing that summaries would not be regarded as proper evidence in court. Nixon ordered Attorney General Elliot L. Richardson to fire Cox, but Richardson refused and resigned, as did Deputy Attorney General William G. Ruckelshaus. Nixon named Robert H. Bork acting attorney general, and Bork fired Cox. Leon Jaworski, a noted Texas attorney, later succeeded Cox. But Nixon's actions resulted in a move for his impeachment.

The resignation of Agnew on Oct. 10, 1973, further stunned the nation. Earlier that year, federal officials had begun to investigate Agnew in connection with charge of graft in Maryland. They uncovered evidence he had accepted illegal payments as an officeholder in Maryland and as vice president. After he resigned, Agnew pleaded nolo contendere (no contest) to a charge that he had cheated on his federal income tax payment for 1967.

Quotations from Nixon
The following quotations come from some of Richard Nixon's speeches and writings.

Crises can indeed be agony. But it is the exquisite agony which a man might not want to experience again—you would not for the world have missed.

Introduction to Six Crises, published in 1962

We have found ourselves rich in goods, but rugged in spirit; reaching with magnificent precision for the moon, but falling into raucous discord on earth. We are caught in war, wanting peace. We are torn by divisions, wanting unity.

Speech announcing invasion of Cambodia, April 30, 1970

If when the chips are down, the world's most powerful nation ... acts like a pitiful, helpless giant, the forces of totalitarianism and anarchy will threaten free nations ... throughout the world.

Speech announcing invasion of Cambodia, April 30, 1970

Let us reject the narrow visions of those who would tell us that we are evil because we are not yet perfect ... that all the sweat and toil and sacrifice that have gone into the building of America were for naught because the building is not yet done. Let us see that the path we are traveling is wide, with room in it for all of us, and that its direction is toward a better nation in a more peaceful world.

State of the Union Address to Congress, Jan. 20, 1972

Always give your best, never get discouraged, never be petty; always remember, others may hate you. Those who hate you don't win unless you hate them. And then you destroy yourself.

Final speech before leaving office, Aug. 9, 1974

During the Watergate scandal, Nixon appeared on TV with transcripts of tape recordings of White House conversations. He refused to give the actual tapes to investigators.
years later, in 1981, a Maryland court ordered Agnew to say the state the amount of the bribes it declared he had accepted, plus interest. In 1983, Agnew paid $268,482.

Nixon became the first president to appoint a vice president under procedures established by the 25th amendment to the Constitution. He named House Majority Leader Gerald R. Ford as Agnew's successor, and Ford became vice president on Dec. 6, 1973.

The impeachment hearings began before the House Judiciary Committee in October 1973. The committee had obtained from the president several tapes and edited transcripts of many tapes of White House conversations. The committee issued subpoenas (legal demands) or additional tapes, but the president resisted and took his case to the Supreme Court.

In July 1974, before the court made its decision, a majority of the committee members voted to recommend articles of impeachment against Nixon. The first article charged that the president obstructed justice by withholding evidence, counseling his aides to give false testimony, and otherwise interfering with the Watergate investigation. The second impeachment article charged that Nixon abused presidential powers, and the third accused him of refusing to obey subpoenas.

In late July, the Supreme Court ruled that Nixon had to turn over the tapes. Nixon made the tapes public on Aug. 5. One tape revealed that he had spoken of a cover-up as early as June 23, 1972, six days after the burglary. Republican congressional leaders warned Nixon that he faced almost certain impeachment by the House of Representatives and removal from office by the Senate.

Resignation and pardon. Nixon told his family on August 7 that he planned to resign. He announced his decision to the American people in a nationwide television address the next evening. On August 9, with about 2 1/2 years remaining in his second term, Nixon submitted his resignation as president. At noon that day, Vice President Gerald R. Ford was sworn in as the 38th president.

Nixon's resignation ended the prospect of a struggle over impeachment. But many Americans continued to debate whether he should be prosecuted for his role in the cover-up. On September 8, Ford granted Nixon a pardon for all federal crimes Nixon may have committed while president. Ford said he made the decision to " reconcile divisions in our country and heal the wounds that had festered too long."

Later years

After leaving office, Nixon returned to San Clemente. He avoided active participation in politics and spent much of his time playing golf and writing. Nixon maintained a strong interest in international affairs, and his opinions on U.S. foreign policy were highly regarded by many people, including both Democratic and Republican presidents who served after him.

In 1990, the Richard Nixon Library and Birthplace opened in Yorba Linda, California. It includes a museum. Nixon's wife, Pat, died of lung cancer on June 22, 1993, at their home in Park Ridge. On April 18, 1994, Nixon suffered a stroke at home just before dinner and was taken by ambulance to a hospital in New York City. Three days later, he lapsed into a coma. He died the following day, April 22. Nixon and his wife are buried on the grounds of the Richard Nixon Library and Birthplace, near the house he was born in.

What was Vietnamization? The New Federalism?
Why did Nixon resign from the presidency?

Additional resources

Nizhniy Novgorod, NHZH ne NAHV guh RAHD, (pop. 1,361,500), is an industrial center in Russia. It lies at the fork of the Volga and Oka rivers (see Russia [political map]). Nizhniy Novgorod is one of the oldest cities in Russia and is known as the Cradle of the Russian Empire. The city's upper part contains a fortress and historic cathedrals. The lower town is the industrial section. One of Russia's largest automobile factories is in Nizhniy Novgorod. Other products include locomotives, airplanes, machine tools, and chemicals.

Nizhniy Novgorod was an important commercial center in the Middle Ages, a period in history that lasted from about the 400's through the 1400's. In this period, west-east travel along the Oka River and through a low pass in the Ural Mountains met north-south travel on the Volga River. In 1322, when Russia was a republic of the Soviet Union, the city was renamed Gorki in honor of the Russian writer Maxim Gorki. The city was renamed Nizhniy Novgorod in 1990, about a year before the Soviet republics became independent.

No-fault insurance is a type of automobile accident insurance that was first proposed in the 1960's. It provides that if a driver, passenger, or pedestrian is injured in an accident—usually the driver's company—must pay, no matter who caused the accident. Injured people receive payment for medical costs and loss of income. However, many no-fault plans restrict a victim's right to sue for pain and suffering or other nonfinancial damage. Such restrictions forbid a suit for nonfinancial damage unless the medical expenses exceed a certain amount or the victim was disfigured, disabled, or killed. Many other types of insurance, including fire, health, and life insurance, have always been no-fault.

Supporters of no-fault automobile insurance believe that it eliminates many of the problems caused by people who sue each other for injuries. Supporters of no-fault automobile insurance believe that it eliminates many of the problems caused by people who sue each other for injuries. No-fault insurance is a type of automobile accident insurance that was first proposed in the 1960's. It provides that if a driver, passenger, or pedestrian is injured in an accident—usually the driver's company—must pay, no matter who caused the accident. Injured people receive payment for medical costs and loss of income. However, many no-fault plans restrict a victim's right to sue for pain and suffering or other nonfinancial damage. Such restrictions forbid a suit for nonfinancial damage unless the medical expenses exceed a certain amount or the victim was disfigured, disabled, or killed. Many other types of insurance, including fire, health, and life insurance, have always been no-fault.
In 1970, Massachusetts became the first state to adopt no-fault insurance plan. A number of other states later adopted no-fault plans. Some had modified plans, without restricted suits. Dan R. Anderson

To play. See Drama (Asian drama); Japanese literature (the medieval period).

Joah, NOH uh, according to the Bible, was the only righteous, God-fearing man of his time. Genesis 6:9 tells that he was chosen by God to keep some people and animals alive during the Deluge, or great Flood. Noah warned people for 120 years that the Flood was coming. During that time, he built a ship, called the ark, which was 450 feet (137 meters) long. He took into the ark his family, and enough birds and animals to repopulate the earth. The rain poured for 40 days and 40 nights (Gen. 8:1-9).

The waters dropped enough 150 days after the Flood started that the ark was able to rest on the mountains of Ararat (see Ararat). Noah let loose a raven that did not return. Then he sent out a dove, and it returned because it found no place to perch. He sent out the dove two more times. On the second flight, it returned with a live branch in its mouth.

Noah and the animals left the ark later to begin a new life. Noah offered sacrifice to God for deliverance, and God promised him that He would never send another flood to destroy the earth. He made the rainbow a sign of that promise. He commanded Noah and his descendants to respect human life and to punish murder with the death penalty.

Noah's sons were Shem, Ham, and Japheth. Shem became father of the Semitic peoples, including the Jews and the Arabs. Ham was the father of the Hamitic peoples. Japheth became the father of peoples of Asia Minor and Europe. In traditions originally unrelated to the flood, Noah is pictured as a gardener and is credited with the discovery of wine (Gen. 9:18-27).

Carole R. Fontaine

Obel, noh BEHL, Alfred Bernhard (1833-1896), a Swedish chemist and industrialist, invented dynamite. He established the Nobel Prizes, using profits from the manufacture of chemical explosives to provide funds for the prizes (see Nobel Prizes).

Nobel began experimenting with nitroglycerin in his father's factory. Liquid nitroglycerin is a powerful explosive that is dangerous because of its tendency to explode when handled roughly. Nobel tried many ways of using nitroglycerin safe to use. The best way, he discovered, was to mix it with a fine, porous powder called eselguhr: Nobel named the resulting powdery mixture dynamite (see Dynamite). He received a patent for it in 1867. Construction and mining companies and the military ordered large quantities of dynamite because of its latent safety and explosive power. Nobel set up factories around the world, and sales of dynamite and other explosives bought him great wealth.

His other chemical research provided valuable information on the preparation of artificial forms of rubber, leather, silk, and precious stones.

Nobel was born on Oct. 21, 1833, in Stockholm and was educated in St. Petersburg, Russia, where his family had moved in 1842. He traveled widely as a young man and became fluent in five languages. Nobel was greatly interested in literature and wrote poetry, novels, and plays in his spare time. In his will, Nobel set up a fund of about $9 million. The interest from the money was to be used to award annual prizes to people whose work most benefited humanity. Nobel wanted the profits from explosives to be used to reward human ingenuity. The Nobel Prizes, first awarded in 1901, remain the most honored prizes in the world.

Melvyn C. Usselman

Additional resources

Nobel Prizes, noh BEHL, are awarded each year to people, regardless of nationality, who have made valuable contributions to the "good of humanity." In his will, the Swedish inventor Alfred Nobel directed that the income from his $9-million estate be used to fund five annual prizes. The awards are given for the most important discoveries or inventions in the fields of physics, chemistry, and physiology or medicine; the most distinguished literary work of an idealistic nature; and the most effective work in the interest of international peace. The prizes were first presented in 1901. A sixth prize—the Bank of Sweden Prize in Economic Sciences in Memory of Alfred Nobel—was first awarded in 1969. This prize was established by the Bank of Sweden and is funded by the bank. The value of each of the six prizes is about $1 million.

The Royal Swedish Academy of Sciences in Stockholm, Sweden, chooses the physics, chemistry, and economics winners. The Nobel Assembly at the Karolinska Institute in Stockholm awards the prize for medicine. The Swedish Academy in Stockholm awards the prize for literature. The Norwegian Nobel Committee elected by the Norwegian Storting (parliament) awards the prize for peace.

A candidate may not apply directly for a prize. A qualified person must submit each name in writing. For the literary prize, the Swedish Academy considers only works that have appeared in print. The academy usually selects an author for his or her complete work rather than for one book.

The organizations that award the prizes appoint 15 deputies who elect a board of directors. The board holds office for two years and administers the funds. Prizewinners receive their awards on December 10, the anniversary of the death of Alfred Nobel. The peace prize is awarded in Oslo, Norway. The other prizes are presented in Stockholm. Two or three people may share a prize. Sometimes, prizes are not awarded or are awarded in a later year.

Critically reviewed by the Nobel Foundation
There is a biography in World Book of each prizewinner whose name is marked with an asterisk in the tables on the following pages.
Nobel Prizes consist of a medal and a cash award. Prizes are awarded for achievement in chemistry, physics, physiology or medicine, literature, world peace, and economics. The front side of each medal has a bust of Alfred Nobel, a Swedish chemist who established most of the prizes in the late 1800’s. The bust is the same on the physics and chemistry, physiology or medicine, and literature medals, shown here. The physics and chemistry medals have identical back sides. The front and back sides of the peace and economics medals are shown at the far right.

Nobel Prizes in physics

1901 *Wilhelm C. Roentgen (German) for discovering X rays.
1902 *Hendrik Antoon Lorentz and *Pieter Zeeman (Dutch) for discovering the Zeeman effect of magnetism on light.
1903 *Antoine Henri Becquerel (French) for discovering natural radioactivity and *Pierre and Marie Curie (French) for their research on radiation.
1904 Baron Rayleigh (British) for studying the density of gases and discovering argon.
1905 Philipp Lenard (German) for studying the properties of cathode rays.
1906 *Sir Joseph John Thomson (British) for studying electrical discharge through gases.
1907 *Albert A. Michelson (American) for his design of precise optical instruments and for the accurate measurements he obtained with them.
1908 Gabriel Lippmann (French) for his method of color photography.
1909 *Guglielmo Marconi (Italian) and Karl Ferdinand Braun (German) for developing the wireless telegraph.
1910 Johannes D. van der Waals (Dutch) for studying the relationships of liquids and gases.
1911 Wilhelm Wien (German) for his discoveries on the heat radiated by black objects.
1912 Nils Dalén (Swedish) for inventing automatic gas regulators for lighthouses.
1913 Heike Kamerlingh Onnes (Dutch) for experimenting with low temperatures and liquefying helium.
1914 Max T. von Laue (German) for using crystals to measure X rays.
1915 *Sir William Henry Bragg and Sir William L. Bragg (British) for using X rays to study crystal structure.
1916 No award
1917 Charles Barkla (British) for studying the diffusion of light and the radiation of X rays from elements.
1918 *Max Planck (German) for stating the quantum theory of light.
1919 Johannes Stark (German) for discovering the Stark effect of spectra in electric fields.
1920 Charles E. Guillaume (French) for discovering nickel-steel alloys with slight expansion, and the alloy invar.
1921 *Albert Einstein (German) for contributing to mathematical physics and stating the law of the photoelectric effect.
1922 *Niels Bohr (Danish) for studying the structure of atoms and their radiations.
1923 *Robert A. Millikan (American) for measuring the charge on electrons and working on the photoelectric effect.
1924 *Karl M. G. Siegbahn (Swedish) for working with the X-ray spectroscope.
1925 James Franck and *Gustav Hertz (German) for stating laws on the collision of an electron with an atom.
1926 Jean Baptiste Perrin (French) for studying the discontinuous structure of matter and measuring the sizes of atoms.
1927 Arthur H. Compton (American) for discovering the Compton effect on X rays reflected from atoms, and Charles T. R. Wilson (British) for discovering a method for tracing the paths of ions.
1928 Owen W. Richardson (British) for studying thermionic effect and electrons sent off by hot metals.
1929 *Louis Victor de Broglie (French) for discovering the wave character of electrons.
1930 *Sir Chandrasekhara Venkata Raman (Indian) for discovering a new effect in radiation from elements.
1931 No award
1932 *Werner Heisenberg (German) for founding quantum mechanics, which led to discoveries in hydrogen.
1933 *Paul Dirac (British) and *Erwin Schrödinger (Austrian) for discovering new forms of atomic theory.
1934 No award
1935 *Sir James Chadwick (British) for discovering the neutron.
1936 *Carl David Anderson (American) for discovering the positron, and Victor F. Hess (Austrian) for discovering cosmic rays.
1937 Clinton Davison (American) and George Thomson (British) for discovering the diffraction of electrons by crystals.
1938 *Enrico Fermi (Italian) for discovering new radioactive elements beyond uranium.
1939 *Ernest O. Lawrence (American) for inventing the cyclotron and working on artificial radioactivity.
1940-1942 No award
1943 Otto Stern (American) for discovering the molecular beam method of studying the atom.
1944 Isidor Isaac Rabi (American) for recording the magnetic properties of atomic nuclei.
1945 *Wolfgang Pauli (Austrian) for discovering the exclusion principle (Pauli principle) of electrons.
1946 *Percy Williams Bridgman (American) for his work in the field of very high pressures.
1947 *Sir Edward V. Appleton (British) for exploring the ionosphere.
1948 Patrick M. S. Blackett (British) for his discoveries in cosmic radiation.
1949 *Hideki Yukawa (Japanese) for his prediction of the existence of mesons.
1950 Cecil Frank Powell (British) for his photographic method of studying atomic nuclei and his discoveries concerning mesons.
1951 *Sir John D. Cockcroft (British) and *Ernest T. S. Walton (Irish) for work on the transmutation of atomic nuclei by artificially accelerated atomic particles.

*Has a biography in World Book.
Nobel Prizes in physics (continued)

1952 *Felix Bloch and 'Edward Mills Purcell (American) for developing magnetic measurement methods for atomic nuclei.
1953 Frits Zernike (Dutch) for inventing the phase contrast microscope for cancer research.
1954 *Max Born (German) for research in quantum mechanics, and Walther Bothe (German) for discoveries he made with his coincidence method.
1955 *Willis E. Lamb, Jr. (American) for discoveries on the structure of the hydrogen spectrum, and Polikarp Kusch (American) for determining the magnetic moment of the electron.
1957 *Tsung Dao Lee and *Chen Ning Yang (American) for work disproving the law of conservation of parity.
1958 Pavel A. Cherenkov, Ilya M. Frank, and Igor Y. Tamm (Soviet) for discovering and interpreting the Cherenkov effect in studying high-energy particles.
1959 Emilio Segrè and Owen Chamberlain (American) for their work in demonstrating the existence of the antiproton.
1960 Donald A. Glaser (American) for inventing the bubble chamber to study subatomic particles.
1961 Robert Hofstadter (American) for his studies of nucleons, and *Rudolf L. Mössbauer (German) for his research on gamma rays.
1962 Lev Davidovich Landau (Soviet) for his research on liquid helium.
1963 *Eugene Paul Wigner (American) for his contributions to the understanding of atomic nuclei and the elementary particles, and *Maria Goeppert Mayer (American) and *J. Hans Jensen (German) for their work on the structure of atomic nuclei.
1964 Charles H. Townes (American) and *Nikolai G. Basov and *Alexander M. Prokhorov (Soviet) for developing masers and lasers.
1965 Sin-itiro Tomonaga (Japanese) and Julian S. Schwinger and *Richard P. Feynman (American) for basic work in quantum electrodynamics.
1966 Alfred Kastler (French) for his work on the energy levels of atoms.
1967 Hans Albrecht Bethe (American) for his contributions to the theory of nuclear reactions, especially his discoveries on the energy production in stars.
1968 Luis W. Alvarez (American) for his contributions to the knowledge of subatomic particles and their interactions.
1969 *Murray Gell-Mann (American) for his discoveries concerning the classification of nuclear particles and their interactions.
1970 *Hannes Olof Gösta Alfven (Swedish) for his work in magnetohydrodynamics, the study of electrical and magnetic effects in fluids that conduct electricity, and Louis Eugène Felix Noel (French) for his discoveries of magnetic properties that applied to computer memories.
1971 *Dennis Gabor (British) for his work in holography, a method of making a three-dimensional photograph with coherent light produced by a laser.
1972 *John Bardeen, Leon N. Cooper, and John Robert Schrieffer (American) for their work on superconductivity; the disappearance of electrical resistance.
1973 Ivar Giaever (American), Leo Esaki (Japanese), and Brian Josephson (British) for their work on the phenomena of electron 'tunneling' through semiconductor and superconductor materials.
1974 Antony Hewish (British) for his decisive role in the discovery of pulsars, and Sir Martin Ryle (British) for his use of small radio telescopes to 'see' into space with great accuracy.
1975 L. James Rainwater (American) and Aage N. Bohr and Ben R. Mottelson (Danish) for their work on the structure of the atomic nucleus.
1976 Burton Richter and Samuel Chao Chung Ting (American) for their discovery of an elementary nuclear particle called the psi or J. particle.
1977 Philip W. Anderson and John H. Van Vleck (American) and Sir Nevill F. Mott (British) for helping develop semiconductor devices.
1978 Pyotr Kapitsa (Soviet) for his research in low-temperature physics, and Arno Penzias and Robert Wilson (American) for their discovery and study of cosmic microwave background radiation.
1979 Sheldon L. Glashow and Steven Weinberg (American) and Abdus Salam (Pakistan) for developing a principle that unifies the weak nuclear force and the force of electromagnetism.
1980 James W. Cronin and Val L. Fitch (American) for their research on subatomic particles revealing that the fundamental laws of symmetry in nature could be violated.
1981 Nicolaas Bloembergen and Arthur L. Schawlow (American) for their contribution to the development of laser spectroscopy, and Kai Siegbahn (Swedish) for his contribution to the development of high-resolution electron spectroscopy.
1982 Kenneth G. Wilson (American) for his method of analyzing the behavior of matter when it changes form—for example, from water to steam.
1983 Subrahmanyan Chandrasekhar and William A. Fowler (American) for work on the evolution and death of stars.
1984 Carlo Rubbia (Italian) and Simon van der Meer (Dutch) for contributions to the discovery of two subatomic particles—the W particle and the Z particle.
1985 Klaus von Klitzing (West German) for developing a precise way of measuring electrical resistance.
1986 Ernst Ruska (West German) for his invention of the electron microscope and C. G. Binning (West German) and Heinrich Rohrer (Swiss) for their invention of the scanning tunneling microscope.
1987 J. Georg Bednorz (West German) and K. Alex Müller (Swiss) for their discovery of superconductivity in a ceramic material.
1988 Leon N. Lederman, Melvin Schwartz, and Jack Steinberger (American) for their work on subatomic particles called neutrinos.
1989 Hans G. Dehmelt (American) and Wolfgang Paul (German) for isolating and measuring single atoms, and Norman F. Ramsey (American) for work that led to the atomic clock.
Marie Curie shared the 1903 physics prize with her husband, Pierre, for their study of radiation and with Antoine Henri Becquerel for his discovery of natural radioactivity. Marie Curie also won the 1911 chemistry prize for her discovery of and work with the elements radium and polonium.

1900 Jerome Friedman and "Henry Kendall (American) and Richard Taylor (Canadian) for experiments that proved the existence of subatomic particles called quarks.

1901 Pierre-Gilles de Gennes (French) for his analyses of alignments and other orderly arrangements of molecules in certain substances.

1902 Georges Charpak (French) for the invention of devices that detect subatomic particles in particle accelerators.

Nobel Prizes in chemistry

1901 Jacobus Henricus Van't Hoff (Dutch) for discovering laws of chemical dynamics and osmotic pressure.

1902 Emil Fischer (German) for synthesizing sugars, purine derivatives, and peptides.

1903 Svante August Arrhenius (Swedish) for his dissociation theory of ionization in electrolytes.

1904 "Sir William Ramsay (British) for discovering helium, neon, xenon, and krypton, and determining their place in the periodic system.

1905 Adolph von Baeyer (German) for his work on dyes and organic compounds, and for synthesizing indigo and arsenicals.

1906 Henri Moissan (French) for preparing pure fluorine and developing the electric furnace.

1907 Eduard Buchner (German) for his biochemical researches and for discovering cell-less fermentation.

1908 Ernest Rutherford (New Zealand-born) for discovering that radioactive elements change into other elements.

1909 "Wilhelm Ostwald (German) for his work on catalysis, chemical equilibrium, and the rate of chemical reactions.

1910 Otto Wallach (German) for work on aliphatic substances.

1911 "Marie Curie (French) for discovering radium and polonium, isolating radium, and studying radium's compounds.

1912 François A. V. Grignard (French) for discovering the Grignard reagent to synthesize organic compounds, and Paul Sabatier (French) for his method of using nickel as a hydrogenation catalyst.

1913 Alfred Werner (Swiss) for his coordination theory on the arrangement of atoms.

1914 Theodore W. Richards (American) for determining the atomic weights of many elements.

1915 Richard Willstätter (German) for his research on chlorophyll and other coloring matter in plants.

1916-1917 No award

1918 Fritz Haber (German) for the Haber-Bosch process of synthesizing ammonia from nitrogen and hydrogen.

1919 No award

1920 Walther Nernst (German) for his discoveries concerning heat changes in chemical reactions.

1921 "Frederick Soddy (British) for studying radioactive substances and isotopes.

1922 Francis W. Aston (British) for finding many isotopes by means of the mass spectograph and for discovering the whole number rule on the structure and weight of atoms.

1923 Fritz Pregl (Austrian) for inventing a method of microanalyzing organic substances.

1924 No award

1925 Richard Zsigmondy (Austrian) for his method of studying colloids.

1926 Theodor Svedberg (Swedish) for his work on dispersions and on colloid chemistry.

1927 Heinrich O. Wieland (German) for studying gall acids and related substances.

1928 Adolf Windaus (German) for studying steroids and their connection with vitamins.

1929 Sir Arthur Harden (British) and Hans August Simon von Euler-Chelpin (German) for their research on sugar fermentation and enzymes.

1930 Hans Fischer (German) for studying the coloring matter of blood and leaves and synthesizing hemin.

1931 Carl Bosch and Friedrich Bergius (German) for inventing high-pressure methods of manufacturing ammonia and liquefying coal.

1932 Irving Langmuir (American) for his discoveries about molecular films absorbed on surfaces.

1933 No award

1934 "Harold Clayton Urey (American) for discovering deuterium (heavy hydrogen).

1935 Frédéric and "Irène Joliot-Curie (French) for synthesizing new radioactive elements.

1936 Peter J. W. Debye (Dutch) for his studies on dipole moments, the diffraction of electrons, and X rays in gases.

1937 Sir Walter N. Haworth (British) for his research on carbohydrates and vitamin C, and Paul Karrer (Swiss) for studying carotenoids, flavins, and vitamins A and B.

1938 Richard Kuhn (German) for his work on carotenoids and vitamins A.

*Has a biography in World Book.
obel Prizes in chemistry (continued)

1973 Geoffrey Wilkinson (British) and Ernst Fischer (German) for their work on organometallic compounds, which consist of organic compounds and metal atoms.

1974 Paul John Flory (American) for work in polymer chemistry.

1975 John Warcup Cornforth (Australian-born) and Vladimir Prelog (Swiss) for their work on the chemical synthesis of important organic compounds.

1976 William N. Lipscomb, Jr. (American), for his studies on the structure and bonding mechanisms of boranes, complex compounds of boron and hydrogen.

1977 Ilya Prigogine (Belgian) for his contributions to non-equilibrium thermodynamics.

1978 Peter Mitchell (British) for his studies of cellular energy transfer.

1979 Herbert C. Brown (American) and Georg Wittig (German) for developing compounds capable of producing chemical bonds useful in the manufacture of drugs and in other industrial processes.

1980 Paul Berg and Walter Gilbert (American) and *Frederick Sanger (British) for their studies of the chemical structure of nucleic acids.

1981 Kenichi Fukui (Japanese) and Roald Hoffmann (American) for applying the theories of quantum mechanics to predict the course of chemical reactions.

1982 Aaron Klug (British) for his work with the electron microscope and for his research into the structure of nucleic acid-protein complexes.

1983 Henry Taube (American) for his research on the transfer of electrons between molecules in chemical reactions.

1984 R. Bruce Merrifield (American) for developing a rapid, automated method for making peptides, the building blocks of proteins.

1985 Herbert A. Hauptman and Jerome Karle (American) for developing techniques for quickly determining the chemical structure of molecules vital to life.

1986 Dudley R. Herschbach and Yuan T. Lee (American) and John C. Polanyi (Canadian) for their pioneering research on basic chemical reactions.

1987 Jean-Marie Lehn (French) and Donald J. Cram and Charles J. Pedersen (American) for their development of, and work with, artificial molecules that function like natural organic molecules.

1988 Johann Deisenhofer, Robert Huber, and Hartmut Michel (West German) for revealing the structure of proteins that are essential to photosynthesis.

1989 Sidney Altman and Thomas R. Cech (American) for their discovery that ribonucleic acid (RNA) is able to assist chemical reactions in cells.

1990 Elias James Corey (American) for developing techniques for artificially duplicating such natural substances as compounds for use as drugs.

1991 Richard R. Ernst (Swiss) for improvements in the use of nuclear magnetic resonance (NMR) to analyze chemicals.

1992 Rudolph A. Marcus (American) for analyzing the transfer of electrons between molecules.

1993 Kary B. Mullis (American) for his method of copying genetic material, and Michael Smith (Canadian) for his method of altering DNA molecules.

1994 George A. Olah (Hungarian-born) for discovering ways to break up hydrocarbon molecules and stabilize the resulting parts.

1995 Mario Molina and F. Sherwood Rowland (American) and Paul Crutzen (Dutch) for work leading to the discovery of a "hole" in the earth’s protective layer of ozone.

1996 Richard E. Smalley and Robert F. Curl, Jr. (American), and Sir Harold W. Kroto (British) for discovering carbon molecules called fullerenes.

1997 Paul D. Boyer (American), Jens C. Skou (Danish), and John E. Walker (British) for discoveries about adenosine triphosphate (ATP), a molecule living things use to store energy.

1998 Walter Kohn (Austrian-born American) for his mathematical analysis of chemical bonds, and John A. Pople (British)

*Has a biography in World Book
1914
1909
1903
1902

1901
Emil von Behring (German) for discovering the diphtheria antitoxin.

1902
Sir Ronald Ross (British) for working on malaria and discovering how malaria is transmitted.

1903
Niels Ryberg Finsen (Danish) for treating diseases, especially lupus vulgaris, with concentrated light rays.

1904
Ivan Petrovich Pavlov (Russian) for his work on the physiology of digestion.

1905
Robert Koch (German) for working on tuberculosis and discovering the tubercle bacillus and tuberculin.

1906
Camillo Golgi (Italian) and Santiago Ramon y Cajal (Spanish) for their studies of nerve tissue.

1907
Charles Louis Alphonse Laveran (French) for studying diseases caused by protozoans.

1908
Paul Ehrlich (German) and *Elie Metchnikoff (Russian) for their work on immunity.

1909
Emil Theodor Kocher (Swiss) for his work on the physiology, pathology, and surgery of the thyroid gland.

1910
Albrecht Kossel (German) for studying cell chemistry, proteins, and nucleic substances.

1911
Allvar Gullstrand (Swedish) for his work on dioptrics, the refraction of light through the eye.

1912
Alexis Carrel (French) for suturing blood vessels and grafting vessels and organs.

1913
Charles Robert Richet (French) for studying allergies caused by foreign substances, as in hay fever.

1914
Robert Bárány (Austrian) for work on function and diseases of equal and inner ear organs.

1915-1918
No award

1919
Jules Bordet (Belgian) for discoveries on immunity.

1920
August Krogh (Danish) for discovering the system of action of blood capillaries.

1921
No award

1922
Archibald V. Hill (British) for his discovery on heat production in the muscles, and Otto Meyerhof (German) for his theory on the production of lactic acid in the muscles.

1923
Sir Frederick G. Banting (Canadian) and John J. R. Macleod (Scottish) for discovering insulin.

1924
Willem Einthoven (Dutch) for his discovery of the way in which electrocardiography works.

1925
No award

1926
Johannes Fibiger (Danish) for discovering a parasite that causes cancer.

*Has a biography in World Book.

Ivan Petrovich Pavlov, a Russian physiologist, won the 1904 prize in physiology or medicine. Pavlov and his staff experimented with dogs to learn how nerves affect the process of digestion.

Nobel Prizes in chemistry (continued)

for his computer techniques for determining the structure of molecules.

1999
Ahmed H. Zewail (Egyptian-born American) for his development of experimental techniques for detecting the individual steps of chemical reactions.

2000
Alan J. Heeger (American), Alan G. MacDiarmid (New Zealand-born American), and Hideki Shirakawa (Japanese) for the discovery and development of polymers that can conduct electric current.

2001
William S. Knowles (American), Ryoji Noyori (Japanese), and K. Barry Sharpless (American) for their development of molecules that are used to produce a number of drugs.

2012
Julius Wagner von Jauregg (Austrian) for discovering the fever treatment for paralysis.

1928
Charles Nicolle (French) for his work on typhus.

1929
Christian Eijkman (Dutch) for discovering vitamins that prevent beriberi, and Sir Frederick Hopkins (British) for finding vitamins that aid growth.

1930
Karl Landsteiner (American) for discovering the four main human blood types.

1931
Otto H. Warburg (German) for discovering that enzymes aid in respiration by tissues.

1932
Edgar D. Adrian and Sir Charles S. Sherrington (British) for their discoveries on the function of neurons.

1933
Thomas H. Morgan (American) for studying the function of chromosomes in heredity.

1934
George R. Minot, William P. Murphy, and George H. Whipple (American) for their discoveries on liver treatment for anemia.

1935
Hans Spleman (German) for discovering the organizer effect in the growth of an embryo.

1936
Sir Henry H. Dale (British) and Otto Loewi (German-born) for their discoveries on the chemical transmission of nerve impulses.

1937
Albert Szent-Györgyi (Hungarian) for his discoveries in connection with oxidation in tissues, vitamin C, and fumaric acid.

1938
Cornelie Heymans (Belgian) for her discoveries concerning the regulation of respiration.

1939
Gerhard Domagk (German) for discovering Prontosil, the first sulfa drug (declined).

1940-1942
No award

1943
Henrik Dam (Danish) for discovering vitamin K, and Edward Doisy (American) for synthesizing it.

1944
Joseph Erlanger and Herbert Gasser (American) for their work on single nerve fibers.

1945
Alexander Fleming (British) for discovering penicillin, and Howard W. Florey and Ernst B. Chain (British) for developing its use as an antibiotic.

1946
Hermann Joseph Muller (American) for discovering that X rays can produce mutations.

1947
Carl F. and Gerty Cori (American) for their work on insulin and Bernardo Houssay (Argentine) for studying the pancreas and the pituitary gland.

1948
Paul H. Müller (Swiss) for discovering the insect-killing properties of DDT.

1949
Walter R. Hess (Swiss) for discovering how certain parts of the brain control organs of the body, and António Egas Moniz (Portuguese) for originating prefrontal lobotomy.

1950
Philip S. Hinch, Edward C. Kendall (American), and Tadeo Reichstein (Swiss) for discoveries on cortisone and ACTH.

1951
Max Theiler (South African who worked in the United States) for developing the yellow fever vaccine 17-D.

1952
Selman A. Waksman (American) for his work in the discovery of streptomycin.

1953
Fritz Albert Lipmann (American) and "Hans Adolf Krebs (British) for discoveries in biosynthesis and metabolism.

1954
John F. Enders, Thomas H. Weller, and Frederick C. Robbins (American) for discovering a simple method of growing polio virus in test tubes.

1955
Hugo Theorell (Swedish) for his discoveries on the nature and action of oxidation enzymes.

1956
André F. Courmand, Dickinson W. Richards (American), and Werner Forssmann (German) for using a catheter to chart the interior of the heart.

1957
Daniel Bovet (Italian) for discovering antihistamines.
Nobel Prizes in physiology or medicine (continued)

1958 *George Wells Beadle and Edward Lawrie Tatum (American) for their work in biochemical genetics, and *Joshua Lederberg (American) for his studies of genetics in bacteria.

1959 Severo Ochoa and Arthur Kornberg (American) for producing nucleic acid by artificial means.

1960 *Sir Macfarlane Burnet (Australian) and Peter B. Medawar (British) for research in transplanting human organs.

1961 *Georg von Békésy (American) for demonstrating how the ear distinguishes among various sounds.

1962 *James D. Watson (American) and *Francis H. C. Crick, and *Maurice H. F. Wilkins (British) for work on nucleic acid.

1963 *Sir John Carew Eccles (Australian) for his research on the transmission of nerve impulses, and Alan Lloyd Hodgkin (British) and Andrew Fielding Huxley (British) for their discoveries concerning the electrical activity of nerve fibers.

1964 *Konrad E. Bloch (American) and *Feodor Lynen (German) for their work on cholesterol and fatty acid metabolism.

1965 François Jacob, André Lwoff, and Jacques Monod (French) for their discoveries concerning genetic control of enzyme and virus synthesis.

1966 *Francis Peyton Rous (American) for discovering a cancer-producing virus, and Charles H. Best (Canadian) for discovering uses of hormones in treating cancer.

1967 Ragnar Granit (Swedish) and H. Kuffer Hartline and *George Wald (American) for their findings about chemical and physiological processes that take place in the eye.

1969 Max Delbrück, Alfred Hershey, and Salvador Luria (American) for their work with bacteriophages (viruses that attack bacteria).

1970 Julius Axelrod (American), Bernard Katz (British), and Ulf Svante von Euler (Swedish) for their discoveries of the role played by certain chemicals in the transmission of nerve impulses.

1971 Earl W. Sutherland, Jr. (American), for his discovery of the ways hormones act, including the discovery of cyclic AMP, a chemical that influences the actions of hormones on body processes.

1972 Gerald M. Edelman (American) and Rodney R. Porter (British) for their discovery of the chemical structure of antibodies.

1973 *Nikolaas Tinbergen (Dutch-born) and *Konrad Z. Lorenz and *Karl von Frisch (Austrian) for their studies on animal behavior.

1974 Christian de Duve (Belgian) and Albert Claude and George E. Palade (American) for their pioneer work in cell biology.

1975 David Baltimore, Renato Dulbecco, and Howard M. Temin (American) for their research on how certain viruses affect the genes of cancer cells.

1976 Baruch S. Blumberg and D. Carleton Gajdusek (American) for their discoveries concerning the origin and spread of infectious diseases.

1977 Roger Guillemin, Andrew Schally, and Rosalyn Yalow (American) for their research concerning the role of hormones in the chemistry of the body.

1978 Werner Arber (Swiss) and Daniel Nathans and Hamilton O. Smith (American) for discoveries in molecular genetics.

1979 Allan MacLeod Cormack (American) and Godfrey N. Hounsfield (British) for their contributions to development of the computerized tomographic (CT) scanner.

Nobel Prizes in literature

1901 *Sully Prudhomme (French) for his poems.

1902 Theodor Mommsen (German) for his historical narratives, particularly his history of Rome.

1903 *Bjørnstjerne Bjørnson (Norwegian) for his novels, poems, and dramas.

1904 *Frédéric Mistral (French) for his poems, and José Echegaray y Eizaguirre (Spanish) for his dramas.

1905 *Henrik Sienkiewicz (Polish) for his novels.

1906 *Giosuè Carducci (Italian) for his poems.

1907 *Rudyard Kipling (British) for his stories, novels, and poems.

1908 Rudolf Eucken (German) for his philosophic writings.

1909 *Selma Lagerlöf (Swedish) for her novels and poems.

*Has a biography in *World Book.

---

1980 Baruj Benacerraf and George D. Snell (American) and Jean Dausset (French) for their discoveries concerning the genetic regulation of the body's immune system.

1981 Roger W. Sperry and David H. Hubel (American) and Torsten N. Wiesel (Swedish) for their research on the organization and functioning of the brain.

1982 Sune K. Bergstrom and Bengt I. Samuelsson (Swedish) and John R. Vane (British) for their discoveries regarding prostaglandins and related substances.

1983 *Barbara McClintock (American) for her discovery that genes sometimes behave unexpectedly inside cells.

1984 Niels K. Jerne (British-born), Georges J. F. Köhler (German), and Cesar Milstein (Argentine) for their discoveries in immunology.

1985 Michael S. Brown and Joseph L. Goldstein (American) for explaining how high cholesterol causes heart disease.

1986 Stanley Cohen (American) and Rita Levi-Montalcini (Italian-born) for their research on cell and organ growth.

1987 Susumu Tonegawa (Japanese) for his discoveries on how genes change to produce antibodies against specific disease agents.

1988 *Gertrude B. Elion and George H. Hitchings (American) and Sir James Black (British) for their discoveries of important principles for drug treatment.

1989 J. Michael Bishop and Harold E. Varmus (American) for their research on cancer-causing genes called *oncopogenes.

1990 Joseph E. Murray and E. Donnell Thomas (American) for their work in transplanting human organs and bone marrow.

1991 Erwin Neher and Bert Sakmann (German) for discovering how cells communicate with one another.

1992 Edmond Fischer and Edwin Krebs (American) for discovering a chemical process in cells that is linked to cancer and to rejection of transplanted organs.

1993 Richard J. Roberts (British-born) and Phillip A. Sharp (American) for their discoveries regarding the structure and function of genes.

1994 Alfred G. Gilman and Martin Rodbell (American) for their research into signaling mechanisms in cells.

1995 Edward B. Lewis and Eric Wieschaus (American) and Christiane Nüsslein-Volhard (German) for their studies of how genes control early embryo development.

1996 Peter C. Doherty (Australian) and Rolf M. Zinkernagel (Swiss) for discovering the signals that alert white blood cells to kill virus-infected cells.

1997 Stanley B. Prusiner (American) for his discovery of prions, a new type of infectious particle that appears to consist only of protein.

1998 Robert F. Furchgott, Louis J. Ignarro, and Ferid Murad (American) for their discovery that the gas nitric oxide acts as an important signal molecule in the heart and blood vessels.

1999 Günter Blobel (German-born) for his discoveries on the movement of proteins within the cells of living organisms.

2000 Arvid Carlsson (Swedish) and Paul Greengard and Eric Kandel (American) for their research on the transmission of impulses between nerve cells.

2001 Leland H. Hartwell (American) and Timothy Hunt and Sir Paul Nurse (British) for their discoveries regarding genetic control of cell division in living organisms.
1910 Paul von Heyse (German) for his poems, novels, and dramas.
1911 Maurice Maeterlinck (Belgian) for his dramas.
1912 Gerhart Hauptmann (German) for his dramas.
1913 Rabindranath Tagore (Indian) for his poems.
1914 No award
1915 Romain Rolland (French) for his novels.
1916 Verner von Heidenstam (Swedish) for his poems.
1917 Karl Gjellerup (Danish) for his poems and novels, and Henrik Pontoppidan (Danish) for his novels and short stories.
1918 No award
1919 Carl Spitteler (Swiss) for his epics, stories, and essays.
1920 Knut Hamsun (Norwegian) for his novels.
1921 Anatole France (French) for his novels, short stories, and essays.
1922 Jacinto Benavente (Spanish) for his dramas.
1923 William Butler Yeats (Irish) for his poems.
1924 Władysław S. Reymont (Polish) for his novels.
1925 George Bernard Shaw (Irish-born) for his plays.
1926 Grazia Deledda (Italian) for her novels.
1927 Henri Bergson (French) for his philosophic writings.
1928 Sigrid Undset (Norwegian) for her novels.
1929 Thomas Mann (German) principally for his novel Buddenbrooks.
1930 Sinclair Lewis (American) for his novels.
1931 Erik Axel Karlfeldt (Swedish) for his lyric poetry.
1932 John Galsworthy (British) for his novels, plays, and short stories.
1933 Ivan Bunin (Soviet) for his novels, short stories, and poems.
1934 Luigi Pirandello (Italian) for his dramas.
1935 No award
1936 Eugene O'Neill (American) for his dramas.
1937 Roger Martin du Gard (French) for his novels.
1938 Pearl S. Buck (American) for her novels.
1939 Frans Eemil Sillanpää (Finnish) for his novels.
1940-1943 No award
1944 Johannes V. Jensen (Danish) for his poems and novels.
1945 Gabriela Mistral (Chilean) for her poems.
1946 Hermann Hesse (German) for his novels, poems, and essays.
1947 André Gide (French) for his novels.
1948 T. S. Eliot (British) for his poems, essays, and plays.
1949 William Faulkner (American) for his novels. (Award delayed until 1950.)

*His a biography in World Book.

Sinclair Lewis became the first American to win the literature prize. He received the award in 1930 for his satirical novels.

United Press Int.
Nobel Peace Prizes

1901 *Jean Henri Dunant (Swiss) for founding the Red Cross and originating the Geneva Convention, and Frederic Passy (French) for his activities as founder and secretary of the International Arbitration League.

1902 Elle Ducommun (Swiss) for his work as honorary secretary of the International Peace Bureau, and Charles Albert Gobat (Swiss) for his work as administrator of the Inter-Parliamentary Union.

1903 Sir William Cremer (British) for his activities as founder and secretary of the International Arbitration League.

1904 The Institute of International Law for its studies on the laws of neutrality and other phases of international law.

1905 Baroness Bertha von Suttner (Austrian) for promoting pacifism and founding an Austrian peace society.

1906 *Theodore Roosevelt (American) for negotiating peace in the Russo-Japanese War.

1907 Ernesto T. Moneta (Italian) for his work as president of the Lombard League for Peace, and Louis Renault (French) for organizing international conferences and representing France at two peace conferences.

1908 Klas Pontus Arnoldson (Swedish) for founding the Swedish Society for Arbitration and Peace, and Fredrik Bajer (Danish) for his work on the International Peace Bureau.

1909 Auguste M. F. Beermaert (Belgian) for his work on the Permanent Court of Arbitration, and Paul d'Estournelles (French) for founding and directing the French Parliamentary Arbitration Committee and League of International Conciliation.

1910 The International Peace Bureau for promoting international arbitration and organizing peace conferences.

1911 Tobias M. C. Asser (Dutch) for organizing conferences on international law, and Alfred H. Fried (Austrian) for his writings on peace as editor of Die Friedenswarte.

1912 *Elihu Root (American) for settling the problem of Japanese immigration to California and organizing the Central American Peace Conference.

1913 Henri Lafontaine (Belgian) for his work as president of the International Peace Bureau.

1914-1916 No award

1917 The International Red Cross for doing relief work during World War I.

1918 No award

1919 *Woodrow Wilson (American) for attempting a just settlement of World War I and advocating the League of Nations. (Award delayed until 1920.)

1920 Léon Bourgeois (French) for his contribution as president of the Council of the League of Nations.

1921 Karl Hjalmar Branting (Swedish) for promoting social reforms in Sweden and serving as the Swedish delegate to the League of Nations, and Christian Louis Lange (Norwegian) for his contribution as secretary-general of the Inter-Parliamentary Union.

1922 *Fridtjof Nansen (Norwegian) for doing relief work among Russian prisoners of war and in famine areas in Russia.

1923-1924 No award

1925 Sir Austen Chamberlain (British) for helping work out the Locarno Peace Pact, and *Charles G. Dawes (American) for originating a plan for payment of German reparations.

1926 *Aristide Briand (French) for his part in forming the Locarno Peace Pact, and Gustav Stresemann (German) for persuading Germany to accept plans for reparations.

1927 Ferdinand Buisson (French) for his contribution as president of the League of Human Rights, and Ludwig Quiddle (German) for his writings on peace and his work in international peace congresses.

1928 No award

1929 Frank Billings Kellogg (American) for negotiating the Kellogg-Briand Peace Pact.

1930 Nathan Söderblom (Swedish) for writing on and working for peace.

1931 *Jane Addams (American) for her work with the Women’s International League for Peace and Freedom, and *Nicholas M. Butler (American) for his work with the Carnegie Endowment for International Peace.

1932 No award

1933 Sir Norman Angell (British) for his work with the Royal Institute of International Affairs, the League of Nations, and the National Peace Council.

1934 *Arthur Henderson (British) for his contribution as president of the World Disarmament Conference.

1935 Carl von Ossietzky (German) for promoting world disarmament. (Award delayed until 1936.)

1936 Carlos Saavedra Lamas (Argentine) for negotiating a peace settlement between Bolivia and Paraguay in the Chaco War.

1937 Edgar Algernon Robert Gascoyne Cecil (British) for promoting the League of Nations and working with peace movements.

1938 The Nansen International Office for Refugees for directing relief work among refugees.

1939-1943 No award

1944 The International Red Cross for doing relief work during World War II.

1945 *Cordell Hull (American) for his peace efforts as secretary of state.

1946 John R. Mott (American) for his YMCA work and for aiding displaced persons, and *Emily Greene Balch (American) for her work with the Women’s International League for Peace and Freedom.

1947 The Friends Service Council and the American Friends Service Committee for humanitarian work.

1948 No award

1949 John Boyd Orr (British) for directing the United Nations Food and Agriculture Organization.

1950 *Ralph J. Bunche (American) for his work as UN mediator in Palestine in 1948 and 1949.

1951 Léon Jouhaux (French) for his work helping to organize national and international labor unions.

*Has a biography in World Book

Elihu Root won the Nobel Peace Prize in 1912. As U.S. secretary of state, Root made important contributions to world peace.

Woodrow Wilson won the 1919 peace prize, the second awarded to a U.S. president. Theodore Roosevelt won in 1906.
Jane Addams, an American social worker, shared the 1931 peace prize for her work with an international peace group.

Nobel Peace Prizes (continued)

1952 *Albert Schweitzer (German-born) for his humanitarian work in Africa. (Award delayed until 1953.)

1953 *George C. Marshall (American) for promoting peace through the European Recovery Program.

1955-1956 No award

1957 *Lester B. Pearson (Canadian) for organizing a United Nations force in Egypt.

1958 Dominique Geay (French) for his work in resettling displaced persons.

1959 Philip Noel-Baker (British) for his work in promoting peace and disarmament.

1960 *Albert John Luthuli (African) for his peaceful campaign against racial restrictions in South Africa.

1961 * Dag Hammarskjöld (Swedish) for his efforts to bring peace to the Congo (awarded posthumously).

1962 *Linus Pauling (American) for efforts to ban nuclear weapons and nuclear testing.

1963 International Committee of the Red Cross and League of Red Cross Societies for humanitarian work.

1964 *Martin Luther King, Jr. (American) for leading the black struggle for equality in the United States through nonviolent means.

1966-1967 No award

1968 René Cassin (French) for promoting human rights.

Albert Schweitzer won the 1952 Nobel Peace Prize. He devoted most of his life to humanitarian work in Africa.

1969 *International Labour Organization (ILO) for its efforts to improve working conditions.

1970 *Norman E. Borlaug (American) for his role in developing high-yield grains that increased food production in developing countries.

1971 *Willy Brandt (German) for his efforts to improve relations between Communist and non-Communist nations.

1972 No award

1973 *Henry Kissinger (American) and Le Duc Tho (North Vietnamese) for their work in negotiating the Vietnam War cease-fire agreement (Le Duc Tho declined).

1974 Sean MacBride (Irish) for working to guarantee human rights through international law, and Eisaku Sato (Japanese) for his efforts to improve international relations and stop the spread of nuclear weapons.

1975 Andrei D. Sakharov (Soviet) for his work in promoting peace and opposing violence and brutality.

1976 Mairead Corrigan and Betty Williams (Irish) for organizing a movement to end Protestant-Catholic fighting in Northern Ireland. (Award delayed until 1977.)

1977 Amnesty International for helping political prisoners.

1978 Menachem Begin (Israel) and Anwar el-Sadat (Egyptian) for their efforts to bring about a settlement of the Arab-Israeli conflict.

1979 *Mother Teresa (Indian) for aiding India's poor.

1980 Adolfo Pérez Esquivel (Argentine) for his role in Service

*Has a biography in World Book.

Lester B. Pearson was the first Canadian to win the peace prize. He won the 1957 award for his work in the United Nations.

Martin Luther King, Jr., won the 1964 peace prize for leading nonviolent civil rights demonstrations in the United States.
for Peace and Justice in Latin America, a group promoting the cause of human rights.

1982 *Alva Myrdal (Swedish) and Alfonso García Robles (Mexican) for their contributions to United Nations disarmament negotiations.

1983 *Lech Wałęsa (Polish) for his efforts to prevent violence while trying to gain workers' rights.

1984 *Desmond Tutu (South African) for leading a nonviolent campaign against racial segregation in his country.

1985 *International Physicians for the Prevention of Nuclear War for educating the public on the effects of nuclear war.

1986 *Elie Wiesel (American) for his vigorous efforts to help victims of oppression and racial discrimination.

1987 *Óscar Arias Sánchez (Costa Rican) for authoring a plan to end civil wars in Central America.

1988 The United Nations peacekeeping forces for helping control military conflict in the Middle East and other areas.

1989 *The Dalai Lama (Tibetan) for his nonviolent struggle to end China's rule of Tibet.

1990 *Mikhail S. Gorbachev (Soviet) for his efforts to promote world peace, including his role in reducing tensions between Communist and non-Communist countries.

1991 *Aung San Suu Kyi (Burmeese) for her nonviolent struggle for democracy and human rights in Myanmar.

1992 *Rigoberta Menchú (Guatemalan) for her work to gain respect for the rights of Guatemala's Indian peoples.

1993 *Nelson Mandela and *Frederick W. de Klerk (South African) for working to end apartheid in South Africa and to enable its nonwhites to fully participate in government.

1994 *Yasir Arafat (Palestinian), *Shimon Peres (Israeli), and *Yitzhak Rabin (Israeli) for their efforts to create peace in the Middle East.

1995 The organization known as the Pugwash Conferences on Science and World Affairs and its president, *Joseph Rotblat (British), for their efforts to eliminate nuclear weapons.

1996 *Carlos Ximenes Belo (Timorese) and *José Ramos-Horta (Timorese) for work on behalf of the people of East Timor.

1997 International Campaign to Ban Landmines and its coordinator, *Jody Williams (American), for their work to end the use of land mines worldwide.

1998 *John Hume (British) and *David Trimble (British) for working to end Protestant-Catholic fighting in Northern Ireland.

1999 *Doctors Without Borders (French) for its pioneering work in providing medical care and humanitarian aid to victims of disasters on several continents.

2000 *Kim Dae Jung (South Korean) for his efforts to end hostility between North Korea and South Korea.

2001 *Kofi Annan (*Ghanaian) and the United Nations for their efforts to build peace and security throughout the world.

**Bank of Sweden Prizes in Economic Sciences in Memory of Alfred Nobel**

1969 *Ragnar Frisch (Norwegian) and *Jan Tinbergen (Dutch) for their work in *econometrics, a method of analyzing economic activity.

1970 *Paul A. Samuelson (American) for raising the level of scientific analysis in economic theory.

1971 *Simon Kuznets (American) for his interpretation of economic growth.

1972 *Kenneth J. Arrow (American) and Sir John Hicks (British) for their pioneering contribution to general equilibrium theory and to welfare theory.

1973 Wassily Leontief (American) for his development of the input-output method of economic analysis.

1974 *Friedrich von Hayek (Austrian) and *Gunnar Myrdal (Swedish) for their work in the theory of money and economic change and in the relationship between economic and social factors.

1975 Leonid V. Kantorovich (Soviet) and Tjalling C. Koopmans (American) for their work on how economic resources should be distributed and used.

1976 *Milton Friedman (American) for his work in the fields of economic consumption, monetary history and theory, and price stabilization policy.

1977 *James Meade (British) and Bertil Ohlin (Swedish) for their studies of international trade and finance.

1978 *Herbert A. Simon (American) for his research on the decision-making process in business.

1979 *Sir Arthur Lewis (St. Lucian-born) and Theodore W. Schultz (American) for their research into the economic problems of developing countries.

1980 *Lawrence R. Klein (American) for using econometric models to analyze economic policies and the rise and fall in business activity.

1981 James Tobin (American) for his analyses of financial markets and their effect on how businesses and families spend and save money.

1982 George Stigler (American) for his research on industrial organization, markets, and regulation.

1983 Gerard Debreu (American) for developing a mathematical model that proved the theory of supply and demand.

1984 *Richard Stone (British) for developing methods of measuring the performance of national economies.

1985 *Franco Modigliani (American) for his theories on personal savings and financial markets.

1986 *James M. Buchanan (American) for developing methods of analyzing the decision-making process in government.

1987 *Robert Solow (American) for his development of a mathematical model that identified technology as the dominant factor in long-term economic growth.

1988 Maurice Allais (French) for his theories on economic markets and the efficient use of resources.

1989 Trygve Haavelmo (Norwegian) for his development of statistical techniques that led to the creation of mathematical models used in making economic predictions.

1991 *Ronald H. Coase (British-Australian) for his theories on the economic importance of property rights and of the costs of carrying out business transactions.

1992 *Gary S. Becker (American) for extending economic theory to aspects of behavior that previously had been dealt with only by such fields as sociology and criminology.

1993 *Robert W. Fogel and *Douglass C. North (American) for their work in economic history.

1994 *John F. Nash (American), *John C. Harsanyi (American), and *Reinhard Selten (German) for their work in game theory.

1995 *Robert E. Lucas, Jr. (American) for his analysis of the impact of government economic policies on the economic decisions of individuals.

1996 *William S. Vickrey (American) and *James A. Mirrlees (British) for their contributions to the economic theory of incentives.

1998 *Amartya Sen (Indian) for his studies of such problems as famine and poverty from an ethical point of view.

1999 *Robert A. Mundell (Canadian-born) for his theories on how international factors affect governments' efforts to stabilize their economies.

2000 *James Heckman and *Daniel McFadden (American) for their work in the statistical analysis of the economic behavior of individuals and households.

2001 *George A. Akerlof, *Michael Spence, and *Joseph E. Stiglitz (American) for their research on how buyers and sellers with different amounts of information affect market systems.
Nobelium is an artificially produced radioactive element. It has an atomic number (number of protons) of 102. Its chemical symbol is No. Scientists have discovered 11 isotopes of nobelium, forms of the element with the same number of protons but different numbers of neutrons. These isotopes have atomic mass numbers (total numbers of protons and neutrons) from 250 to 260. The most stable isotope has a mass number of 259 and a half-life of 58 minutes—that is, due to radioactive decay, only half the atoms in a sample of isotope 259 would still be atoms of that isotope after 58 minutes.

In 1957, scientists at the Nobel Institute for Physics in Stockholm, Sweden, claimed that they had produced an element whose atomic number was 102. They proposed to name the element nobelium in honor of Swedish inventor Alfred Nobel. However, no other laboratory could confirm their claim.

In 1958, scientists at Lawrence Radiation Laboratory (now Lawrence Berkeley National Laboratory) in Berkeley, California, published the first in a series of claims that they had created element 102. In addition, the Berkeley scientists proposed the name nobelium. The International Union of Pure and Applied Chemistry (IUPAC) accepted this name. The IUPAC is the recognized authority in crediting the discovery of elements and naming them.

In the 1950s and 1960s, the Joint Institute for Nuclear Research (JINR) in Dubna, Russia, near Moscow, claimed that its scientists had discovered element 102. In 1986, the IUPAC and the International Union of Pure and Applied Physics formed a working group to review the histories of the elements with atomic numbers from 101 to 109. In 1993, the IUPAC accepted the working group's conclusion that the discovery of element 102 was first proved in 1966 at the JINR. The JINR scientists had bombarded americium, whose atomic number is 95, with nitrogen, whose atomic number is 7. Richard L. Hahn

**Nobility** is a class of people who are considered to stand at the top of their society. They have special political and social status. Nobility is inherited, and it carries titles such as duke or earl. Some nobles are the descendants of lords of the Middle Ages and have inherited their property as well as their titles. Others trace their ancestry to a person who was awarded a title for service to a modern monarch.

**In the United Kingdom**

The British nobility is called the peerage, and noblemen are known as peers. There are five grades of peers. From the highest to the lowest, they are: (1) duke; (2) marquess, or marquis; (3) earl; (4) viscount; and (5) baron. The wives of noblemen, and women who hold titles in their own right, are called peeresses. The five grades of peeresses are: (1) duchess, (2) marchioness, (3) countess, (4) viscountess, and (5) baroness.

The title of earl is the oldest grade of peer. It dates back to the Danish nobles who ruled much of England from the 800s to the 1000s. The rank of baron was introduced by the Normans when they conquered England in 1066. King Edward III of England created the rank of duke in 1337, when he named his oldest son as Duke of Cornwall. The title of marquess was added to the peerage in 1385, and the first viscount was introduced in 1440.

**The creation of peerages.** The British monarch now grants peerages on the recommendation of the prime minister. The monarch issues documents called letters patent, which create the peerage and specify how it will be inherited. In most cases, a peer's title passes to his eldest son. If he has no son, it usually goes to his closest male relative. The other children are commoners. The title becomes extinct if there is no male heir.

Some medieval peerages were created by royal orders called writs of summons. These types of peerages may pass to a daughter if the holder leaves no male descendant. If the daughter then has a son, he usually inherits the title.

Today, the British monarch rarely grants hereditary peerages. Each year, however, the monarch may grant titles called life peerages to distinguished persons. A life peerage involves the same privileges as a hereditary peerage, but it does not descend to the holder's children. Life peerages may be awarded to both men and women, and the title given is baron or baroness. Today, there are about 1,300 peers, including about 750 hereditary peers and about 600 life peers.

**Privileges of the peerage.** Until 1999, all peers who were at least 21 years old—except peers of Ireland and individuals who had been declared bankrupt or insane—were summoned to the House of Lords. The House of Lords is the upper house of the British Parliament. In 1999, reforms began that limited the number of hereditary peers sitting in the House of Lords to about 90. Life peers continued to serve as members of the Lords.

Peers are summoned because of the feudal agreement that lords and vassals should consult on important business. Women who are peeresses in their own right may also serve in the House of Lords. Peers who are serving in the House of Lords may not also serve in the lower house of Parliament—the House of Commons—and they cannot vote in parliamentary elections. Until 1948, peers accused of a felony or of treason had the right to be tried in the House of Lords by their fellow peers.

Dukes, marquesses, and earls have lesser titles besides the one by which they are known. Traditionally, the oldest son of one of these peers uses the highest of his father's lesser titles as a courtesy title. For example, the oldest son of the Duke of St. Albans uses the courtesy title Earl of Burford, but he is not a peer. A younger son of a duke adds Lord to his name, as in Lord Peter Grey. His sister would be Lady Helen Grey.

**In other countries**

In most other countries, titles of nobility have been officially abolished. A person who inherits a title may use it as part of his or her name. But the individual has none of the privileges of the former nobility. Titles of nobility were abolished in France in 1871, in Russia in 1917, in Germany in 1918, and in Japan—except those of the imperial family—in 1946. The titles were often abolished as part of a revolution or a major social and political effort to modernize the country.

The Constitution of the United States forbids the government to give anyone a title of nobility. The Constitution also prohibits federal officials from accepting any title from a foreign country without the special consent of Congress. Joel T. Rosenthal
Related articles in World Book include: Countess of the Realm Duke Lord Viscount

Noble gas refers to any of a group of six chemical elements. These elements are argon (Ar), helium (He), krypton (Kr), neon (Ne), radon (Rn), and xenon (Xe). They occur naturally and can be found in the atmosphere. The British scientists Lord Rayleigh and William Ramsay discovered the noble gases during the late 1890s.

Unlike most gaseous elements, the noble gases are monatomic—that is, they occur as single atoms instead of as molecules of two or more atoms. The atoms have stable configurations (arrangements) of electrons. Therefore, the atoms do not, under normal conditions, gain or lose electrons or share electrons with other elements. The six gases are called “noble gases” or inert gases because they do not readily react with other elements. But krypton, radon, and xenon do combine with fluorine and oxygen to form compounds.

The noble gases have various uses. Except for radon, which is highly radioactive, all of them are used as light sources in incandescent and gaseous-discharge lamps (see Electric light!). Some also are used in devices called gas lasers (see Laser [kinds of lasers]).

Argon and helium are used in a welding process called arc welding. They provide a chemically inactive atmosphere in which certain metals, such as aluminum, can be heated to their melting points without reacting chemically. Helium also is used in balloons that carry scientific instruments high into the atmosphere, and in low-temperature research. Each noble gas has a separate article in World Book.

Noguchi, Isamu (1904-1988), was an American sculptor whose work represents a wide variety of styles. Noguchi said that he was “suspicous of the whole business of style.” He called style “a form of inhibition.”

Noguchi worked in nearly every sculptural material. Almost all his work has no recognizable subject matter. Noguchi sought to preserve the nature of the sculptural material. He was intrigued by problems of weight, mass, and tension, which he used as themes.

Noguchi was born on Nov. 17, 1904, in Los Angeles. His mother was an American, and his father was a well-known Japanese poet and scholar. Noguchi lived in Japan from the age of 2 until he was 13. He gave up medical studies at Columbia University to return to sculpture, his earlier ambition. In the late 1920s, he studied in Paris with the Romanian-born sculptor Constantin Brancusi, who strongly influenced his work. Noguchi designed furniture and settings for ballets. He also collaborated with architects in planning gardens, playgrounds, and bridges. He died on Dec. 30, 1988.

George Gurney

Noise is random or unwanted sound. Unwanted signals, such as static that interferes with radio transmission, are also referred to as noise. The sound we hear is caused by vibrations of air molecules. A tuning fork produces an almost pure tone, with only one frequency, or rate of vibration (see Tone). Musical instruments produce harmonic sound. Such sound contains many frequencies, called overtones, that are harmonically related (see Harmonics). Random sound has many overtones that are not harmonically related.

Unwanted sound can be caused by any kind of sound—tones, harmonic sound, or random sound. Sound is unwanted if it is annoying or distracting, or if it damages the hearing mechanism. (Thomas A. Griffy)

Nok, Nah, was a West African civilization that flourished from about 300 B.C. until around A.D. 200. Archaeologists became aware of Nok in the 1940s, when small clay statues were discovered along the Jos Plateau in central Nigeria. These statues are the oldest sculptures ever found in Africa south of the Sahara. Bernard Fagg, a British archaeologist, studied these sculptures and other objects to learn about Nok’s people and culture. Fagg determined that Nok was spread along an area between the Niger and Benue rivers, southwest of the Jos Plateau. He named the culture Nok after the modern-day Nigerian village of Nok, where the statues were discovered.

The Nok sculptures are human and animal figures made of terra cotta (baked clay). Most stand no more than a foot (30 centimeters) high, but some are nearly life-sized. Distinctive features of Nok sculpture include a semicircular or triangular shape of the eyes. Most figures are hollow, with holes in the pupils, ears, noses, and mouths. Scholars are unsure what function the sculptures served. The figures may have been placed above the front doors of houses or displayed on altars.

Nok’s people were among the earliest ironworkers in Africa. They used low, circular iron-smelting furnaces. They also worked with some stone tools, particularly polished stone axes.

Little is known about the details of Nok society. Ar-

Isamu Noguchi’s sculptures typically portray abstract forms in arrangements of smooth, highly polished stone.

Nomad is a person who moves from one place to another to make a living. The word nomad comes from a Greek word that means one who wanders for pasture. Most nomadic peoples move through a certain area according to a cycle based on their activities and the seasons. Nomads traditionally travel by animal or canoe or on foot. Today, however, some nomads travel by motor vehicle. Most live in tents or other portable shelters.

Nomads keep moving for different reasons. For example, hunting and gathering nomads move in search of game, edible vegetation, and water. The African Pygmies, Australian Aborigines, and Negritos of Southeast Asia camp in different places to hunt animals and gather wild plants. Some American Indians followed this way of life. Pastoral nomads travel to find water and pastures for their herds. Bedouin herders move camels, sheep, and goats through the deserts of Arabia and northern Africa. The Fulani and their cattle travel through the grasslands of Niger in western Africa. Nomadic craftworkers and merchants, such as the Lohar blacksmiths of India and the Gypsy traders, travel to serve their customers. Nomadic peoples, especially herders, may also move to attack settled communities or avoid enemies.

Most nomads travel in groups of families called bands or tribes. These groups are based on kinship and marriage ties or on formal agreements of cooperation. A council of adult males makes most of the decisions, though some tribes have chiefs. The council-manager system, which is common in some parts of the world, is based on the principle that the council, rather than the individual, makes decisions. In this system, decisions are made by a council of elders, who are chosen for their wisdom and experience. The council meets periodically to discuss important issues and make decisions that affect the community. The council-manager system is common in many parts of the world, including the United States, where it is known as the council-manager form of government. Nome (pop. 3,505) is an important gold-mining center and port in Alaska. It lies along Norton Sound of the Bering Sea (see Alaska [political map]).

Gold mining is Nome's chief industry. The tourist and building industries and government agencies are also main sources of jobs. The port of Nome is open from June to October. Ice blocks it in winter. Eight airlines serve the region. The city has three radio stations and cable television. The Nome Nugget, first published in 1900, is Alaska's oldest newspaper.

Inuit (also called Eskimos) make up about half of Nome's people. Many Inuit hunt and fish to support themselves, and many also carve ivory ornaments and statues for sale. Nome is the finish for the Annual World-Classic Iditarod Trail Sled Dog Race, which begins in Anchorage, Alaska.

Nome sprang up suddenly in 1899, when gold was discovered nearby. Within a year, thousands of miners, merchants, and adventurers had set up a city of tents. The city got its name when a mapmaker misread the term ?name on a chart and recorded it as C. Nome, or Cape Nome. Nome was incorporated in 1901. By that year, prospectors could no longer find significant gold deposits, and many began to leave Nome. The city has a council-manager government.

Nominative case. See Case.
Nonaggression pact is a treaty by which two or more nations agree to settle mutual disputes peacefully and not to attack each other. Between World War I (1914-1918) and World War II (1939-1945), many nations signed nonaggression pacts because there was no international force strong enough to prevent aggression. Nonaggression pacts sometimes were not effective because they lacked enforcement procedures, and also because participating nations violated their agreements. For example, during the 1920's and 1930's, the Soviet Union signed pacts with many of its neighbors. But the Soviet Union violated its agreements with Estonia, Latvia, and Lithuania when it occupied them in 1939 and 1940. Germany signed a nonaggression pact with the Soviet Union in 1939 but attacked the Soviets in 1941.

Since the end of World War II, there have been fewer attempts to establish nonaggression pacts. Many nations feel that the United Nations Charter contains adequate provisions for the peaceful settlement of disputes. A major problem with nonaggression pacts is to decide an acceptable definition of aggression. The UN has debated this question but has not reached any agreement. Some nations believe aggression includes only direct military attacks. Others feel that when one country aids revolution in another country through propaganda, subversion, or by taking over government posts, it constitutes indirect aggression.

Nonpartisan League, nəhn PAHR tuh zuhn, a political organization of farmers, was founded in North Dakota in 1915. It is sometimes called the NPL. From 1916 to 1921, the NPL dominated the government of North Dakota, where it enacted many socialist policies. In 1919, the state legislature set up a state-owned bank, grain elevator, insurance fund, and other institutions important to farmers and workers. NPL candidates ran officially as Republicans. In Minnesota, the NPL helped create the Farmer-Labor Party (see Farmer-Labor Party).
During and after World War I (1914-1918), the NPL was criticized as unpatriotic because of its neutral position on the war and its socialist goals. Its power declined after 1921 but revived during the Great Depression of the 1930's. In 1956, the NPL aligned itself with the Democratic Party in North Dakota.

Nootka Indians, NOOT kuh, live along the west coast of Vancouver Island in British Columbia and at the tip of the Olympic Peninsula in Washington. Those on Vancouver Island call themselves the Nuu-chah-nulth or West Coast natives. Those living in Washington call themselves the Makah. There are more than 7,000 Nootka. They make their living mainly by fishing and lumbering in their traditional lands or by working in factories and offices in nearby cities. Many still speak dialects of the Nootkan language.

The Nootka were once noted for their skill in hunting whales from graceful dugout canoes. They lived in wooden plank houses on sheltered beaches and coves. Nootka artists carved and painted masks, large puppets, totem poles, and other objects used in religious ceremonies and in feasts called potlatches. The Nootka were first described in detail by the British navigator Captain James Cook in 1778. In the late 1700's and the 1800's, they were devastated by diseases introduced by Europeans, Americans, and Canadians. These peoples colonized most of the Nootka land. Robert S. Grumet

NORAD is a military alliance responsible for defending the United States and Canada against air attack. NORAD stands for North American Aerospace Defense Command. It oversees a large network of radars and other sensing devices that can detect and track approaching enemy bombers and missiles, artificial satellites, and other objects from earth in space.

NORAD was established in 1957. It has headquarters at Peterson Air Force Base near Colorado Springs, Colorado, and an underground command center at nearby Cheyenne Mountain. The commander in chief of NORAD is traditionally a general in the U.S. Air Force, and the second in command is a Canadian general. In the event of an attack, NORAD would relay information to the U.S. president and the Canadian prime minister, who would decide on a response. NORAD can oppose a bomber or cruise missile attack with antiaircraft missiles and fighter aircraft. The U.S. Air Force, Army, and Navy support NORAD through a unified command known as U.S. Space Command. Wayne Thompson

Nordenskjöld, NOOR duhn Sihnold, Nils Adolf Erik, nils AH dahlf AY riha (1832-1901), Baron Nordenskjöld, was a Swedish polar explorer, mineralogist, and map authority. In 1878 and 1879, he became the first person to sail through the Northeast Passage between the Atlantic and Pacific oceans. He sailed along the northern coast of Europe and Asia. He tells of this journey in his book, Voyage of the Vega (1881).

Nordenskjöld was born on Nov. 18, 1832, in Helsinki, Finland. He moved to Sweden in 1837 and became a Swedish citizen. He led two expeditions in an attempt to reach the North Pole. On the first one in 1868, he took his ship, the Sofia, to within about 575 miles (925 kilometers) of the Pole. Nordenskjöld studied the geology of Greenland in 1870. He returned there in 1883 and penetrated the ice barrier off the east coast. He determined that ice covered the island's interior. William Barr

Nordhoff and Hall were a team of American authors. Charles Bernard Nordhoff (1887-1947) and James Norman Hall (1887-1951) became famous for their three novels about an actual mutiny in the British Navy in 1789. These novels are Mutiny on the Bounty (1932), Men Against the Sea (1934), and Pitcairn's Island (1934). The first novel describes how the crew of the Bounty mutinied against their cruel captain, William Bligh. The second novel tells about the hardships of Bligh and his followers after they were set adrift in a small boat. The final novel follows the lives of the crew and their descendants after they settled on Pitcairn Island and Norfolk Island in the South Pacific Ocean.

Nordhoff was born on Feb. 1, 1887, in London, and Hall was born on April 22, 1887, in Colfax, Iowa. They met while serving as pilots in the Lafayette Escadrille, a French and American air squadron, during World War I (1914-1918). In 1920, they sailed for Tahiti, where they lived for many years. The men wrote several novels together as well as works individually. Samuel Chase Coale

Norfolk, NawR Huh, Virginia (pop. 234,403), is a leading United States port. It lies in southeastern Virginia (see Virginia [political map]). Norfolk is the state's second largest city. Only Virginia Beach has more people. Norfolk, Virginia Beach, and Newport News form a metropolitan area with 1,569,541 people.

Hampton Roads, one of the world's finest natural deepwater harbors, forms Norfolk's northwestern boundary. The Norfolk Naval Station employs more people and harbors more ships than any other naval base in the United States. It also serves as headquarters of the Allied Command Atlantic of the North Atlantic Treaty Organization (NATO).

In 1680, the Virginia General Assembly founded a port in Norfolk County to serve ships sailing to and from England and the West Indies. The port was later named Norfolk for the county. It became an independent borough in 1736 and an independent city in 1845.

Description. Norfolk covers 66 square miles (171 square kilometers). The Elizabeth River borders the city on the west, Chesapeake Bay is on the north.

Features of downtown Norfolk include a cultural and convention center called Scope. This complex includes

The Nootka Indians fished and hunted whales off the Northwest Coast of North America. They built houses of cedar planks.

Norfolk Island, /nuhrfuhl/, lies in the South Pacific Ocean, about 1,000 miles (1,600 kilometers) northeast of Sydney, Australia. For location, see Pacific Islands (map). Many of the island's inhabitants are descendants of crew members of the British naval ship Bounty. In 1789, those sailors of the Bounty mutinied against the way they were treated by their captain, William Bligh. They settled on Pitcairn Island in 1790. In 1856, 194 of their descendants moved to Norfolk Island.

Norfolk Island covers 14 square miles (36 square kilometers). It has a population of about 2,000. Tourism is the main source of income. Norfolk Island has fertile soil. The people grow bananas, citrus fruits, and vegetables.

In 1774, the British explorer James Cook became the first European to reach Norfolk Island. From 1788 to 1814, the island was used as a penal settlement by the Australian state of New South Wales. It again served as a penal settlement from 1825 until 1856, when the settlement was abolished. In 1914, the island was separated from New South Wales and became a territory of Australia. In 1979, the Norfolk Island Act set up a Legislative Assembly and Executive Council to handle local government matters on the island. The act preserved Australia's overall responsibility for the island.

W. W. Reid

**Norfolk terrier**, /nuhrfuhl/, is a breed of dog that originated in the United Kingdom. Norfolk terriers and Norwich terriers were exhibited at dog shows as one breed until 1964. That year, the Kennel Club in England registered them as separate breeds. The main difference between the two breeds is the way they carry their ears. Norfolk terriers have ears that drop forward, and Norwich terriers have ears that stand erect. The American Kennel Club recognized the dogs as separate breeds in 1979.

The Norfolk terrier is Hardy and active and instinctively hunts small animals. It was originally bred as a companion dog and makes a fine pet.

The Norfolk terrier may be black and tan, or any shade of red. It has a straight, wiry outer coat and a harsh undercoat. The dog has short, sturdy legs. The tail is sometimes docked (cut) to 3 or 4 inches (8 to 10 centimeters) in length. A full-grown Norfolk weighs from 10 to 12 pounds (4.5 to 5.4 kilograms).

**Norfolk Island**

Norfolk Island is a British overseas territory located in the South Pacific Ocean, about 1,000 miles (1,600 kilometers) northeast of Sydney, Australia. It is a lunar island, meaning it is not a true island but rather a low-lying area surrounded by the sea. The island is known for its beautiful beaches, coral reefs, and crystal-clear waters. The main language spoken on the island is English, and the official currency is the Australian dollar. Norfolk Island is home to a small population of about 2,000 people, many of whom are descendants of the Bounty mutineers who settled on the island in the late 18th century.

Norfolk Island has a rich history, and its location in the South Pacific Ocean has made it an important trading hub for centuries. The island was once a penal settlement, and its history is marked by a mixture of hardship and resilience. Today, Norfolk Island is a popular destination for tourists, who come to enjoy its natural beauty and relax in the warm, tropical climate.

The island is known for its stunning beaches, which are a popular destination for sunbathers and swimmers. The beaches are surrounded by coral reefs, which provide a habitat for a variety of fish and other marine life. Norfolk Island is also home to a number of other attractions, including the Norfolk Island Botanic Gardens, which features a variety of native and introduced plants.

Norfolk Island is a popular destination for bird watchers, who come to see the island's diverse range of bird species. The island is home to a number of rare and endangered bird species, including the Norfolk Island green pigeon and the Norfolk Island kea.

Norfolk Island is a self-governing territory of Australia, and it has its own government, including a legislative assembly and an executive council. The island is governed by a commissioner appointed by the Australian government.
Norgay, Tenzing. See Tenzing Norgay.

Noriega, nav' YAY gah, Manuel Antonio, mah NWEHL (1934- ), was a military leader who controlled Panama from 1983 to 1989. In December 1989, United States President George H. W. Bush ordered troops into Panama. Bush said the troops were a response to the killing of a U.S. marine lieutenant by Panamanian soldiers and charges of drug trafficking against Noriega. In January 1990, Noriega surrendered to U.S. officials and was taken to the United States to stand trial. In 1992, he was convicted on charges of drug trafficking, money laundering, and racketeering and was sent to prison. In 1993 and 1994, Panamanian courts convicted Noriega of involvement in the murders of two of his political opponents, and in 1999, a French court convicted him of money laundering. Noriega did not leave prison for any of those trials.

Noriega was born in Panama City. He graduated from a military academy in Peru in 1962. That year, Noriega enlisted in Panama's military, which soon made him a lieutenant. Following a military take-over of the government in 1968, he quickly rose through the ranks. Noriega became commander of Panama's military intelligence agency in 1970 and expanded his power because of the secret knowledge he possessed. Noriega took charge of the military in 1983 and became increasingly involved in the drug trade in Latin America. Beginning in 1987, the United States tried to force him to resign. In 1988, two U.S. federal grand juries in Florida indicted Noriega on charges of drug trafficking and racketeering.

Steve C. Ropp

Norman architecture is a regional adaptation of Romanesque architecture. It originated in Normandy in northwest France. The style reached its highest development in England during the late 1000s, after the Norman Conquest of 1066, and in the 1100s.

Norman architecture is noted for its massive character, development of the six-part vault ceiling, and the use of Celtic and Carolingian patterns of carved ornamentation. Examples of the style include the churches of St. Etienne and La Trinité in Caen, France, and Ely and Durham cathedrals in England.

J. William Rudd

See also Architecture (picture: Romanesque architecture).

Norman Conquest is the name given to the conquest of England in 1066 by William, Duke of Normandy. The duke, who was also known as William the Conqueror, led a Norman army across the English Channel into England (see Normans).

William was a proud and ruthless ruler and a vassal of the king of France. He hoped to follow his distant cousin, King Edward the Confessor, as king of England. William claimed that Edward had named him as his successor. The chief English contender for the throne was Harold, Earl of Wessex. But William also claimed that Harold, who had visited Normandy in 1064, had sworn a solemn oath to support William's claim to the throne. In 1066, King Edward died. The Anglo-Saxon Witan (Great Council) chose Harold as king (see Harold II).

William at once declared his right to the throne. He claimed to have the support of the pope and gathered an army from northern France. William landed in England without opposition at Pevensey, between Eastbourne and Hastings.

The Normans were aided in their successful landing by a chance happening. While Harold was waiting for the Normans to arrive, he got news that a Norwegian force had landed in the north of England. He hastened north and defeated the Norwegians. Meanwhile, William's forces landed on the unprotected coast. Harold then marched back across England. But as he neared Hastings, he was attacked by William on Oct. 14, 1066. This was the historic Battle of Hastings, which established the Norman rule of England. Harold was defeated and slain. William entered London and was crowned king of England on Christmas Day, 1066. At first, he tried to win over the English nobles. But they opposed him stubbornly, and he spent several years subduing them.

William established Norman rule in England on a strong foundation. He hesitated at no act that he thought would increase the power of the crown. William took almost all the land of the English nobility, keeping some of it for himself and dividing most of the rest among his Norman followers. William forced all landholders to swear loyalty to himself. In this way, he put all the lords of England under his direct control. In order to know the conditions in England, William directed the preparation of the famous Domesday Book, a survey of all the regions in his kingdom (see Domesday Book).

The descendants of the Normans became the ruling

Norman architecture flourished in England in the 1000s and 1100s. Ely Cathedral, shown here, is a masterpiece of the style.
class in England. For a time, they kept themselves aloof from the Anglo-Saxons and treated them as a conquered people. But as the years went by the Normans and the Anglo-Saxons intermarried. The two peoples, which even in the beginning were similar, blended into one. Today, many English families claim—though few can prove—descent from the Norman conquerors.

The Normans contributed much to the English language and to English literature and architecture. At first, the Normans spoke French. Later, the Norman French blended with the Germanic tongue of the Anglo-Saxons and became English. John Gillingham

Additional resources

Normandy is a region in northwestern France. It was named after the Norse people who conquered the area in the 800's. It lies along the English Channel coast between the regions of Picardy and Brittany (see France [political map]). Famous towns include Rouen, the capital of the old province; Le Havre, a leading port; Honfleur; Caen; Bayeux; and Cherbourg. The inhabitants are well known as sailors and farmers. The farmers specialize in dairying and raising fruits, especially apples for cider and brandy. Iron ore is mined near Caen. Tourism is an important industry along the coast.

In A.D. 911, the Carolingian king, Charles the Simple, granted much of what is now Normandy to the Norman chieftain Rollo, or Hrolf. One of Rollo's most famous descendants was William the Conqueror, who won the English crown after the Battle of Hastings in 1066. Events of the battle are pictured on the famous Bayeux Tapestry, a medieval wall-hanging housed in the William the Conqueror Center in Bayeux, France. Normandy was united with England during the reign of the English king Henry I (1100-1135). England and France struggled for control of Normandy during the Hundred Years' War. The English recovered the region twice, but finally lost it in 1449 to Charles VII, king of France. Joan of Arc became famous as the leader of French troops in the fight for Normandy.

Normandy attracted worldwide attention June 6, 1944, when Allied troops landed on its beaches. From Normandy, the Allies drove the Germans out of France. Many of the towns in Normandy were damaged in the fighting.

Hugh O. Clout

Normandy, Duke of. See William I, the Conqueror.

Normans were a group of Vikings, or Norsemen (Scandinavians), who first settled in northern France, then advanced into England, southern Italy, and Sicily. In the 800's, Norman warriors began their conquests by raiding French coasts and river valleys. By the early 900's, they had settled in the French territory near the mouth of the Seine River now known as Normandy. In 911, the Carolingian king, Charles the Simple, granted much of the region to the Norman chief, Rollo, or Hrolf, and Rollo became the king's vassal. The Normans became Christians and adopted French customs. Many became famous administrators, clergymen, and crusaders.

Norman power grew after 950. The Normans invaded the Rhineland, an area in present-day Germany. In 1066, under the leadership of William, Duke of Normandy, they conquered England. After the conquest, Norman influence spread steadily throughout what are now the United Kingdom and Ireland. (See William I, the Conqueror.) In the same period, Normans won great victories in other lands. Robert Guiscard (1015?-1085), son of Tancred of Hauteville, conquered southern Italy. Roger, another of Tancred's sons, took the island of Sicily from the Muslims. These two territories were later united in the famous kingdom of the Two Sicilies by Roger's son, Roger II. Major advances in architecture and sculpture occurred in the period of Norman domination in western Europe. An architectural style called Romanesque owed much to the Normans.

Malcolm Todd

Norodom Sihanouk (1922— ), NAWR uh dum SEE uh nuk, is the king of Cambodia. He has been an important figure in Cambodian politics since 1941.

Sihanouk was born in Phnom Penh. He became king in 1941. At that time, Cambodia was part of French Indochina. Sihanouk became a supporter of Cambodian independence. Cambodia became independent in 1953. In 1955, Sihanouk gave up the throne and was elected prime minister. He was elected head of state in 1960.

In 1970, during the Vietnam War, the prime minister, Lieutenant General Lon Nol, and Prince Sisowath Sirik Matak ousted Sihanouk and forced him into exile. Sihanouk had publicly proclaimed Cambodian neutrality in the war. But he secretly allowed North Vietnamese Communists—the enemies of the United States and South Vietnam—to establish bases in Cambodia.

In 1975, a Communist group called the Khmer Rouge gained control of Cambodia and set up a harsh political regime. Sihanouk was allowed to return to Cambodia as head of state, but he had no real political power.

In 1979, Vietnamese forces invaded Cambodia, and Sihanouk fled to China. A civil war broke out among the Khmer Rouge, the Vietnamese, and other Communist and non-Communist groups. The opposing groups signed a peace agreement in 1991 and elections were held. In 1993, a new National Assembly made Sihanouk king again.

Norris, Frank (1870-1902), was an American novelist and journalist and a leader of the naturalism movement. Norris believed that a novel should serve a moral purpose. "The novel with a purpose," he explained, "brings the tragedies and griefs of others to notice" and "proves that injustice, crime, and inequality do exist."

Benjamin Franklin Norris, Jr., was born in Chicago. He moved to San Francisco with his family. While attending the University of California, he came under the influence of French naturalist writer Émile Zola and began to write McTeague (1899), one of his finest novels. McTeague tells how economic circumstances, alcoholism, heredity, and chance compel a man to become a murderer.

Norris planned a three-novel series called Epic of the Wheat to tell about the production, distribution, and consumption of wheat in the United States. The Octopus (1901) dramatizes how a railroad controlled a group of wheat farmers. The book emphasizes the control of "forces," such as wheat and railroads, over people and groups. It ranks with McTeague as Norris's finest work. Both novels show the author's weakness for melodrama but illustrate his genius for revealing character and writing exciting action scenes. The second book of the series, The Pit, was published in 1903, after Norris died following an operation for appendicitis.

Norris, George William (1861-1944), was one of the great independent politicians of American public life. During his 40 years in Congress, he ignored party politics to fight for whatever he believed to be right.

Norris was elected to the United States House of Representatives as a Republican from Nebraska in 1902. He served for 10 years. In 1910, he led the fight to reduce the power of the speaker of the House. Norris was elected a U.S. senator from Nebraska in 1912. His main interest lay in developing public ownership of utilities. He wanted the U.S. government to develop the electric power of the Tennessee Valley River Valley, despite the policies of the Republican Party. In 1933, Congress passed his bill to create the Tennessee Valley Authority (TVA).

Norris realized the danger to the United States resulting from the rise of Nazism and Fascism in Europe. He supported aid to Britain in the early years of World War II. Norris was defeated for reelection in 1942. He was born in Sandusky County, Ohio.

Robert W. Cherny

Norris-La Guardia Act of 1932 was one of the first laws that encouraged labor union activity in the United States. It restricted federal courts from issuing injunctions (orders) to stop union activities, including strikes, that involved no violence. The law made it impossible to enforce yellow-dog contracts. Many employers had forced their workers to sign such agreements, in which the employees promised not to join or aid a union. The act was sponsored by Senator George W. Norris of Nebraska and Representative Fiorello H. La Guardia of New York, both Republicans.

Before Congress passed the Norris-La Guardia Act, an employer could obtain an injunction to stop any union activity that hurt the employer's business in any way. The act banned such injunctions unless the employer had made every possible effort to settle the dispute through negotiations with the union. The act also required an employer to prove that denial of an injunction would hurt the employer more than an injunction would hurt the union. The Taft-Hartley Act of 1947 allowed injunctions in certain other cases (see Taft-Hartley Act).

The Norris-La Guardia Act prohibited employers from suing employees for breaking yellow-dog contracts. Employers thus could not enforce the contracts, and so eventually stopped using them.

James G. Scoville

Norse mythology. See Mythology (Teutonic mythology).

Norsemen. See Vikings.

North, Lord (1732-1792), Frederick, Earl of Guilford, was British prime minister from 1770 to 1782. His shortsighted treatment of the American Colonies helped bring on the Revolutionary War (1775-1783).

North managed the House of Commons in the interests of the king, George III (see George III). Even when he disagreed with the king's policy, he did not oppose it. He supported the tea tax that became one of the causes of the Revolutionary War (see Boston Tea Party). As the war went on, North's administration became increasingly disorganized and demoralized. In 1782, he persuaded the king to accept his resignation. In 1783, he became joint secretary of state with Charles Fox but resigned after only nine months (see Fox, Charles J.).

North was born in London and attended Eton College and Oxford University. In 1734, his father had him elected to Parliament from a family-owned "pocket borough." He later served in the Treasury and the Privy Council. He became chancellor of the exchequer and leader of the House of Commons in 1767.

John L. Bulten
North America

North America, the third largest continent in area, extends from the Arctic Ocean in the north to South America in the south. Only Asia and Africa cover larger areas. North America ranks fourth among the continents in population, after Asia, Africa, and Europe.

North America includes Canada, Greenland, the United States, Mexico, Central America, and the islands of the Caribbean Sea. Canada and the United States make up what is sometimes called Anglo-America (English-America) because many of their settlers came from England. English is the dominant language in Anglo-America. Mexico, Central America, and the Caribbean islands are sometimes called Middle America because they lie between Anglo-America and South America. Spanish is the dominant language in Middle America, though English is spoken on many Caribbean islands.

Anglo-America has valuable supplies of coal, petroleum, natural gas, and other underground resources. It has thick forests and vast farmlands. Anglo-America produces about a third of the world's manufactured goods. It also exports more food than any other region in the world. Some Middle American countries, on the other hand, have few natural resources and little level farmland. They rank among the world's poor countries.

North America offers other contrasts. Its climate is the most varied of any continent. Northern ice-covered plains differ widely in temperature from sunny Caribbean beaches. The landscape ranges from magnificent mountain peaks to flat grasslands. Luxuriant redwood forests along the Pacific coast contrast sharply with the parched sands of the southwestern deserts. North America has the world's largest island, Greenland, and the world's largest freshwater lake, Lake Superior.

People

The earliest North Americans were Indians who came to the continent from Asia. Most scientists think they ar-

Facts in brief

Area: 9,347,000 mi² (24,208,000 km²). Greatest distances (mainland)—north-south, 4,500 mi (7,200 km); east-west, 4,000 mi (6,400 km). Population: Estimated 2002 population—495,369,000; population density, 53 per mi² (20 per km²).

Elevation: Highest—Mount McKinley in Alaska, 20,320 ft (6,194 m) above sea level. Lowest—near Badwater, Death Valley, California, 282 ft (86 m) below sea level.

Number of independent countries: 23.

John Edwin Coffman, the contributor of this article, is former Associate Professor of Geography at the University of Houston.
Few people live in the cold northern part of the continent or in its western deserts. Many large cities lie along the eastern Great Lakes, the St. Lawrence River, and the Atlantic coast from Massachusetts to Virginia. Since the 1950's, a number of people have moved from the Northernmost and Midwestern United States to California and states in the Southwest and along the Gulf coast. In Middle America, most people live in the cool highlands where the Indians originally settled. Mexico City, located in these highlands, is one of the world's largest metropolitan areas. Since 1900, many Mexicans, Puerto Ricans, and Cubans have moved to the United States.

**Ancestry.** Most North Americans are descendants of Europeans. Immigrants from every European country have settled in North America. More than a third of the people of the United States and nearly half of the people of Canada have ancestors from England, Ireland, Scotland, or Wales. More than a fourth of all Canadians have French ancestors. Most European ancestors of Middle Americans came from Spain.

*Each country and dependency in North America has a separate article in World Book.

*Includes 6,439 square miles (16,729 square kilometers) and 1,214,000 people for Hawaii.

Populations are 2002 estimates for independent countries and 2002 and earlier estimates for dependencies based on the latest figures from official government and United Nations sources.
Blacks make up 12 percent of the population of the United States. Most of the people of the Caribbean islands are descended from black Africans. Other Caribbean people are mulattoes, people of mixed black and white descent. See Mulatto.

Asians make up a small percentage of the population of North America. They began immigrating to the continent in the 1800's. Asian immigrants have come mainly from China, Indochina, Japan, Korea, and the Philippines.

Many of the Indians in the United States and Canada live on reservations. Indians occupy much of central Mexico and parts of Central America. Most of the people of Mexico and Central America are mestizos, people of mixed white and Indian ancestry. See Mestizo.

There are only about 136,000 Inuit and Aleuts in North America. They live in Alaska, northern Canada, and Greenland.

**Languages.** Most North Americans speak English, Spanish, or French. Generally, the various regions of the continent have retained the languages of the early European colonists. English is spoken throughout the United States and most of Canada. Both English and French are spoken in Quebec and some other parts of Canada. Almost all Mexicans and most of the people of Central America and the Caribbean islands speak Spanish, though French, English, or Dutch is the language of some areas. Many Indians and Inuit still use their native languages. For more information about the people of North America, see the People section of the various country, state, and province articles.

**The land.**

North America covers about 9,347,000 square miles (24,208,000 square kilometers), or about a sixth of the world's land area. The continent is roughly triangular in shape. The Arctic, Atlantic, and Pacific oceans border the three sides. At its northern end, North America stretches more than 5,400 miles (8,690 kilometers) from Alaska's Aleutian Islands to the Canadian island of Newfoundland. At the southern end of the continent, the narrowest parts of Panama are only about 30 miles (50 kilometers) wide. The greatest north-south distance spans about 5,400 miles (8,900 kilometers), from northern Greenland to Panama.

**Land regions.** North America has eight major land regions. They are (1) the Pacific Ranges and Lowlands, (2) the Western Plateaus, Basins, and Ranges, (3) the Rocky Mountains, (4) the Interior Plains, (5) the Canadian Shield, (6) the Appalachian Highlands, (7) the Coastal Lowlands, and (8) Central America and the Caribbean.

**Pacific Ranges and Lowlands** consist of two parallel mountain ranges that are separated by a series of valleys. The mountains extend from Alaska to Mexico. Fertile valleys between the mountain ranges are productive agricultural centers. The outer ranges include the Olympic Mountains in Washington and the coastal mountains of Oregon and California. The inland ranges have the continent's tallest peaks and some of its most spectacular scenery. Mount McKinley, North America's highest mountain, rises 20,320 feet (6,194 meters) in the Alaska Range. The inland mountains also include the Cascade Range, which features many volcanic peaks, and the Sierra Nevada of California. Much of this ruggedly beautiful area is preserved as national, state, and provincial parks.

**The Western Plateaus, Basins, and Ranges** lie between the Pacific ranges and the Rocky Mountains. This dry region includes the Yukon River Basin in Alaska and Canada, the Interior Plateau of British Columbia, the Colorado Plateau, the Great Basin centered in Nevada, and the Plateau of Mexico. Much of the copper, gold, lead, silver, and zinc produced in North America comes from this region. Its land features include the spectacular Grand Canyon. The lowest point in the Western Hemisphere is in Death Valley in California. It is 282 feet (86 meters) below sea level.

**The Rocky Mountains** form North America's largest mountain system. They run from Alaska to New Mexico, and extend southward into Mexico as the Sierra Madre Oriental. Thick forests cover the northern slopes, and the southern Rockies have rich deposits of minerals. The Rockies' scenic peaks make the region a popular recreation and tourist area.

**The Interior Plains** cover much of central Canada and the Midwestern United States. The eastern part of this flat, low-lying region is North America's most productive agricultural area. Corn and hogs rank among the leading products. The drier western part—the Great Plains—sup-
Tropical islands, including Aruba, shown here, dot the Caribbean Sea. Their beaches attract large numbers of tourists.

The Canadian Shield is a huge area of ancient rock that covers most of Canada east of the Great Plains and north of the Great Lakes. Few people live in this region because of the poor soil and cold climate. Many valuable minerals lie beneath its surface. Evergreen forests spread across the southern part of the region.

The Appalachian Highlands extend from the island of Newfoundland to Alabama. The region includes low, rounded mountains; plateaus; and valleys. One of the world’s most productive coal fields lies in the Allegheny Plateau, in the central part of the region. Hardwood forests grow in the northern and southern sections.

The Coastal Lowlands stretch along the Atlantic Ocean and the Gulf of Mexico, from New York City to Mexico’s Yucatán Peninsula. The rich soil in much of this region creates good farmland.

Central America and the Caribbean consist of the narrow bridge of land at the southern tip of North America and the islands in the Caribbean Sea. A chain of volcanoes forms a mountainous spine along the Pacific coast of Central America. Most of the Caribbean islands were created by volcanic eruptions. Others are coral and other limestone formations.

Rivers. West of the Rocky Mountains, the rivers of North America drain into the Pacific Ocean or the Gulf of California, an arm of the Pacific. East of the Rockies, rivers flow into the Arctic Ocean, Hudson Bay, the Atlantic Ocean, or the Gulf of Mexico. The high ridge of the Rockies that separates the waters is called the Great Divide, or the Continental Divide.

West of the Rockies, such rivers as the Yukon, Fraser, and Columbia rush to the Pacific through gaps in the coastal ranges. The Colorado River cuts through the Grand Canyon as it flows toward the Gulf of California.

The Mackenzie River, which forms part of Canada’s longest river system, flows from Great Slave Lake into the Arctic Ocean. Many Canadian streams and rivers empty into Hudson Bay. East of the Appalachian Moun-

tains, several short rivers, such as the Connecticut and the Hudson, drain into the Atlantic.

The continent’s longest river system, the Mississippi-Missouri-Ohio, flows into the Gulf of Mexico. This system, which is about 4,700 miles (7,600 kilometers) long, drains almost all of the United States between the Rockies and the Appalachian Mountains. The Rio Grande, which forms most of the border between the United States and Mexico, also empties into the gulf.

Lakes. Lake Superior is the largest freshwater lake in the world. It is one of the five Great Lakes, which make up part of North America’s most important inland waterway. Four of the Great Lakes—Superior, Huron, Erie, and Ontario—lie on the border between Canada and the United States. The fifth, Lake Michigan, lies entirely within the United States. A chain of big lakes extends northwest from the Great Lakes to Great Bear Lake, Canada’s largest lake. Utah’s Great Salt Lake, one of the natural wonders of North America, is saltier than the ocean.

Waterfalls. North America’s most famous waterfall is Niagara Falls, on the U.S.-Canadian border between Lake Erie and Lake Ontario. Niagara Falls consists of two waterfalls, the Horseshoe Falls and the American Falls. The Horseshoe Falls is only 167 feet (51 meters) high, but more water passes over it than over any other waterfall in North America. A number of higher falls—several more than 1,000 feet (300 meters) high—plunge through the Cascade Range and the Sierra Nevada. North America’s highest waterfall, Yosemite Falls, is a main attraction at Yosemite National Park in the Sierra Nevada. Yosemite Falls drops 2,425 feet (739 meters).

Deserts. Most North American deserts lie in the southwestern United States and northern Mexico. One vast dry area reaches from southern Idaho and Oregon into Mexico. It includes the Great Basin, the Mojave Desert and Death Valley, and the Sonoran Desert. Another area, the Chihuahuan Desert, extends from southern New Mexico through western Texas into Mexico.

Coastline and islands. North America has a longer total coastline than any other continent. Including the

Barren land like California’s Death Valley, shown here, covers much of the southwestern United States and northern Mexico.
Mountains line the Pacific and north Atlantic coasts, and many bays cut into the rocky land. Plains slope gently to the coasts along the Gulf of Mexico, the Caribbean Sea, and the Atlantic south of New York City. There, the coastline is relatively smooth and even.

A number of islands lie off the coasts of North America. Greenland is located in the North Atlantic Ocean. Although Greenland is part of North America, it is governed as a province of Denmark. Newfoundland and other islands lie off the Canadian coast in the Atlantic Ocean. In the Pacific Ocean, Vancouver and many other islands lie off Canada, and the Aleutian Islands extend westward from the tip of the Alaska Peninsula. The islands in the Caribbean Sea are called the West Indies. They include the Bahamas, the Greater Antilles, and the Lesser Antilles. Cuba, one of the Greater Antilles, is the largest Caribbean island.

Climate

North America is the only continent that has every kind of climate, from the dry, bitter cold of the Arctic to the steamy heat of the tropics. An ice sheet permanently covers the interior of Greenland, where the temperature almost never rises above freezing. In the North American tundra, the vast treeless plain of the far north, the temperature rises above freezing for only a short period each summer. In the low-lying areas of the far south, it is hot and rainy all the time.

Most of the rest of North America is cold in the winter and warm in the summer, with moderate precipitation. Some areas have mild winters and long, hot summers. Other areas have harsh winters and short summers. The highest temperature ever recorded in North America was 134 °F (57 °C) at Death Valley in 1913. The lowest temperature was −87 °F (−66 °C) at Northice in Greenland in 1954.

**Animal life**

North America has abundant animal life, which varies with the climate and plant life of each region. Caribou, musk oxen, polar bears, seals, snowy owls, whales, and wolverines live in the cold north. Jaguars, monkeys, and colorful birds are found in tropical Central America.

Rocky Mountain sheep and goats graze on the slopes of the Rockies. The southwestern deserts have a wide variety of lizards and rattlesnakes. Coyotes and prong-
horns—animals that are found only in North America—roam the Great Plains. The forests of Canada and the Eastern United States have beavers, black bears, deer, ermines, minks, moose, muskrats, and porcupines. Canadian geese, ducks, egrets, pelicans, and spoonbills are among the birds that winter in the marshes of the Coastal Lowlands, and alligators live in the coastal waters of the far south. Raccoons, skunks, and squirrels are common throughout the continent.

The oceans supply commercial fishing crews with valuable catches of flounder, salmon, and many other kinds of fish and shellfish. Crabs are plentiful in the northern Pacific, lobsters in the northern Atlantic, and menhaden all along the Atlantic coast. Shrimp and oysters are abundant in the Gulf of Mexico.

Certain kinds of wildlife have decreased sharply in number over the years. These include the bison (buffalo), the whooping crane, and the bald eagle. Game laws and the establishment of protected areas help such animals survive today.

Plant life

The plant life of North America is related to the continent's various climates. Nothing grows on Greenland's

---

**Animals of North America**

This map shows some of the many kinds of mammals, birds, and reptiles of North America. The continent's abundant animal life varies with each region's climate and plant life.

WORLD BOOK map
Only grasses, mosses, and lichens survive in the east cold plains that border the Arctic Ocean. A kind of moss called sphagnum or peat fills the marshes of the Canadian Shield and is an important export from this region. Huge saguaro cactuses and other cactus plants grow in the southwestern deserts. Short grasses and small bushlike plants such as tumbleweed cover the dry Great Plains.

Most of the rest of the continent has forests and level rolling grasslands called prairies. The prairies stretch across the center of the continent. The forests cover the continent’s western mountain regions, most of Canada, and the eastern half of the United States. A tropical rain forest grows along the Caribbean coast.

The finest North American forests are those along the Pacific coast. The towering redwoods stand there, as well as forests of cedar, fir, hemlock, and spruce.

The Canadian forests include fir, larch, pine, and spruce trees. Hardwood trees such as maple and beech grow in the Northeastern United States. Many of the trees that grow in Canada and the Northeastern United States are processed into wood pulp for newsprint. Hickory, oak, and pine trees fill the forests of the Southern United States. Central America’s tropical forests in-

Plants of North America
Some of North America’s trees, shrubs, and other plant life are pictured on this map. The continent’s plant life is related to its climates, which range from icecap to tropical.

WORLD BOOK map
include mahogany and rosewood trees, which are used in making furniture.

Agriculture

North America ranks third among the continents after Asia and Europe in agricultural production. Its farms grow about three-fifths of the world's soybeans and about half the world's corn, flaxseed, and sorghum grain. North American farms produce about a fourth of the world's citrus fruits and oats, and a fifth of its cotton and wheat. Farmers in the United States and Canada grow so much food that large quantities may be sent to other countries. For example, North America provides about half the world's grain exports.

Fertile soil and a favorable climate help make the Midwestern United States the agricultural heart of North America. Farmers throughout this area grow corn and other crops, and they raise cattle and hogs. The Great Plains region of Canada and the United States is a major wheat-growing area. Large cattle and sheep ranches cover the Western basins and plateaus. Irrigation enables farmers in these areas to produce such crops as alfalfa, cotton, fruits, and sugar beets. Corn, dry beans, and rice are important food crops throughout Middle

Agriculture and fishing in North America

This map shows the major uses of land in North America. It locates the chief agricultural products and shows the most important crops in large type. The map also shows the major fishing areas and the kinds of fish caught.

![Map of North America showing agricultural and fishing areas](image-url)
Mining and manufacturing in North America

This map shows the location of North America's chief mineral resources and manufacturing centers. Major mineral-producing areas are shown in large type, and lesser ones in small type.

---

**Americas**. Large plantations located in the region produce such crops as bananas, coffee, cotton, and sugar cane.

Only about 4 per cent of United States and Canadian workers farm. Most of the farmers own all or at least part of their land. In Middle America, about half the people farm, and few of them own their own land. Many work as laborers on large plantations. Some own or rent small plots of land on which they struggle to grow enough food to feed their families.

**Industry**

**Manufacturing.** North America ranks second to Europe among the continents in manufacturing. Together, the United States and Canada produce about a third of the world's manufactured goods. The continent's chief manufactured goods include automobiles and automobile parts, chemical products, and food products. Manufacturing employs about a fifth of all North American workers.

The Midwestern and Northeastern United States and the Canadian provinces of Ontario and Quebec have long been North America's major manufacturing centers. Since the mid-1900's, however, industry has expanded rapidly in the Southern United States and along its Pacific coast. The chief products from factories in these newer industrial areas include aircraft and missiles, computers and electronic components, and petroleum and petrochemicals (chemicals made from petroleum or natural gas). Manufacturing also has grown in Middle America. Cement and fertilizer are produced throughout the region. The Bahamas and Puerto Rico produce medicines and other goods.

**Mineral.** North America has large supplies of a broad range of minerals. The continent produces about two-fifths of the world's silver and about a third of its natural gas and nickel. North America also provides about a third of the world's supply of phosphate rock and potash, which are chiefly used to make fertilizer. About a fourth of the world's copper, crude oil, and lead comes from North America, as does five of its coal. Fewer than 1 per cent of all North American workers have jobs in mining.

Most of North America's petroleum and natural gas comes from the Great Plains region, Alaska, and offshore deposits in the Gulf of Mexico. Major coal fields lie in the Appalachian Plateau, the central United States, and the Rocky Mountain region. Metallic minerals come mainly from the Canadian Shield, the Rockies and other western mountains, and the Appalachian Highlands.

**Transportation and communication**

North America lies between the Atlantic and Pacific oceans in the middle of the world's major trade routes. The Panama Canal at the southern tip of the continent connects the two oceans. Large ports line North America's east and west coasts. New York City, New Orleans, and Houston handle the most cargo of ports that serve the Atlantic coast. The leading ports on the Pacific Coast are Valdez Harbor, Alaska; Vancouver, B.C.; and Long Beach, Calif.

The United States and southern Canada have one of the world's most highly developed transportation systems, including inland waterways, highways, and railroads. The Mississippi River system, the Great Lakes, and the St. Lawrence Seaway form North America's most important inland waterways. Highways and railroad tracks crisscross the United States and southern Canada. Few roads lead into northern Canada. In Mexico, paved roads and railroad lines link major cities. In Central America and the Caribbean, most local roads are unpaved, and most railroad companies are small, private lines that connect sugar or banana plantations with processing plants and ports.

North America has the world's best regional airline network. Most flights serve the large cities of the United States and southern Canada. The world's busiest airports are located in the United States.

North America also has the best communications system of any continent. Radios and televisions are common in U.S. and Canadian households. Many people in Middle American countries own radios, but televisions are less widespread. About 2,000 daily newspapers are published in North America. Most North American newspapers and radio and television broadcasting stations are privately owned, except in Cuba and Nicaragua, where the government controls most communications.

North American Aerospace Defense Command. See NORAD.

North American Free Trade Agreement (NAFTA) is a pact that unites Canada, Mexico, and the United States in one of the world’s largest free-trade zones. It builds on a free-trade agreement between the United States and Canada that became effective in 1989. NAFTA took effect in January 1994.

Under NAFTA, tariffs on most goods produced and sold in North America are to be gradually eliminated over 10 years. Trade of a few additional products will continue to be restricted for another 5 years. The first reductions took place in 1994.

NAFTA also establishes rights and obligations regarding trade in services, intellectual property, and international investment. These provisions could serve as models for future global and regional trade agreements.

NAFTA generated extensive opposition in the United States because of concerns that it would result in a loss of U.S. jobs. Opponents feared the job losses would result from increased Mexican imports and from a shift

United States, History of the
North Atlantic Treaty Organization (NATO) is a military alliance consisting of the United States, Canada, and 17 other countries. The 17 countries are Belgium, the Czech Republic, Denmark, France, Germany, Greece, Hungary, Iceland, Italy, Luxembourg, the Netherlands, Norway, Poland, Portugal, Spain, Turkey, and the United Kingdom.

Formed in 1949, NATO was set up largely to discourage an attack by the Soviet Union on the non-Communist nations of Western Europe. NATO also was established to keep the peace among former enemies in Western Europe. After World War II ended in 1945, an intense rivalry had developed between Communist countries, led by the Soviet Union, and non-Communist nations, led by the United States. This rivalry became known as the Cold War. In 1955, the Soviet Union and communist nations of Eastern Europe formed their own military alliance to oppose NATO. The Soviet-led alliance was called the Warsaw Pact.

In forming NATO, each member country agreed to eat an attack on any other member as an attack on itself. Militarily, the United States was—and still is—the alliance's most powerful member, in part because of its large supply of nuclear weapons. The NATO countries believed the Soviet Union would not attack Western Europe if such an attack would trigger war with the United States. NATO's policy is known as deterrence because it designed to deter (discourage) an attack. NATO's purpose, however, has been less clear since the Warsaw pact and the Soviet Union were dissolved in 1991.

Organization. NATO has a civilian branch and a military branch. The civilian branch includes the North Atlantic Council, the highest authority in NATO. The council consists of the heads of government of the NATO members or their representatives. A secretary-general heads the council.

NATO's military branch includes three commands: Allied Command Atlantic, Allied Command Channel, and Allied Command Europe. Allied Command Europe has additionally functioned as the heart of NATO. NATO's military commanders report to the Military Committee, which reports, in turn, to the North Atlantic Council. The Military Committee consists of the military chiefs of staff of all NATO nations.

History. NATO was formed as a result of the North Atlantic Treaty, which was signed by 12 countries in 1949. The countries were Belgium, Canada, Denmark, France, Iceland, Italy, Luxembourg, the Netherlands, Norway, Portugal, the United Kingdom, and the United States. Greece and Turkey joined NATO in 1952. West Germany joined in 1955. Germany replaced West Germany as a member in 1990, when West Germany and East Germany were united. Spain joined NATO in 1982. During the Cold War, NATO helped maintain peace in Europe through its policy of deterrence. But it also experienced disagreements among its members. United Nations officials generally insisted that NATO rely on nuclear weapons to deter a Soviet attack. But some people in NATO countries opposed the use of these weapons. In 1966, France pulled its troops out of the NATO military command, though it remained a NATO member. Before France withdrew its troops, NATO's central office had been in Paris. In 1967, NATO moved its headquarters to Brussels, Belgium.

In 1991, the Warsaw Pact was dissolved, and the Soviet Union broke apart into a number of independent states. Most of the states—and the Soviet Union's former allies in Eastern Europe—rejected Communism. Some people felt that without its traditional Communist enemies, NATO had lost its purpose and should disband. Some NATO leaders proposed offering membership in NATO to former Warsaw Pact lands. Other NATO leaders worried that offering membership to former Soviet allies might lead to a dangerous conflict with Russia.

To help resolve the uncertainty about NATO's future, the alliance began the Partnership for Peace program in 1994. Over 20 countries joined, including Russia. Most of the other countries that joined were Eastern European nations. The program provides for joint military planning and exercises with NATO members but does not involve formal membership. In 1999, the Czech Republic, Hungary, and Poland became NATO members.

In the 1990s, NATO became involved in civil wars in Bosnia-Herzegovina and Yugoslavia to stop the fighting in the two countries. NATO also entered the conflicts to stop efforts by Serbs to drive non-Serbs from most of Bosnia and from the Yugoslav region of Kosovo. In Bosnia, NATO attacked Bosnian Serb forces who were fighting the government of Bosnia-Herzegovina. The conflict ended in 1995, and NATO troops began serving as peacekeeping forces in Bosnia.

In Yugoslavia in 1999, NATO launched extensive air strikes against military targets in what became the closest thing to a real war ever fought by NATO. The targets included Serbian troops from the Yugoslav army who were fighting ethnic Albanian rebels in Kosovo. The bombing ended in June 1999 after Yugoslavia began withdrawing its troops from Kosovo. NATO troops then entered Kosovo as peacekeepers.

In 2001, NATO sent troops to Macedonia to help maintain a cease-fire agreement between Albanian rebels and the Macedonian government. The NATO troops were given the task of collecting and destroying the rebels' weapons.

Later that year, on September 11, terrorists crashed hijacked commercial airplanes into the World Trade Center in New York City and into the Pentagon Building near Washington, D.C. Following these incidents, NATO announced that it considered this attack on America as an attack on all NATO members.

In 2002, NATO and Russia established the NATO-Russia Council. The new body allows Russia and NATO to work together on a range of projects and policies, including counterterrorism, arms control, and crisis management. Gary B. Ostrower

Additional resources
North Carolina leads all the states of the United States in tobacco farming and in the manufacture of tobacco products. It also leads the nation in the production of textiles and wooden furniture.

Raleigh is North Carolina's capital. Charlotte is the state's largest city.

North Carolina is a Southern state with a long coastline on the Atlantic Ocean. Islands, reefs, and sand bars make its shores some of the most treacherous in the world. Many ships have been wrecked at Cape Hatteras by the rough seas and difficult currents. Cape Hatteras is called the Graveyard of the Atlantic.

The state stretches westward from the coast across swamps and fertile farms. The land rises through lovely

hills into industrial cities and towns. Rugged mountains cover much of the far western part of North Carolina. Mount Mitchell, which rises more than 1 1/2 miles (2 kilometers) above sea level, is the highest peak in the eastern United States.

Manufacturing is North Carolina's most important economic activity. Service industries are also a major part of the state's economy. The leading services include education, health care, private research, and retail trade.

Research Triangle Park, a large research complex in the Raleigh-Durham area, is an important center of research for the electronics, medical, and other industries. North Carolina is a leading state in raising chickens, hogs, and turkeys. The state's main crop is tobacco. Tobacco fields, with neat rows of tobacco plants, are scattered throughout North Carolina.

In 1584, English explorers looked for a suitable site for a settlement along the North Carolina coast. As a result, the first groups of English settlers in America built colonies on Roanoke Island off the coast in 1585 and 1587. The earlier group returned to England. The later group vanished from the island, leaving behind only a mystery.
Interesting facts about North Carolina

Virginia Dare, the first English child to be born in America, was born on Roanoke Island on Aug. 18, 1587. Nothing else is known about her, because the colony into which she was born mysteriously disappeared.

The first state governor to be impeached was William Woods Holden of North Carolina. He had gained a reputation for waste and corruption after two years in office. On March 22, 1871, he was removed from office by vote of the state legislature.

The first operating silver mine in the United States opened in 1838 near Lexington. The mine was later named the Silver Hill Mine. It no longer operates.

The first interstate railroad opened in 1833 between Blakely, in Northampton County, and Petersburg, Va. The 75-mile (120-kilometer) Petersburg Railroad helped to increase tobacco trade from the Roanoke Valley into Virginia. The town of Blakely no longer exists, but the railroad still operates as part of the Seaboard System Railroad.

The Cape Hatteras lightouse overlooks a part of North Carolina's Atlantic coast known for rough seas and difficult currents.

Charlotte is the largest city in North Carolina. It serves as a major financial, transportation, and wholesaling center.

Charlotte is the largest city in North Carolina. It serves as a major financial, transportation, and wholesaling center.

Murray and Associates, Inc.

that has puzzled the ages. This group has been named the Lost Colony. Virginia Dare, the first child born to English parents in America, was a member of the Lost Colony.

During colonial days, groups of patriots in North Carolina, such as the Sons of Liberty, defied English taxes and English rule. After the Revolutionary War began in 1775, North Carolina was the first colony to instruct its delegates at the Continental Congress to vote for independence.

Before the outbreak of the Civil War (1861-1865), North Carolina tried to preserve the Union even after most other Southern states had withdrawn. But after North Carolina left the Union, it did its best to help the Confederate cause. More than 10 Civil War battles were fought on North Carolina soil. About a fourth of all Confederate soldiers killed came from North Carolina.

North Carolina's nickname, the Tar Heel State, refers to one of the state's earliest products—tar. According to legend, some Confederate troops retreated during a fierce Civil War battle. They left the North Carolina soldiers to fight the Union soldiers alone. The North Carolinians supposedly threatened to put tar on the heels of the other Confederate soldiers so that they would "stick better in the next fight."
Symbols of North Carolina
The state flag, adopted in 1885, displays two dates. May 20, 1775, is the supposed date of the Mecklenburg Declaration of Independence proclaiming Mecklenburg County's independence from Britain. On April 12, 1776, North Carolina authorized its delegates to the Continental Congress to vote for independence. The state seal, adopted in 1984, also has these dates. The standing figure represents Liberty; the seated figure, Plenty.

North Carolina (brown) ranks 28th in size among all the states and 4th in size among the Southern States (yellow).

General information
Statehood: Nov. 21, 1789, the 12th state.
State abbreviations: N.C (traditional); NC (postal).
State motto: Esse Quam Videri (To Be, Rather Than to Seem).
State song: "The Old North State." Words by William Gaston; musical arrangement by Mrs. E. E. Randolph.

Land and climate
Area: 52,672 sq. mi. (136,421 km²), including 3,954 sq. mi. (10,241 km²) of inland water.
Elevation: Highest—Mount Mitchell, 6,684 ft (2,037 m) above sea level. Lowest—sea level along the Atlantic Ocean.
Coastline: 301 mi. (484 km).
Record high temperature: 110 °F (43 °C) at Fayetteville on Aug. 21, 1983.
Record low temperature: −34 °F (−37 °C) at Mount Mitchell near Asheville on Jan. 21, 1985.
Average January temperature: 41 °F (5 °C).
Average yearly precipitation: 50 in. (127 cm).

Important dates
The English established their first American colony at Roanoke Island.
Colonists in North Carolina began to resist enforcement of the British Stamp Act and other tax laws.

For information about tourism, write to: Department of Commerce, Division of Tourism, 4324 Mail Service Center, Raleigh, NC 27699-4324. The Web site at www.visitnc.com also provides information.

For information on the economy, write to: Department of Commerce, Division of Business and Industry Development, 4310 Mail Service Center, Raleigh, NC 27699-4310.

The state’s official Web site at www.nc.gov also provides a gateway to much information on North Carolina’s economy, government, and history.
Population. The 2000 United States census reported that North Carolina had 8,049,313 people. The state's population had increased 21 percent over the 1990 figure, which was 6,628,637. According to the 2000 census, North Carolina ranks 11th in population among the 50 states.

About two-thirds of North Carolina's people live in metropolitan areas (see Metropolitan area). Ten metropolitan areas lie entirely in North Carolina. These areas are Asheville, Fayetteville, Goldsboro, Greensboro-Winston-Salem-High Point, Greenville, Hickory-Morganton, Jacksonvill, Raleigh-Durham-Chapel Hill, Rocky Mount, and Wilmington. The Charlotte-Gastonia-Rock Hill area extends into South Carolina. The Norfolk-Virginia Beach-Newport News area includes Currituck County in North Carolina. For the populations of these areas, see the Index to the political map of North Carolina.

Charlotte is the state's largest city, with a population of about 540,000. North Carolina's other cities with more than 100,000 people, in order of population, include Raleigh, the state capital; Greensboro; Durham; Winston-Salem; and Fayetteville. All these cities lie inland. The state's largest coastal city is Wilmington, with a population of about 76,000.

About 22 of every 100 North Carolinians are African Americans. North Carolina's other large population groups include people whose ancestors came from England, Germany, Ireland, Northern Ireland, and Scotland. A number of North Carolinians are of American Indian descent.

Schools. Churches and religious leaders controlled most of the early education in North Carolina. In 1705,

Population density

About half of North Carolina's people live in a stretch of land that extends from Charlotte to the Atlantic Coast. This area includes most of the state's largest cities.
Universities and colleges

This table lists the universities and colleges in North Carolina that grant bachelor's or advanced degrees and are accredited by the Southern Association of Colleges and Schools.

*For campuses, see North Carolina, University of.

Charles Griffin, a schoolteacher and Anglican Church member, set up what was probably North Carolina's first school. It was at Symons Creek near Elizabeth City.

The Constitution of 1776 provided for the establishment of a public school system and for chartering the University of North Carolina. In 1795, this university became the first state university in the United States to hold classes. But North Carolina did not build its first public school until 1840. In 1901, Governor Charles B. Aycock began to improve the state's system of public education.

The State Board of Education supervises North Carolina's public school system and makes its policies. The board consists of the lieutenant governor, the state treasurer, and 11 other members who are appointed by the governor to eight-year terms. The state superintendent of public instruction, who is elected to a four-year term, serves as the chief administrator and secretary of the state board. Children from ages 7 through 15 must attend school. For the number of students and teachers in the state, see Education (table).

Duke University, in Durham, is named for James B. Duke, a tobacco millionaire who gave a large endowment to the school.

Libraries. The state's first public library was founded in Bath about 1700 by Thomas Bray, an English missionary. Bray established the first free lending libraries in the American Colonies. Bath was incorporated as a town in 1705, and it became the first town in North Carolina. In 1897, the state passed its first public-library law, and the state's first tax-supported library opened in Durham. Today, in addition to its public libraries, North Carolina has several cooperative library organizations that provide for the sharing of services and resources.

Libraries at Duke University and at the University of North Carolina at Chapel Hill own the largest collections of books in the state. Both universities have excellent collections of documents on Southern history and social sciences. The state library in Raleigh houses materials on the history of North Carolina. The archives and history division retains state records.

Museums. One of the outstanding art museums in the South, the North Carolina Museum of Art, opened in Raleigh in 1956. The University of North Carolina's art museums include the William Hayes Ackland Memorial Art Center in Chapel Hill and the Weatherspoon Art Gallery in Greensboro.

The North Carolina Museum of Natural Sciences, in Raleigh, features a large collection of specimens of prehistoric life. The Greensboro Historical Museum and the North Carolina Museum of History at Raleigh portray the history of the state.

The North Carolina Museum of Art, in Raleigh, opened in 1956. It houses the art collections of the state, which include a collection of old master paintings.
Many Northerners come to North Carolina's sandhills area for relief from the cold winter weather. Blossoming mountain laurels, azaleas, and rhododendrons in spring and summer, and the beautiful colors of autumn, lure visitors to the mountains. Hunters track quail and deer through the mountains. Swimmers, sunbathers, and people who like fishing enjoy North Carolina's lakes, rivers, and coastlines. Historic sites, battlefields, old mansions, and beautiful gardens attract sightseers and students of American history.

One of the most popular annual events in North Carolina is the performance of The Lost Colony. This historical drama is staged at Fort Raleigh in Manteo during June, July, and August. The play portrays some of the hardships faced by the early English colonists who disappeared mysteriously from Roanoke Island.

Places to visit

Following are brief descriptions of some of North Carolina's many interesting places to visit.

Alamance Battlefield, near Burlington, was the scene of a historic battle shortly before the Revolutionary War. About 2,000 frontiersmen, called the Regulators, rebelled against the eastern planters. The Regulators suffered a heroic defeat on May 16, 1771.

Battleship North Carolina Memorial is located on the Cape Fear River at Wilmington. Visitors may tour the U.S.S. North Carolina, a famous battleship that took part in every major offensive in the Pacific during World War II (1939-1945).

Bentonville Battlefield, near Smithfield, was the scene of one of the last important Civil War battles. There, in March 1865, General William T. Sherman's Union forces defeated the Confederate troops of General Joseph E. Johnston.

Biltmore Estate covers about 8,000 acres (3,200 hectares) of forests and farmlands in Asheville. The Biltmore House, a masterpiece of early French Renaissance architecture, is the chief feature of the estate.

Cherokee Indian Reservation, at Cherokee, includes a replica of an Indian village as it looked in the 1700's. Visitors can see demonstrations of Cherokee handicraft.

Chimney Rock is a unique rock formation that towers high above the mountains in Rutherford County. Chimney Rock offers an excellent view of the Blue Ridge Mountains.

Grandfather Mountain, near Linville, looks like the huge sleeping face of an old man. Tourists may walk across a swinging bridge 1 mile (1.6 kilometers) high.

Morehead Planetarium, at the University of North Carolina in Chapel Hill, is a widely known, planetarium. Spectators can watch the movements of stars and planets across a 68-foot (21-meter) dome.

Nantahala Gorge, in Swain County, plunges deep into the mountains. Indians in the region believed the gorge was haunted.

North Carolina Zoological Park, near Asheboro, has more than 700 animals and over 30,000 plants. It occupies 1,448 acres (586 hectares), making it one of the largest zoos in the world.

Ocracoke Island, a hideout of Blackbeard, the pirate, lies about 30 miles (48 kilometers) offshore, southeast of Pamlico Sound. The island was the site of many shipwrecks.

Old Salem is a restored colonial village in Winston-Salem. Moravians founded the village of Salem in 1766.

Pinehurst, a popular and charming resort village in the sandhills region, is famous for its peaceful atmosphere and its golf facilities.

Tryon Palace, in New Bern, is the restored governor's mansion originally built by William Tryon, a royal governor. American patriots defied British authority by meeting in the palace in 1774.

National parks, forests, and memorials. North Carolina has four national forests: Croatan, Nantahala, Pisgah, and Uwharrie. Several parts of Nantahala and Pisgah national forests have been set aside as national wilderness areas. North Carolina shares the Blue Ridge Parkway with Virginia, and the Great Smoky Mountains National Park with Tennessee (see Great Smoky Mountains National Park). The Wright Brothers National Memorial at Kill Devil Hills near Kitty Hawk honors the first powered airplane flight. For other areas, see National Park System (tables: National historic sites; National military parks; National battlefields; National lakeshores; National seashores).

State parks. North Carolina has 34 state parks. For information about them, write to Director, Division of Parks and Recreation, 1615 Mail Service Center, Raleigh, NC 27699-1615.
Annual events

January-March
Field Trials in Pinehurst (January); Christmas at the Homestead in Boone (January); Camellia Show in Wilmington (February); Horse Trials in Tryon (March); Moravian Easter Service in Old Salem (March or April).

April-June
Festival of Flowers at the Biltmore Estate in Asheville (April); Azalea Festival in Wilmington (April); Stoneybrook Steeplechase in Southern Pines (April); Shad Festival in Grifton (April); Ole Time Fiddler's and Bluegrass Festival in Union Grove (May); Annual Emerald Isle Beach Music Festival in Emerald Isle (May); National Hollerin' Contest in Spivey's Corner near Fayetteville (June); Summer Festival of Music in Brevard (June-August); Singing on the Mountain at Grandfather Mountain near Linville (June); Rhododendron Festival in the Bakersville area (June); The Lost Colony Outdoor Drama at Manteo (June-August).

July-September
Western North Carolina Wagon Train in Brevard (July); Bele Chere Festival in Asheville (July); Highland Games and Gathering of Scottish Clans at Grandfather Mountain (July); Mountain Dance and Folk Festival in Asheville (August); Annual Mount Mitchell Crafts Fair in Burnsville (August); State Championship Horse Show in Raleigh (September); Mule Days Celebration in Benson (September).

October-December
State Fair in Raleigh (October); National 500 Auto Race in Concord (October); Surf Fishing Tournament in Nags Head (October); Anniversary of First Powered Airplane Flight in Kill Devil Hills (December 17); Christmas at Biltmore in Asheville (December); Candlelight Christmas Tour of Historic Oakwood in Raleigh (December).

The Biltmore Estate in Asheville

The Lost Colony drama at Manteo

Grandfather Mountain near Linville
Land regions. North Carolina has three main land regions. These are, from east to west: (1) the Atlantic Coastal Plain, (2) the Piedmont, and (3) the Mountain Region.

The Atlantic Coastal Plain extends from New Jersey to southern Florida. North Carolina's coastal plain extends inland through an area of low, level marshland, covered by trees and water. Many swamps, shallow lakes, and rivers reflect moss-hung baldcypress trees. The Dismal Swamp in the northeast is one of the country's largest swamps. Treeless, grassy prairies cover parts of the eastern coastal plain. The western coastal plain has rich farmland. Sand hills rise along the southern part of the coastal plain.

The Piedmont is a hilly region that extends from Delaware to Alabama. In North Carolina, the Piedmont rises from about 300 feet (90 meters) at the edge of the coastal plain to about 1,500 feet (460 meters) at the mountains. The boundary between the Piedmont and the coastal plain is called the Fall Line. Along the Fall Line, rivers fall from the rocky Piedmont onto the softer, flat coastal plain. Most of the state's manufacturing industries are in the Piedmont. The area has more people than the coastal and mountain regions together.

The Mountain Region stretches from southern Pennsylvania to northern Georgia. The Blue Ridge Mountains are North Carolina's chief range. But the region also includes a number of other ranges. They include the Bald, Black, Brushy, Great Smoky, South, Stone, and Unaka ranges. All these mountains form part of the Appalachian Mountains. The Mountain Region rises from the Piedmont to heights of more than 1 mile (1.6 kilometers) above sea level. Mount Mitchell rises 6,684 feet (2,037 meters) and is the highest peak east of the Mississippi River. Forests cover much of the mountains, and the valley bottoms have good farmland. Great Smoky Mountains National Park and the Blue Ridge Parkway are in this region.

Coastline. The general coastline of the North Carolina mainland stretches 301 miles (484 kilometers). The tidal shoreline, which includes sand bars, islands, bays, and the mouths of rivers, measures 3,375 miles (5,432 kilometers). Sand bars, called the Outer Banks, form an almost continuous barrier along the coast. The Outer Banks jut into the Atlantic Ocean, forming Cape Fear, Cape Lookout, and Cape Hatteras. Their shifting sands have caused many shipwrecks. Cape Hatteras is called the Graveyard of the Atlantic.

Rivers, waterfalls, and lakes. Most of North Carolina's rivers start in the Mountain Region or in the Piedmont. They flow southeastward down the slopes of the western mountains and hills until they reach the edge of the Piedmont region. The rivers move through narrow channels above the Fall Line. Some flow through rapids where there is a noticeable drop at the Fall Line. Below the Fall Line, the rivers widen and flow slowly and then end in wide estuaries (river mouths). Boats can sail inland from the coast on several of the larger rivers as far west as the Fall Line.

One of the state's largest rivers, the Roanoke, flows into northeastern North Carolina, and empties into Albemarle Sound. The Neuse and Tar rivers drain the central part of North Carolina and flow into Pamlico Sound. The Cape Fear River crosses the southeastern portion of the Atlantic Coastal Plain. Several swift streams west of the Blue Ridge Mountains drain into Tennessee. North Carolina's largest dams are in this western area on the Hiwassee, Little Tennessee, and Nantahala rivers. Large dams also span the Catawba River, east of the Blue Ridge Mountains near Marion, and the Roanoke River near Roanoke Rapids.

Many lovely waterfalls add to the beauty of southwestern North Carolina. Whitewater Falls, near Brevard, plunges 411 feet (125 meters) and is one of the highest falls in the Eastern United States. North Carolina's only natural lakes are on the Atlantic Coastal Plain. Lake Mattamuskeet, the largest, is about 15 miles (24 kilometers) long and 6 miles (10 kilometers) wide.

Plant and animal life. Forests cover about 60 percent of North Carolina. Common trees include baldcypress, hickories, maples, oaks, pines, sweet gums, tupelos, white Cedars, and yellow-poplars. In January, camellias bloom along the coastline. By April, redbud and dogwood blossoms have spread across the state. In May and June, azaleas and rhododendrons color the moun-
tainsides. Orchids and such insect-eaters as pitcher plants, sundews, and Venus's-flytraps flourish in the coastal savannas.

Deer are found throughout the state. Black bears live in the western mountains and in the coastal lowlands. The fields, forests, and streams are filled with beavers, foxes, gray squirrels, opossums, otters, rabbits, raccoons, and skunks. Common songbirds include cardinals, Carolina wrens, and mockingbirds. Ducks, geese, and swans winter near the coast. Mourning doves, partridges, and woodcocks inhabit much of the state.

**Climate.** Temperatures in southeast North Carolina average 80°F (27°C) in July and 48°F (9°C) in January. The western mountains average 60 to 70°F (16 to 21°C) in July, and as low as 28°F (−2°C) in January. The state's highest recorded temperature was 110°F (43°C) at Fayetteville on Aug. 21, 1983. The lowest temperature recorded was −34°F (−33°C) at Mount Mitchell near Asheville on Jan. 21, 1985.

Rain makes up most of the state's precipitation (rain, melted snow, and other moisture). The Atlantic Coastal Plain averages about 50 inches (125 centimeters) a year, the Piedmont about 47 inches (120 centimeters), and the Mountain Region about 60 inches (150 centimeters). Snowfall ranges from 40 inches (100 centimeters) a year in some mountains to only a trace in some coastal areas. Because of the way its coastline juts into the Atlantic Ocean, North Carolina has often been the target of destructive hurricanes. The state experiences an average of one hurricane every four years.

**Average monthly weather**

**Average January temperatures**

North Carolina has short, mild winters. The southeastern part of the state has the warmest wintertime temperatures. The coolest temperatures are found in the mountainous western area.

**Average yearly precipitation**

North Carolina has a wet climate. The far west and the area along the Atlantic Ocean receive the most precipitation. Snow is usually concentrated in the mountains of the Mountain Region.

**Average July temperatures**

The state has hot summers with very little variation in temperature. Generally the southeastern section of North Carolina is somewhat warmer than the area to the northwest.

Economy

Service industries, taken together, account for about two-thirds of North Carolina's gross state product—the total value of goods and services produced in a state in a year. However, manufacturing is the single most important economic activity. It accounts for about a fourth of the gross state product. The leading manufactured goods are chemicals and tobacco products. Community, business, and personal services are the leading employer among North Carolina's service industries.

**Natural resources** of North Carolina include rich
soils and mineral deposits, and thick forests.

**Soil.** Red and yellow soils cover most of North Carolina, except along the coast and in the mountains. Light and level sandy loam soils make the central and western coastal plain the richest farmland in the state. A strip of coastal land that ranges from about 30 to 60 miles (50 to 100 kilometers) wide has marshy soils formed by dark peat or muck. Drained properly, these soils provide good farmland. Deep sandy soils cover the sand hills along the southern part of the Fall Line. The Piedmont has sandy, clay, and silt loams, mostly red in color. Strips of dark alluvial (water-deposited) soils lie along most of the streams. Grayish-brown loams cover most of the mountain area.

**Minerals.** North Carolina, sometimes called "Nature's Sample Case," has deposits of more than 300 different minerals and rocks. The mountains contain rich stores of feldspar and kaolin. The Mountain and Piedmont regions have large deposits of gneiss. Sand, gravel, and limestone are found throughout the state. The Piedmont region has clays, granite, and shale. Other mined products include phosphate rock and lithium.

**Forests** cover about 60 percent of the state. Oaks and pines are the most common trees. Oaks grow along with such other hardwoods as hickories, maples, and yellow-poplars over the entire state. Tupelo and sweet gum forests spread along the coastal plain rivers and streams. Loblolly pine, the state's most common softwood, grows over the entire coastal plain. Pond pine, black tupelo, baldcypress, and white-cedar are found in the swamps.

**Service industries** account for the largest part of North Carolina's gross state product. Most services are concentrated in the metropolitan areas.

Among North Carolina's service industries, (1) community, business, and personal services; (2) wholesale and retail trade; and (3) finance, insurance, and real estate each contribute about the same amount to the gross state product.

Community, business, and personal services employ more people than any other industry in the state. This group consists of establishments such as private health care, private schools and research facilities, motels, law firms, and repair shops. Duke University in Durham is a leading center of research for medicine and other fields. Research Triangle Park is a large research complex located in the Raleigh-Durham area. This complex is the home of many electronics and medical laboratories and specialized research facilities.

The wholesale trade of automobiles, building materials, groceries, and tobacco is important in the state. Lowe's Companies, one of the largest wholesale distributors of building materials in the United States, is headquartered in North Wilkesboro. Major retail businesses include department stores, food stores, and service stations.

Real estate businesses have benefited from the state's rapidly growing population and from the state's growing reputation as a commercial center. Charlotte is one of the country's major financial centers. Bank of America and Wachovia Corporation, two large banking companies, are based in the city.

Government ranks fourth among North Carolina's service industries. Government services include the operation of public schools, public hospitals, and military bases. North Carolina has one of the largest public university systems in the United States. Military bases in the state include Fort Bragg, Camp Lejeune Marine Corps Base, Cherry Point Marine Corps Air Station, and Seymour Johnson Air Force Base.

Transportation, communication, and utilities rank fifth among service industries. Carolina Freight, a major U.S. trucking company, is headquartered in Charlotte. Telephone companies are the major part of the communications sector. Duke Power and Carolina Power & Light are the largest utility companies in North Carolina. More information about transportation and communication appears later in this section.

**Manufacturing** accounts for a larger portion of the gross state product in North Carolina than it does in most other states. Goods made in the state have a value added by manufacture of about $83 billion a year. Value added by manufacture represents the increase in value of raw materials after they become finished products.

Chemicals rank first among North Carolina's manufactured products in terms of value added by manufacture. Pharmaceuticals and synthetic fibers are the leading chemical products. Factories in Durham, McDowell, and Wake counties make pharmaceuticals. Large plants that produce synthetic fibers operate in Enka, Kinston, Salisbury, Shelby, and Southport.

Tobacco products rank second among the state's manufactured goods. North Carolina makes more tobacco products than any other state. Factories in Greensboro, Reidsville, and Winston-Salem produce about half of the nation's cigarettes. In addition, Winston-Salem has plants that make chewing and pipe tobacco.

Textiles rank third among the state's manufactured products. North Carolina leads the United States in textile production. North Carolina has about 720 textile plants. Gaston County cotton mills spin more yarn than any other U.S. county. North Carolina makes about half the nation's hosiery. Greensboro has the world's largest mill for weaving denim. Other textile products made in

*GDP = gross state product, the total value of goods and services produced in a year.

†Less than one-half of 1 percent.

North Carolina include carpeting, synthetic fabric, and household textiles, such as sheets and towels.

Computer and electronic products are fourth in terms of value added. Communications equipment and computer components are the leading electronic products.

Other products manufactured in North Carolina include food products, furniture, machinery, and rubber and plastic products. Baked goods, beverages, and meat products are the leading food products. North Carolina leads the states in the production of household furniture, and High Point is often called the Furniture Capital of America. Factories in many towns produce wooden furniture. Important types of machinery made in North Carolina include construction equipment, industrial machinery, and refrigeration equipment. Various plastic products are made throughout the state.

Agriculture. Farmland covers about 30 percent of North Carolina. The state has approximately 56,000 farms. Livestock products and crops each provide about half of North Carolina’s agricultural income.

North Carolina ranks among the leading states in both chicken production and hog production. Hogs provide the most income of all livestock products in the state. Most hogs are raised in the eastern part of the state. Broilers (chickens from 5 to 12 weeks old), are the second most valuable livestock product. The largest number of broilers come from Chatham, Moore, Randolph, and Union counties.

North Carolina raises more turkeys than any other state. Duplin, Sampson, Union, and Wayne counties raise the most turkeys. Dairy farming is important in the western part of the state. Other livestock products in North Carolina include beef cattle, eggs, and ducks.

Tobacco is North Carolina’s leading crop. Fire-cured tobacco is grown in many parts of the state. More fire-cured tobacco is sold in Wilson than in any other city in the United States. Burley tobacco is grown in mountainous areas near Asheville. Corn and soybeans also rank as important crops. Both grow in the eastern part of the state, and both are used largely for livestock feed. Soybeans are also used to make oil.

North Carolina is a leading state in growing peanuts and sweet potatoes. Peanuts grow chiefly in the northern coastal plain. Sweet potatoes grow in the warm, humid regions of the western coastal plain. Apples are the leading fruit crop. Blueberries, peaches, and strawberries are also important. North Carolina’s other agricultural products include cotton, greenhouse and nursery products, hay, trees, and wheat.

Mining. Crushed stone, mainly granite, is North Carolina’s leading mined product. Limestone and traprock are also mined from the state’s quarries.

Other leading mined products of North Carolina are phosphate rock and sand and gravel. Phosphate rock is mined in Beaufort County. It is used to make fertilizers. Sand and gravel, used in construction and grassmaking, are produced mainly in the coastal plain.

North Carolina is a leading producer of feldspar, mica, and pyrophyllite. The state’s other mined products include clays, granite, marble, olivine, and talc.

Fishing industry. North Carolina’s annual fish catch is valued at about $100 million. The most valuable fish and shellfish caught are blue crabs, clams, flounder, shrimp, and trout. The Beaufort-Morehead City area is a leading U.S. fishing port. North Carolina’s aquaculture industry raises catfish, crayfish, Atlantic menhaden, and trout in natural and artificially created bodies of water.

Electric power. About two-thirds of the electric power used in North Carolina is generated within the state. Most of the rest is generated in South Carolina. Of the power generated within North Carolina, about 60 percent comes from power plants that burn coal. Nuclear plants provide about 35 percent. Most of the remaining power comes from hydroelectric plants.

Transportation. Rivers served as the first highways in North Carolina. Roads began to appear in the 1700’s but most remained poor until well into the 1900’s. The state began a major campaign to improve its roads in the 1920’s. The first two major railroads—The Wilmington and Raleigh, and the Raleigh and Gaston—began service in 1840. At that time, the 161-mile (259-kilometer) Wilmington line was the longest in the world.
Today, seven interstate highways link North Carolina's 115 cities. Many bridges span inlets and rivers along the state's coast. About 25 rail lines provide freight service, and passenger trains serve 18 cities. The state's busiest port is at Charlotte. The Raleigh-Durham area and Greensboro also have major airports. Harbors at Morehead City, Southport, and Wilmington are part of the Atlantic Intracoastal Waterway (see Atlantic Intracoastal Waterway).

Communication. James Davis, a printer and editor, established North Carolina's first newspaper, the *North Carolina Gazette*, at New Bern in 1751. The weekly *Raleigh Register* was founded in 1799. The state's largest daily newspapers today are the *Charlotte Observer* and *The News and Observer* of Raleigh. North Carolina publishers print about 220 newspapers, of which about 50 are dailies, and about 150 periodicals.

North Carolina's oldest radio station, WBT of Charlotte, began broadcasting in 1922. Television in the state started in 1949, with stations WBTV in Charlotte and WFMV in Greensboro. Today, North Carolina has about 420 radio stations and 40 television stations. Cable television systems and Internet providers serve a large number of North Carolina communities.

**Government**

**Constitution** of North Carolina became effective in 1771. The state had two earlier constitutions, adopted in 1776 and 1868. Amendments to the Constitution can be proposed in the state legislature or by a constitutional convention. An amendment proposed in the legislature must be approved by three-fifths of both houses. Then it must be approved by a majority of the voters in a general election. A constitutional convention must be approved by two-thirds of both houses, and by the voters, before it can meet to propose and adopt amendments to the Constitution.

**Executive.** North Carolina's governor and lieutenant governor serve a four-year term and may be reelected only once. The governor can appoint a number of important state officials, including the heads of nine executive departments. The voters elect eight other top administrative officers to four-year terms. They are the attorney general, auditor, secretary of state, superintendent of public instruction, treasurer, and commissioners of agriculture, labor, and insurance. These officials and the lieutenant governor make up the council of state, an advisory council to the governor.

**Legislature** of North Carolina is called the General Assembly. It consists of a 50-member Senate and a 120-member House of Representatives. Senators are elected from 42 senatorial districts. Representatives are elected from 98 representative districts. Members of both houses serve two-year terms. The lieutenant governor is president of the Senate. The House of Representatives elects a speaker to preside over it. The legislature meets every year. In odd-numbered years, it has a regular session that begins on the Wednesday after the second Wednesday in January. In even-numbered years, a short session is held, usually in June, to review financial matters and conclude any business from the previous year. In 1965, a federal court ordered North Carolina to reapportion its districts to provide equal representation. The General Assembly reapportioned the districts in 1966. The legislative districts were reapportioned again in 1971, 1982, 1984, 1991, and 1997.

**Courts.** North Carolina's court system has three divisions: an appellate division, a superior court division, and a district court division. The appellate division consists of the Supreme Court, the state's highest court; and the court of appeals, an intermediate appellate court. The appellate courts hear cases appealed from lower courts. The Supreme Court has a chief justice and six associate justices, and the court of appeals has 12 judges.

The superior and district court divisions consist of 60 judicial districts. Each district is served by one or more superior court judges who hear civil and criminal trials. Each district also has two or more district court judges who handle minor civil and criminal cases.

Supreme court justices, court of appeals judges, and superior court judges are elected to eight-year terms. District court judges are elected to four-year terms. If any leaves office, the governor appoints a successor.

**Local government.** North Carolina has 100 counties. Each county is governed by a board of county commissioners. The boards consist of three to seven members, elected to two- or four-year terms, depending on the county. They meet monthly to supervise county affairs, and to perform such duties as appropriating funds and levying taxes. County officials include the sheriff, register of deeds, superior court clerk, county manager, finance officer, attorney, and tax officials.

State laws grant cities and towns home rule (self-government) to the extent that they may make certain amendments to their charters. But supervision and control remain in the hands of the General Assembly. North Carolina has more than 300 incorporated municipalities. An area may incorporate by petitioning the General Assembly. Most of the larger cities have the council-manager form of government. Other forms of municipal government are mayor-council and commission.

**Revenue.** Taxes account for about 55 percent of the state government's general revenue (income). Federal grants and other U.S. government programs make up most of the rest. A personal income tax provides the greatest portion of the tax revenue. Other important tax revenue sources in North Carolina include a general sales tax and taxes on motor fuels, corporate income, and public utilities.

**Politics.** The Democratic Party traditionally has dominated the state's politics. But Republicans have gained strength since the mid-1960's. From the Reconstruction period (1865-1877) through 1964, the Republican presidential candidate won the state's electoral votes only in 1928. But since 1968, the Republican has won in all of the presidential elections except 1976. For North Carolina's voting record in presidential elections, see Electoral College (table). In 1972, James E. Holshouser, Jr., became the first Republican to be elected governor of North Carolina since 1896. Also in 1972, Jesse A. Helms became the first Republican elected to the U.S. Senate from the state since 1895.
Indian days. About 35,000 Indians, belonging to about 30 tribes, lived in the North Carolina region when Europeans first arrived. The most important tribes were the Cherokee in the western mountains; the Hatteras along the coast; and the Catawba, Chowanoc, and Tuscarora of the coastal plain and the Piedmont.

Exploration and settlement. Giovanni da Verrazano, sailing in the service of France, was the first known European to explore the North Carolina coast. He visited the Cape Fear area in 1524. Verrazano sent glowing reports of what he saw to King Francis I of France. But the king was not interested in colonizing the region. Two years later, an expedition led by Lucas Vázquez de Ayllón de Spain may have stopped near Cape Fear to scout for a place to settle. Vázquez and his followers decided the area was unsuitable, and the expedition moved farther south to settle on the coast of South Carolina or Georgia. In 1540, Hernando de Soto of Spain led an expedition over the mountains at the southwestern tip of the North Carolina region. He hoped to find gold. Instead, he became the first European to reach the Mississippi River. He arrived at the river in 1541. Other Spaniards also came to the region, but neither they nor the French established any permanent settlements.

In 1584, Sir Walter Raleigh of England sent explorers to the North Carolina coast to find a suitable site for a settlement. The next year, the first English colony in America was established on Roanoke Island. But misfortunes forced the settlers to return to England in 1586. Raleigh sent a later expedition to Roanoke Island in 1587, with John White as governor. White established a colony and sailed back to England for supplies that same year. When Queen Elizabeth allowed White to return to Roanoke Island in 1590, his colony had disappeared. No one knows what happened to the more than a hundred men, women, and children of what has come to be called the Lost Colony (see Lost Colony).

In 1629, King Charles I of England granted his attorney general, Sir Robert Heath, the southern part of the English claim in America. This included a strip of land containing what is now both North Carolina and South Carolina, and extending to the Pacific Ocean. The land was named the Province of Carolina (land of Charles). Heath attempts at settlement failed.

The first permanent European settlers in Carolina came from Virginia. They settled in the Albemarle Sound region around 1650. In 1663, Charles II of England regranted Carolina to eight of his favorite nobles. He made them lords proprietors (ruining landlords). These men divided Carolina into three counties: (1)
Historic North Carolina

The Lost Colony was a group of more than 100 colonists that settled on Roanoke Island in 1587. Three years later, a supply ship found the colony had disappeared. One of its only traces was the word *Croatoan* carved on a tree.

The Sons of Liberty led demonstrations against a series of taxes imposed by England before the Revolutionary War.

The tobacco industry grew rapidly in North Carolina after the Civil War. Tobacco factories in the state numbered nearly 130 by 1880.

Important dates in North Carolina

1524 Giovanni da Verrazzano, a Florentine explorer sailing for France, visited the North Carolina coast.

1585 The English established at Roanoke Island their first colony in what is now the United States.

1629 King Charles I of England granted *Carolina* to Sir Robert Heath.

1650? The first permanent settlers came to the Albemarle region from Virginia.

1663 King Charles II granted the Carolina colony to eight lords proprietors.

1664 North Carolina's first permanent government was established in Albemarle County.

1711 The Tuscarora Indians attacked settlements between the Neuse and Pamlico rivers. The colonists defeated the Indians in 1713.

1729 North Carolina came under direct royal rule.

1765 Colonists in North Carolina began to resist enforcement of the British Stamp Act and other tax laws.

1774 North Carolina sent delegates to the First Continental Congress in Philadelphia.

1776 The Whigs defeated the Tories at Moore's Creek Bridge. North Carolina adopted its first constitution.

1781 British forces withdrew from North Carolina and surrendered in Virginia.

1789 North Carolina ratified the Constitution and became the 12th state on November 21.

1835 Constitutional changes gave greater representation to the counties of western North Carolina.

1861 North Carolina seceded from the Union.

1865 General Joseph E. Johnston surrendered to General William T. Sherman near Durham.

1868 North Carolina was readmitted to the Union.

1901 Governor Charles B. Aycock began a campaign to improve North Carolina public schools.

1903 The Wright brothers made the first successful powered airplane flight near Kitty Hawk.

1915 The state legislature set up a highway commission.

1933 The state took over the support of public schools.

1949 The people approved a large bond issue for road and public-school construction.

1950 Great industrial expansion began.

1959 The North Carolina Research Triangle Park, operated by three of the state's universities, opened.

1960 Four black students launched the sit-in movement at a lunch counter in Greensboro.

1971 A new state Constitution went into effect.

1972 James E. Holshouser, Jr., became the first Republican to be elected governor of North Carolina since 1896.

1989 North Carolina marked the bicentennial (200th anniversary) of its statehood.
Albemarle, in the northern part; (2) Clarendon, in the Cape Fear region; and (3) Craven, in what is now South Carolina. In 1664, William Drummond was appointed governor of Albemarle County, and government began in Carolina. Clarendon County lasted only until 1667. From then until 1689, Albemarle County had the only government in the North Carolina region.

**Colonial days.** The colonists of Albemarle County believed that the proprietors and governors were more interested in making money than in governing wisely. In 1677, some Albemarle colonists revolted against their governor. They ran the county for over a year by themselves. The revolt became known as Culpeper's Rebellion after John Culpeper, one of the leaders of the uprising. Between 1664 and 1689, the colonists drove five Albemarle governors from office.

After 1691, governors were appointed to govern the entire Carolina colony, with a deputy governor for the North Carolina region. The deputy governors ruled wisely and the colonists accepted them. The North Carolina region became a separate colony in 1712.

During the late 1600s and early 1700s, increasing numbers of settlers came to North Carolina. In 1705, North Carolina's first town, Bath, was incorporated near the mouth of the Pamlico River. By 1710, settlements had spread down the coast and along the riverbanks as far south as the Neuse River. In 1710, Swiss and Germans founded New Bern, a community several miles inland on the Neuse, in Tuscarora Indian territory. At dawn on Sept. 22, 1711, enraged Tuscarora Indians, whose land had been seized by European settlers, attacked New Bern and other settlements. Within two hours, most of the settlements between the Neuse and Pamlico rivers lay in ruins. The Indians had massacred hundreds of settlers, burned their homes, stolen their valuables, and destroyed their crops. The massacre marked the beginning of the Tuscarora War, the worst Indian war in North Carolina's history. The colonists defeated the Indians on March 25, 1713.

While settlers battled the wilderness and the Indians during the late 1600s and early 1700s, pirates terrorized North Carolina's coastline. Most piracy along the Atlantic Coast ended with the death of the pirate Blackbeard in a battle near Ocracoke Island in 1718.

In 1729, the lords proprietors sold their land back to the king of the United Kingdom. North Carolina became a royal colony, ruled by royal governors named by the king. The governors ruled wisely and helped the colony grow. In 1729, only about 36,000 people lived in North Carolina, mostly along the coast. By 1775, the population had grown to nearly 350,000, and settlement had spread westward across the Piedmont and into the mountains.

North Carolina contributed money and troops to help the United Kingdom fight several colonial wars. Those wars included Queen Anne's War (1702-1713), King George's War (1744-1748), and the French and Indian War (1754-1763). In 1760, Hugh Waddell of Wilmington led North Carolina troops to an important victory over the Cherokee Indians at Fort Dobbs, near present-day Statesville. In 1761, the Cherokee signed a peace treaty that opened a vast area of western Virginia and the Carolinas to settlement. See French and Indian wars.

**Revolution and independence.** The United Kingdom placed additional taxes on the American Colonies to help pay for the colonial wars. But the colonists objected to taxes levied without their consent. Protestors in North Carolina and other colonies called the Sons of Liberty led demonstrations and even armed rebellions against these taxes. Meanwhile, some farmers in western North Carolina rose up against the high taxes and dishonest officials forced upon them by the wealthy eastern planters. The western rebels were called the Regulators. William Tryon, the royal governor, needed more than a thousand troops to defeat the Regulators at the Battle of Alamance on May 16, 1771.

North Carolina sent delegates to Philadelphia to attend the First Continental Congress in 1774. After the Revolutionary War began in April 1775, North Carolinians quickly took sides. Those who opposed the British were called Whigs. Those who remained loyal to the king were called Tories. On Feb. 27, 1776, Whig forces, under Colonels Richard Caswell and Alexander Lillington, crushed the Tories in the Battle of Moore's Creek Bridge. This was the first battle of the Revolutionary War in North Carolina. The Whig victory prevented a planned British invasion of North Carolina. On April 12, 1776, North Carolina became the first colony to instruct its delegates to the Continental Congress to vote for independence. Later that year, North Carolina adopted its first constitution and chose Caswell as governor. On July 21, 1778, North Carolina ratified (approved) the Articles of Confederation.

Much of the Revolutionary War was fought outside North Carolina's borders. But North Carolinians joined the fight against the British in Virginia, Georgia, and South Carolina. Inside the state, warfare between Whigs and Tories produced much bloodshed and bitterness. In 1780, British forces led by Lord Charles Cornwallis marched toward North Carolina from the south. Part of Cornwallis's army was slaughtered in the Battle of Kings Mountain, just south of North Carolina. But after a retreat, Cornwallis moved northward again, this time into North Carolina. On March 15, 1781, Cornwallis's troops outlasted the American General Nathanael Greene's forces in the Battle of Guilford Courthouse. But the severely weakened British abandoned North Carolina soon afterward.

**Statehood.** North Carolinians delayed approving the United States Constitution because they opposed a strong federal government. At the Hillsborough Convention of 1788, they rejected the Constitution and suggested many amendments to it. The Bill of Rights to the Constitution, proposed by Congress in 1789, included some of these suggestions. North Carolina finally ratified the Constitution on Nov. 21, 1789.

During the early 1800s, North Carolina was a backward state. It had little commerce or industry. It lacked seaports and transportation facilities. North Carolina planters relied heavily on slave labor, and black slaves made up about a third of the population. Many people left North Carolina, including three men who later became president—Andrew Jackson, James K. Polk, and Andrew Johnson.

North Carolina began to progress in 1835, after revising its Constitution. The new Constitution gave greater representation to the people of the western region and encouraged the development of that area. Public schools, railroads, and roads were built. Agriculture in-
creased, and manufacturing started to grow. North Carolina led the nation in gold production until the California Gold Rush of 1849.

**The Civil War and Reconstruction.** Although North Carolina was part of the South, it tried to preserve the Union even after most other Southern states had seceded (withdrawn). The Civil War began on April 12, 1861. When President Abraham Lincoln asked for troops to fight the Confederate States, North Carolina refused. The state seceded from the Union on May 20, 1861. Union forces captured much of North Carolina’s coastline early in the war. But the port at Wilmington remained open to Confederate supply ships until January 1865. More than 10 battles took place in North Carolina. The bloodiest of these was fought at Bentonville from March 19 to 21, 1865. There, Union forces under General William T. Sherman defeated the Confederate troops of General Joseph E. Johnston. Johnston surrendered to Sherman near Durham on April 26. North Carolina supplied 125,000 men to the Confederate cause. About a fourth of all the Confederate soldiers killed came from North Carolina. However, many North Carolinians sympathized with the Union and resisted the Confederacy.

During the Reconstruction period, federal troops supervised the state’s government until 1868. That year, a new state Constitution abolished slavery and gave blacks the right to vote. The Republican Party then gained control of North Carolina. Its members included blacks, white Union sympathizers, and a few Northerners called carpetbaggers (see Carpetbaggers). The state rejoined the Union on June 25, 1868.

During the Reconstruction years, bitter struggles took place between Republicans and Democrats, and between blacks and whites. The Ku Klux Klan and other secret groups supported white supremacy and tried to keep blacks from voting. Democrats gained control of the state legislature in 1870. They impeached Republican Governor William W. Holden in 1871, and removed him from office. In 1875, the Democratic legislature added 30 amendments to the Constitution, thus ensuring white, Democratic control of county government.

**Economic progress.** The Civil War had brought death and destruction to North Carolina. But it also freed about 350,000 of the state’s black slaves. After slavery was abolished, North Carolina planters divided their land into small farms. They rented these farms to tenant farmers for a share of the crop. Under this system of sharecropping, the number of farms in the state grew from about 75,000 in 1860 to 150,000 in 1880.

The people of North Carolina rebuilt their state quickly. By the 1880s, farm production equaled what it had been before the war. Tobacco and cotton crops led the growth. Industry also grew rapidly. Many new cotton mills opened. Tobacco-manufacturing and furniture-making also became large-scale industries. Industrialist Thomas Buchanan Duke built up the American Tobacco Company until it had eliminated most competition. Farmers left the farms for industrial jobs in the cities.

In 1898, the Democrats won control of the state legislature in a campaign based on racial hatred. They amended the state Constitution to deprive most blacks of voting rights. New laws required the racial segregation of schools, restaurants, railroad trains, streetcars, and other public facilities.

**The early 1900s.** In 1901, Governor Charles B. Aycock started a far-reaching program to improve North Carolina’s public education system. In 1915, the legislature created the State Highway Commission, which began the largest roadbuilding program in the state’s history. That program earned North Carolina the nickname of the “Good Roads State” during the 1920s.

The state’s industries developed at a tremendous rate during the early 1900s. By the late 1920s, North Carolina led the nation in the production of cotton textiles, tobacco products, and wooden furniture.

The Great Depression of the 1930s brought sudden drops in prices and wages. Businesses closed and banks failed. Workers lost their jobs and farmers lost their farms. The federal and state governments tried to fight the effects of the depression. The North Carolina government reduced local taxes and took control of all highways and public schools. Federal control of agricultural production raised farm prices and income. The state passed welfare measures, raised teachers’ salaries, and reduced working hours to help North Carolina out of the depression by the late 1930s.

**The mid-1900s.** During World War II (1939-1945), North Carolina mills supplied the armed forces with more textiles than any other state. Its mines supplied more than half the mica used in U.S. war production.

In the late 1940s, North Carolina built new hospitals and mental health facilities, and it paved many roads in rural areas. Two dams increased the state’s power output. Fontana Dam, at the edge of the Great Smoky Mountains, started operating in 1945, and Kerr Dam, near Henderson, went into operation in 1954.

North Carolina blacks began to gain greater rights during the mid-1900s. A key event occurred in 1954, when the Supreme Court of the United States ruled that compulsory school segregation was illegal. In 1960, four black students remained seated at a restricted lunch counter in Greensboro after they were refused service. Their action sparked a wave of sit-in demonstrations throughout the South. Such protests contributed to the passage of the Civil Rights Act of 1964, which banned the segregation of public facilities.

During the 1950s, North Carolina continued to shift from a rural, agricultural economy to an urban, industrial economy. The state worked to attract new industries by providing businesses with technical and engineering assistance and by reducing taxes on corporations. By 1956, three universities—Duke University at Durham, North Carolina State University at Raleigh, and the University of North Carolina at Chapel Hill—combined their research resources. They helped form the North Carolina Research Triangle Park, a research center that serves industry. The center opened in 1959.

In 1963, the legislature set up a system of community colleges and technical institutes. Also in 1963, the state adopted a single university plan for the University of North Carolina, beginning with campuses at Chapel Hill, Greensboro, and Raleigh. By 1972, the University of North Carolina had 16 campuses. These included the North Carolina School of the Arts, which had become the nation’s first state-supported school for the arts when it opened in Winston-Salem in 1965.

**The late 1900s.** In 1971, in a case involving a Charlotte school district, the Supreme Court of the United
North Carolina

States ruled that children could be bused to achieve racial integration. Most North Carolina school districts were integrated soon afterward. The Charlotte busing program became a model for the rest of the country.

The Republican Party increased its strength in the state in the late 1900’s. In 1972, James E. Holshouser, Jr., became the first Republican to be elected governor of North Carolina since 1896. Also in 1972, Jesse A. Helms became the first Republican candidate to be elected to the United States Senate from North Carolina since 1895.

The development of Research Triangle Park brought prosperity to Durham, Raleigh, Chapel Hill, and the surrounding area. In the late 1980’s and the 1990’s, many of North Carolina’s urban areas experienced growth in the finance and technology industries. However, employment in many traditional industries, including tobacco and textiles, declined. During the 1980’s and the 1990’s, North Carolina experienced growth in agricultural-related businesses, such as hog, poultry, and sweet potato production. The filmmaking industry also flourished. Population growth in the state’s urban areas increased demand for better schools, highways, health care facilities, and other government services.

Recent developments. In 1999, school busing was discontinued in the Charlotte school district. A federal judge ruled that forced integration was no longer necessary because all traces of intentional discrimination had disappeared.

In September 1999, North Carolina suffered one of the worst natural disasters in its history. Hurricane Floyd’s floodwaters left drowned livestock and flooded farms and towns all across the eastern part of the state. Officials estimated the damage costs of the storm to be billions of dollars.

**North Cascades National Park** is in northwestern Washington. The park's magnificent scenery includes mountain ridges, forested valleys, alpine lakes and meadows, waterfalls, and glaciers. Among the animals that live in the park are bears, cougars, deer, moose, mountain goats, and wolverines. The park also has magnificent cedar and fir forests. The park was established in 1968, along with the adjacent Lake Chelan National Recreation Area and Ross Lake National Recreation Area. For the area of North Cascades National Park, see National Park System table: National parks. For location, see Washington (political map).

Critically reviewed by the National Park Service

**North Central States** are the 12 states in the north-central part of the United States. They include Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin.

The western North Central States, which are sometimes called the Great Plains States, contain some of the richest farming land in the world. Corn and wheat fields cover the plains. The states on the eastern edge of the region are sometimes called the Lake States. These states are known for their great industrial centers, in addition to their farms.
North Dakota

North Dakota is a Midwestern state of the United States. It lies in the center of the North American continent. The geographic center of North America is near the town of Rugby. North Dakota is mainly a farm state. Its economy is based more heavily on farming than that of any other state except South Dakota. Many North Dakota factories process farm products or farm equipment. Many of the state's merchants also rely on agriculture. North Dakota has a larger percentage of agricultural workers than most other states. About 56 of every 100 North Dakotans live outside of metropolitan areas.

Farms and ranches cover nearly all North Dakota. They stretch from the flat Red River Valley in the east, across rolling plains, to the rugged Badlands in the west. The chief crop, wheat, is grown in every county. North Dakota harvests about three-fourths of the nation's flaxseed. It is also the top producer of sunflower seeds and barley in the country and a leader in the production of oats, pinto beans, rye, and sugar beets.

Soil is North Dakota's most precious resource. It is the base of the state's great agricultural wealth. But North Dakota also has enormous mineral resources. These mineral resources include 400 billion to 600 billion tons (360 billion to 540 billion metric tons) of lignite coal. In addition, North Dakota has large oil reserves. Petroleum was discovered in the state in 1951 and quickly became North Dakota's most valuable mineral resource.

Few white settlers came to the North Dakota region before the 1870's because railroads had not yet entered the area. During the early 1870's, the Northern Pacific Railroad began to push across the Dakota Territory. Large-scale farming also began during the 1870's. Eastern corporations and some families established huge wheat farms covering large areas of land in the Red River Valley. The farms made such enormous profits that they were called bonanza farms. White settlers, attracted by the success of the bonanza farms, flocked to North Dakota, rapidly increasing the territory's population. In 1870, North Dakota had 2,405 people. By 1890, the population had grown to 190,983.

North Dakota was named for the Sioux Indians who once lived in the territory. The Sioux called themselves Dako- ta or Lakota, meaning allies or friends. One of North Dakota's nicknames is the Peace Garden State. This nickname honors the International Peace Garden, which lies on the state's border with Manitoba. But North Dakota is most often called the Flickertail State, because of the many flickertail ground squirrels that live in central North Dakota. Bismarck is the capital of North Dakota, and Fargo is the largest city.
Interesting facts about North Dakota

About two-thirds of the lignite coal in the United States can be found throughout the western portion of North Dakota. The size of the resources is estimated at between 400 and 600 billion short tons (360 and 540 billion metric tons). This is considered one of the largest single concentrations of solid fuel in the world.

North and South Dakota were admitted to the Union simultaneously. On Nov. 2, 1889, President Benjamin Harrison signed the proclamation that made North and South Dakota states. He shuffled the states’ admission papers so that one state could not claim to have been admitted before the other. Today, the two are listed alphabetically, making North Dakota the 39th and South Dakota the 40th.

Petroleum is the most profitable mineral in North Dakota. Most of the petroleum is recovered from the thousands of wells located in the western part of the state.

An international golf course is based in Portal. Part of the course lies in the United States and part is in Canada. An international hole-in-one can be scored on the ninth hole. The tee for the ninth hole is in Canada, and the cup is in the United States. George Wegener scored the first international hole-in-one there in 1934.

The geographic center of North America is located near the town of Rugby in Pierce County.

Fargo is the largest city in North Dakota. It is one of only four cities in the state with a population of more than 25,000. The other three cities are Bismarck, Grand Forks, and Minot.
North Dakota in brief

Symbols of North Dakota
The state flag, adopted in 1911, bears a modified version of the coat of arms of the United States. On the state seal, adopted in 1889, a tree in an open field is surrounded by bundles of wheat, which represent agriculture. A plow, anvil, and sledge also symbolize farming. The bow and arrows and the Indian on horseback chasing a buffalo represent the Indian nations that thrived in the North Dakota region for hundreds of years.

General information
Statehood: Nov. 2, 1889, the 39th state.
Abbreviations: N. Dak. or N.D. (traditional); ND (postal).
State motto: Liberty and Union, Now and Forever, One and Inseparable.

Land and climate
Area: 70,704 sq. mi. (183,123 km²), including 1,710 sq. mi. (4,428 km²) of inland water.
Elevation: Highest—White Butte, 3,506 ft (1,069 m) above sea level. Lowest—750 ft (229 m) above sea level in Pembina County.
Record high temperature: 121 °F (49 °C) at Steele on July 6, 1936.
Record low temperature: −60 °F (−51 °C) at Parshall on Feb. 15, 1936.
Average July temperature: 70 °F (21 °C).
Average January temperature: 7 °F (−14 °C).
Average yearly precipitation: 17 in. (43 cm).

Important dates
The United States acquired southwestern North Dakota through the Louisiana Purchase.
The Dakota Territory was opened for homesteading.

1738 Pierre Gaultier de Varennes, Sieur de La Verendrye, made the first explorations in North Dakota.
1803
1818
1863
1863

The United States acquired northeastern North Dakota in a treaty with Britain.

For information about tourism, write to: Tourism Department, Liberty Memorial Building, 604 East Boulevard, Bismarck, ND 58505-0825. The Web site at www.ndtourism.com also provides information.

For Information on the economy, write to: Department of Economic Development and Finance, 1833 E. Bismarck Expressway, Bismarck, ND 58504-6708.

The state's official Web site at discovernd.com also provides a gateway to much information on North Dakota's economy, government, and history.

1889 - North Dakota became the 39th state on November 2.
1951 - Oil was discovered near Tioga.
1956 - Construction began on the Garrison Diversion Project to increase the state's water supply.
1968 - The first generator at Garrison Dam began to produce electric power.
1997 - Flooding along the Red River caused severe damage, especially in Grand Forks.
Population. The 2000 United States census reported that North Dakota had 642,200 people. The population had increased by less than 1 percent over the 1990 figure, 638,800. According to the 2000 census, North Dakota ranks 47th in population among the 50 states.

About 44 percent of the people of North Dakota live within one of the state's three metropolitan areas (see Metropolitan area). The Bismarck area is entirely in North Dakota, and the Fargo-Moorhead and Grand Forks areas extend into Minnesota. For the populations of these metropolitan areas, see the Index to the political map of North Dakota.

North Dakota has no large manufacturing industries to encourage the growth of big cities. Only 17 cities in the state have more than 2,500 people. Only four have more than 25,000 people. They are, in order of size, Fargo; Bismarck, the state capital; Grand Forks; and Minot. About a third of the state's people live in these four cities.

North Dakota's larger cities still serve their original function as centers of shipping, supply, and trade for the surrounding agricultural region. Most of the factories in North Dakota's cities are small. They manufacture, pack, and process food and food products.

White settlers began to pour into North Dakota by the thousands in the 1870's and 1880's. They were attracted by reports of the large profits made in wheat farming and the availability of free government land. Settlers came from states to the east and south and from Europe. The largest number from other nations came from Norway. They settled throughout the region. Germans from Russia settled in the south-central area, and Canadians moved into the northern Red River Valley. Today, the state's largest population groups are made up of people of German and Norwegian descent.

Schools. In 1818, Roman Catholic missionaries set up the first school in the North Dakota region, at Pembina in the northeast. They taught métis (people of mixed white and Indian ancestry) of the region and the children of Scottish and Irish settlers who came from Canada. The school closed in 1823, when Pembina was abandoned. In 1848, Father George Belcourt, a Catholic priest, reopened the school as an Indian mission.

In the early days, teachers traveled from village to village, teaching groups of children in homes. As the settlements grew, the colonists built schools and hired teachers. Railroad companies, anxious to attract settlers, helped by supplying building materials.

In 1862, the first legislature of the Dakota Territory passed "An Act for the Regulation and Support of Common (public) Schools." Between 1862 and statehood in 1889, the territory reorganized its educational system several times. The first state legislature created a fund for the support of all schools teaching the English language. Taxes now support the public schools in North Dakota.

The superintendent of public instruction administers the North Dakota public school system. He or she is elected to a four-year term. This official and a special staff make up the state Department of Public Instruction. Children must attend school from ages 7 through 15. The number of students and teachers in North Dakota, see Education (table).

Libraries and museums. Women's clubs did much to organize and improve North Dakota's early libraries. In 1897, a women's club opened the state's first public library at Grafton.

Today, North Dakota has numerous public libraries around the state. In 1898, the state Department of Public Instruction set up traveling libraries to serve the schools. In 1907, the state library commission (now the North Dakota State Library) was established to administer the traveling libraries and provide other services. North Dakota State University in Fargo and the University of North Dakota in Grand Forks have the largest libraries in the state. Both house large collections on North Dakota's history.

The State Historical Society in Bismarck operates a library with large collections relating to the state's history. The society also has a museum in Bismarck that includes exhibits dealing with the life of early North Dakota Indians, pioneer days, and natural history. The historical society operates museums at Fort Abercrombie, Camp Hancock, Fort Buford, Fort Pembina, Fort Totten, Whithorne Hill Battlefield, Chateau de Mores, and the former Governor's Mansion in Bismarck.

WORLD BOOK map, based on U.S. Census Bureau data.
North Dakota's crisp autumn days attract thousands of hunters to streams and lakes where migrating waterfowl pause on their way south. Hunters also shoot grouse, Hungarian partridges, pheasants, and other game birds. Vacationers catch catfish, perch, pike, trout, and other fishes. Favorite summer-resort areas include the Badlands region, including Theodore Roosevelt National Park; Devils Lake; and the Killdeer, Pembina, and Turtle Mountains.

During the summer, musicals are offered at Fort Totten, on an Indian reservation south of Devils Lake. Fort Totten has the nation's only preserved "cavalry square." Variety shows are offered in the Burning Hills Amphitheater near Medora, a picturesque old cow town that has been restored. The town is a popular tourist attraction.

Summer visitors to North Dakota also enjoy colorful Indian powwows conducted on various reservations in the state. Many tourists attend the exciting rodeos that are held in numerous communities throughout North Dakota.

Places to visit

Following are brief descriptions of some of North Dakota's many interesting places to visit:

**Bonanzaville, USA**, in West Fargo, is a preserved pioneer village. It has 40 buildings, including a church, a one-room schoolhouse, a general store, a log cabin, a town hall, a jail, a drugstore, a hotel and bar, a market, and a museum that features American Indian items.

**Château de Mores**, near Medora, was the home of a Frenchman, the Marquis de Mores, who founded Medora in 1883.

**International Peace Garden** is a park that lies partly in North Dakota and partly in Manitoba. It symbolizes the long friendship between the United States and Canada. See International Peace Garden.

**Lake Sakakawea**, the reservoir for Garrison Dam, is about 60 miles (97 kilometers) north of Bismarck. The site is popular for swimming, boating, fishing, camping, and picnicking.

**Lewis and Clark Interpretive Center**, at Washburn, offers displays and exhibits on Native Americans who befriended Lewis and Clark.

**Writing Rock**, near Grenora, is a large glacial boulder covered with Indian picture writing.

**National parklands**, Theodore Roosevelt National Park lies in the scenic Badlands. It was established in 1947 in memory of President Roosevelt, who operated two ranches in the area in the 1880's. The park is a wildlife sanctuary. The Knife River Indian Villages National Historic Site, near Stanton, includes the remains of five Hidatsa Indian villages that were occupied until 1845. The Fort Union Trading Post National Historic Site, which North Dakota shares with Montana, was a major fur trading post in the mid-1800's.

**State parks**, North Dakota has 18 state parks and campgrounds and many historic and military sites. Fort Abraham Lincoln State Park, near Mandan, is an important historic site. In 1876, Lieutenant Colonel George A. Custer set out from Fort Abraham Lincoln on the expedition that ended in the Battle of the Little Bighorn. Fort Totten, a state historic site on the Fort Totten Indian Reservation, includes a U.S. military post that dates from 1867. For information on the state parks of North Dakota write to Tourism Department, Liberty Memorial Building, Bismarck, ND 58505.
Annual events

January-June
North Dakota Winter Show in Valley City (March); Fort Seward Wagon Train in Jamestown (June); Old Time Fiddlers Contest at the International Peace Garden (June); Frontier Army Days at Fort Abraham Lincoln (June); Fort Union Rendezvous near Williston (June); Medora Musical in Medora (June through Labor Day); special theme events at Trollwood Park in Fargo (June through Labor Day).

July-December
Governor's Cup Walleye Fishing Tournament on Lake Sakakawea (July); Jaycee Rodeo Days in Mandan (July); North Dakota State Fair in Minot (July); Champion's Ride Rodeo in Sentinel Butte (August); Rough Rider Days in Dickinson (July); Pioneer Days at Bonanzaville, USA, in West Fargo (August); Folkfest in Bismarck (September); United Tribes Powwow in Bismarck (September); Norsk Hostefest in Minot (October); Threshing Bee in Makoti (October); Dickens Village Festival in Garrison (November-December).
Land regions. North Dakota has three major land regions: (1) the Red River Valley, (2) the Drift Prairie, and (3) the Great Plains. These regions rise in three broad steps from east to west.

The Red River Valley lies along the Minnesota border. This region is extremely flat. The valley is part of the bed of an ancient glacial lake, Lake Agassiz (see Lake Agassiz). The silt (soil particles) of the former lake bottom makes this valley one of the most fertile farming areas in the world. Livestock farms and fields of wheat and other crops cover most of the region. The valley is the most heavily populated part of North Dakota.

The Drift Prairie rises on the western border of the Red River Valley. An escarpment (steep slope) separates the two regions. The escarpment is steepest in the north in the Pembina Hills (sometimes called the Pembina Mountains), which tower several hundred feet or meters above the Red River Valley. Generally, the Drift Prairie rises gradually toward the west and southeast. Near the region's western border, the land is from 300 to 2,000 feet (91 to 610 meters) above the Red River Valley. The glaciers that crossed the Drift Prairie during the Pleistocene Epoch, which ended about 11,500 years ago, left rich deposits of earth materials called drift. The passage of glaciers also earned the area the name Glaciated Plains. Most of the region has rolling hills, and is cut by stream valleys. In the north, the Turtle Mountains rise about 550 feet (168 meters) above the surrounding plains. The Drift Prairie has many small lakes where thousands of wild ducks nest every year.

The Great Plains cover the southwestern half of North Dakota. This region is part of the immense highland that extends from northern Canada to southern Texas (see Great Plains). North Dakotans call the region the Missouri Plateau. The region begins at the Couteau Slope. The slope rises 300 to 400 feet (91 to 120 meters) above the Drift Prairie just east of the Missouri River. It crosses the state from northwest to southeast. The area is hilly, and is used for grazing cattle. It is also rich in mineral deposits.

A narrow band of lowlands called the Missouri Breaks follows the sweep of the Missouri River. The area south and west of the river is called the Slope. There, rough valleys and buttes (steep hills that stand alone) break up the flatness of the plains. Many small streams wind around the hills as they flow toward the larger rivers.

The Badlands of the Little Missouri River lie in the southwest. This strip of rough, beautiful land is 6 to 20 miles (10 to 32 kilometers) wide and about 190 miles (300 kilometers) long. The Badlands are a sandstone, shale, and clay valley in which wind and water have carved weird formations. Buttes, domes, pyramids, and cones colored with bands of browns, reds, grays, and yellow.

The Red River Valley is one of the most fertile farming areas in the world. It lies along the Red River of the North, which forms the North Dakota-Minnesota border.

The Red River Valley
—rise from the floor of the valley. One of the buttes, White Butte, is 3,506 feet (1,069 meters) above sea level, the highest point in North Dakota. In parts of the Badlands, the rocks contain lignite coal. Some coal beds have been burning for many years, turning the clay above them bright red and pink. This burned material, called scoria, is used for surfacing roads.

Rivers and lakes. The Missouri River drains about 60 percent of North Dakota, and the Red River of the North drains most of the rest of North Dakota. The great Missouri winds through the western part of the state. Its branches include the Cannonball, Heart, Knife, and Little Missouri rivers. The James River begins in central North Dakota and flows southward into South Dakota. Garrison Dam, 12,000 feet (3,658 meters) long, spans the Missouri near Riverdale. The waters above the dam form Lake Sakakawea. This lake is 178 miles (286 kilometers) long and an average of 3 1/2 miles (5.6 kilometers) wide. The dam helps control floods and provides water for irrigation and hydroelectric power.

The Badlands of North Dakota lie in the southwestern part of the state along the Little Missouri River. Wind and water have carved unusual formations out of sandstone, shale, and clay in this rugged area.

The Red River of the North and its branches flow northward through eastern North Dakota and empty into Lake Winnipeg in Canada. The largest branches include the Goose, Park, Pembina, and Sheyenne rivers. The Souris River drains a flat, fertile area in the north-central section. It flows southward from Saskatchewan, and then circles back north into Manitoba.

Numerous small lakes dot the Drift Prairie. Many lie in beds scooped out by the glaciers. Devils Lake, in the north-central part of the region, is the largest natural lake in the state. It has no outlet, and its water is salty. The lake has been shrinking, and the state plans to raise the water level.

Plant and animal life. Forests cover only about 1 percent of North Dakota. Trees that grow in the east include the ash, aspen, basswood, boxelder, elm, oak, and poplar. The largest stands of timber are in the Turtle Mountains and Pembina Hills and in the hills surrounding Devils Lake. Ash, cottonwood, elm, and willow trees grow along the Missouri River and its branches.

Lake Sakakawea was formed when engineers built Garrison Dam across the Missouri River. The lake is 178 miles (286 kilometers) long.
Average January temperatures

Winters can be bitterly cold. Temperatures are coldest in the northeast and warmest in the southwest.

In spring and summer, brilliantly colored flowers bloom. They include beard-tongues, black-eyed Susans, gaillardias, pasqueflowers, prairie mallows, red lilies, and wild prairie roses. chokecherries, highbush cranberries, and wild plums grow in many parts of North Dakota. Bluegrass thrives in the northeast, and buffalo and gama grasses thrive in the southwest.

White-tailed deer graze throughout North Dakota. Mule deer and pronghorns range the western plains. In the Badlands, prairie dogs live in scattered colonies called *dog towns*. Fur-bearing animals found in the state include badgers, beavers, bobcats, coyotes, foxes, lynxes, minks, muskrats, rabbits, raccoons, skunks, and weasels. Flickertail ground squirrels are commonly seen.

Every summer, ducks migrate to North Dakota to breed in the lakes, marshes, and grainfields. More waterfowl hatch in North Dakota than in any other state. Game birds include grouse, Hungarian partridges, and pheasants. Fish in the state’s waters include bass, carp, catfish, perch, trout, and walleye pike.

Climate. Summers in North Dakota are generally clear and pleasant. The sun shines more than 13 hours on each clear day from mid-May through July. Even the hottest days are seldom uncomfortable because the humidity is low. Winters can be severe. Winds that sweep across the plains make the cold bitter.

July temperatures average 67 °F (19 °C) in the northern part of North Dakota and 73 °F (23 °C) in the south. The state’s record high temperature was 121 °F (49 °C), at Steele on July 6, 1936. January temperatures average 3 °F (-16 °C) in the northeast part of the state and 14 °F (-10 °C) in the extreme southwest. The state’s lowest temperature, -60 °F (-51 °C), was recorded at Parshall on Feb. 15, 1936.

The southeast has the most precipitation—about 20 inches (51 centimeters) a year. Some western areas of the state receive only about 13 inches (33 centimeters). Most of the rain in North Dakota falls between April and September. Snowfall averages about 32 inches (81 centimeters) yearly.

Economy

The large output of such commodities as grain, beef cattle, and petroleum help make agriculture and mining more important in North Dakota than they are in most other states. However, services and manufacturing continue to grow in economic importance in the state.

Service industries account for the majority of North Dakota’s *gross state product*—the total value of goods and services produced annually. The strong agricultural base greatly benefits the service industries. For example, trains carry wheat to wholesale distributors in the state’s large cities. Trains are part of the transportation, communication, and utilities industry; and wholesale distributors are part of the wholesale and retail trade industry. Agriculture also benefits North Dakota’s manufacturing
industry. The state's leading manufactured products include farm machinery and processed foods.

Natural resources. North Dakota's greatest natural resources are its outstandingly fertile soil and its enormous mineral deposits.

Soil is North Dakota's most valuable resource. It is the basis of one of the state's major industries—agriculture. North Dakota's richest soil lies in the Red River Valley. This fertile black soil is free of stones and contains much organic matter (decayed plant and animal remains). Loamy and sandy soils lie on the Drift Prairie west of the Red River Valley. Shale and limestone make up most of the soil of the Great Plains region.

Minerals. North Dakota has large deposits of petroleum in the west. These deposits lie in the Williston Basin, which extends from North Dakota into northern South Dakota, eastern Montana, and southern Canada. In North Dakota, this oil field has been developed in about 17 western counties. McKenzie and Williams counties are the leading producers. Bowman County in the southwest and other oil-producing counties in the northwest have natural-gas wells.

North Dakota has large deposits of lignite coal. These deposits lie in the western part of the state. Sand and gravel are found throughout North Dakota. The southwest has great amounts of clay, ranging in quality from common brick to the finest pottery clay.

Service industries provide the largest portion of North Dakota's gross state product. Service industries are concentrated in the state's major urban areas.

Wholesale and retail trade form North Dakota's leading industry in terms of the gross state product. The wholesale trade of food products, mined products, and motor vehicles is important in North Dakota. Major types of retail businesses in the state include grocery stores, hardware stores, restaurants, and service stations. About a third of those employed in retail trade work in restaurants and bars. Several companies run telemarketing operations in rural areas of North Dakota.

Community, business, and personal services are the state's second-ranked service industry. This group employs more people than any other industry in North Dakota. This industry group is made up of a variety of businesses, including private health care, law firms, motels, and repair shops. Fargo, Grand Forks, and Bismarck have large medical centers. These cities also host operation centers for several major corporations.

Government services rank third among the service industries. These services include the operation of public schools, public hospitals, military bases, and Indian reservations. Public schools employ many people, as do U.S. Air Force bases near Grand Forks and Minot. The U.S. government administers several national parks and wildlife refuges in North Dakota.

Finance, insurance, and real estate ranks next among North Dakota's service industries. Real estate is important because of the large amounts of money involved in the purchase of buildings, farmland, and other property. Fargo is North Dakota's center of banking and insurance.

Transportation, communication, and utilities are more important in North Dakota than in most other states because North Dakota's small population is widely scattered. Farm products and mined products often must travel great distances to reach market. Trucks and railroads transport much of the state's farm and coal output. Pipelines transport petroleum and natural gas. Telephone companies are the major part of the communications sector. Utilities provide electric, gas, and water service. More information about transportation and communication can be found later in this section.

Agriculture accounts for a larger portion of the gross state product in North Dakota than in most other states. The state has about 31,000 farms and ranches. Crop and pastures cover about 85 percent of North Dakota's total land area.

Wheat brings in more income than any other farm product in North Dakota. Only Kansas grows more wheat than North Dakota. Wheat is grown throughout the state, but production in the northern areas is especially heavy. A small percentage of North Dakota's wheat is durum wheat—a hard form of wheat used to make spaghetti and other kinds of pasta. North Dakota farmers grow the majority of the nation's durum wheat.

North Dakota leads all other states in the production of barley and sunflower seeds. Farmers grow barley mainly in the eastern part of the state. Sunflowers are grown chiefly in the Drift Prairie region. North Dakota farmers grow the majority of the nation's flaxseed. Flaxseed is the source of linseed oil, which is used to make paint. North Dakota also ranks among the leading producers of canola seed, honey, navy beans, oats, pinto beans, rye, soybeans, and sugar beets.

Hay plays an important role in North Dakota agriculture. The central part of the state produces the most hay. The hay is used almost exclusively as feed for cattle.

Livestock and livestock products account for about a fourth of North Dakota's agricultural income. The raising of beef cattle is the most important type of livestock farming in North Dakota. The central and western plains of North Dakota provide good pasturage and winter feed for beef cattle. Milk ranks second in value among livestock products. Many of the dairy farms are in the south-central part of the state. North Dakota farmers raise hogs in the southeast and south-central areas of the state, where corn is plentiful. North Dakota ranks

among the leading states in honey production.

**Manufacturing.** Goods manufactured in North Dakota have a *value added by manufacture* of about $2.5 billion annually. Value added by manufacture represents the increase in value of raw materials after they become finished products.

Food processing is North Dakota's leading manufacturing activity in terms of value added by manufacture. The industry benefits greatly from the state's strong agricultural base. North Dakota's major food products include bread and pasta, frozen potato products, and oils from oilseeds. The state's dairy products include milk and cheddar cheese. Sugar beet refineries operate in Drayton, Grand Forks, Hillsboro, and Wahpeton. The state's meat products include steaks and sausages.

The production of machinery ranks second among the manufacturing activities of North Dakota in terms of value added by manufacture. The Bobcat Company, a leading manufacturer of construction machinery, is headquartered in West Fargo and has plants in Bismarck and Gwinner. Bismarck, Minot, Wahpeton, and many other cities manufacture farm machinery.

Other products manufactured in North Dakota include fabricated metal products, petroleum products, printed materials, transportation equipment, and wood products. Structural metals and hand tools are important fabricated metal products made in the state. Mandan has a large oil refinery. Newspapers are the leading kind of printed material produced in the state. Aircraft parts are made in Jamestown. Important wood products include cabinets, counter tops, and furniture.

**Mining.** Petroleum is North Dakota's leading mined product. Oil fields lie in the western part of the state. The most productive field is in McKenzie County. This field is part of the great Williston Basin deposits.

Coal and natural gas are also important mined products in North Dakota. Beds of lignite coal lie under almost all of the western part of the state. McLean, Mercer, and Oliver counties in west-central North Dakota provide most of the coal. All of the state's coal comes from surface mines. The only major natural gas field lies in the southwest corner of the state. Natural gas is ob-

**Economy of North Dakota**

This map shows the economy of land in North Dakota and where the leading farm and mineral products are produced. The state's major urban areas are shown in red.

- Mostly cropland
- Grazing land mixed with cropland
- Shrubland mixed with grassland
- Woodland
- Manufacturing center
- Mineral deposit

WORLD BOOK map
tained as a by-product of oil and coal processing.

Among North Dakota's other mined products, sand and gravel provide the most income. Several areas of the state produce sand and gravel, which are used mainly in road construction. North Dakota's other mined products include clays and salt.

Electric power. Steam plants that burn lignite coal generate over 90 percent of North Dakota's electric power. Most of the rest of the state's electric power is produced by the hydroelectric project at Garrison Dam. Major coal-burning power plants are located at Beulah, Center, Mandan, Stanton, and Underwood. More than half of the electric power generated in North Dakota is exported by high-voltage transmission lines to other Midwestern states, chiefly Minnesota and Nebraska.

Transportation. North Dakota is a large state with a relatively small population. In addition, it is located far from the nation's large population centers. Thus, the state's transportation system is very important. The first railroad in North Dakota, the Northern Pacific, reached Fargo in 1872 and Bismarck in 1873. By 1881, the railroad line ran to the Montana border. Until a bridge was built, trains crossed the Missouri River at Bismarck on a ferry in summer and on tracks over the ice in winter.

By 1881, the Great Northern Railway had established a route between Fargo and Grand Forks. The railway built a line westward through Minot and Williston to the Montana border by 1887. Today, two rail lines provide freight service for North Dakota. In addition, passenger trains serve several North Dakota cities.

North Dakota has about 87,000 miles (139,000 kilometers) of roads and highways. The state's busiest commercial airport is at Fargo.

Communication. North Dakota's first newspaper, the Frontier Scout, was published in Fort Union in 1864. In 1873, Colonel Clement A. Lounsberry founded the Bismarck Tribune, the oldest newspaper still published in North Dakota. In 1876, Lounsberry wrote the first story of the Battle of the Little Bighorn. In this famous battle, Indians killed Lieutenant Colonel George A. Custer and all the troops under his immediate command. To write the story, Lounsberry used notes found in the buckskin pouch of Mark Kellogg, a reporter who was killed in the battle.

The largest daily newspapers in North Dakota include the Bismarck Tribune, The Fargo Forum, The Grand Fork Herald, and The Minot Daily News. The state's publishers print about 100 newspapers, of which about 10 are dailies. In addition, North Dakota publishers issue about 25 periodicals.

The first radio station in North Dakota, WDAY, started broadcasting in Fargo in 1922. The state's first television station, KCJB (now KXMC-TV), began operating in 1953 in Minot. North Dakota has about 75 radio stations and about 25 television stations. Cable TV systems and Internet providers serve several North Dakota communities.

Government

Constitution. North Dakota is governed under its original Constitution, adopted in 1889. An amendment (change) to the Constitution may be proposed in the state legislature. The proposed amendment must be approved by a majority of each house of the legislature. Then a majority of citizens voting on the proposal must approve it. The people may also sign a petition (formal request) proposing an amendment. After 4 percent of the people have signed the petition, the proposal is put on a statewide ballot. The proposal becomes law if a majority of voters approve it.

Executive. The governor of North Dakota is elected to a four-year term. The governor may serve an unlimited number of terms.

The lieutenant governor, attorney general, secretary of state, treasurer, auditor, and superintendent of public instruction are also elected to four-year terms. All of these officials may serve an unlimited number of terms. The people of North Dakota also elect three public-service commissioners, and one commissioner each of agriculture, of insurance, and of taxation.

The governor, attorney general, and commissioner of agriculture make up the state Industrial Commission. This commission regulates the North Dakota oil industry. In addition, it oversees the operation of the Bank of North Dakota in Bismarck and of the North Dakota Mill and Elevator in Grand Forks, both of which are state-owned.

Legislature of North Dakota, which is called the Legislative Assembly, has a 49-member Senate and a 98-member House of Representatives. Voters in each of the state's 49 legislative districts elect one senator and two representatives. Senators serve four-year terms, and representatives serve four-year terms.

The Assembly holds its regular session in odd-numbered years, beginning usually on the first Tuesday after the first Monday in January. Regular sessions of the Assembly are limited to 80 legislative, or working, days. The governor may also call special sessions.

Courts of North Dakota are headed by the state Supreme Court. The Supreme Court has five justices, all elected to 10-year terms. The people of North Dakota's seven judicial districts elect a total of 43 district court judges to six-year terms. The Supreme Court and district court judges elect a chief justice of the Supreme Court to a five-year term. All North Dakota judges are elected on a "no party" ballot—the ballot has no political party labels.

Local government. North Dakota has 53 counties. Each county is governed by a board of commissioners of three to five members elected to four-year terms. North Dakota has 361 incorporated cities. The 1967 legislature classed all cities and towns in North Dakota as cities. The cities are organized under mayor-council, city-manager, or commission government.

Revenue. Taxes bring in nearly half of the state government's general revenue (income). Most of the remaining revenue comes from federal grants and charges for government services. The largest sources of North Dakota's tax revenue are a general sales tax, a personal income tax, and a severance tax on petroleum extraction. Other important tax revenue sources in the state include taxes on corporate profits, motor fuels, and motor vehicle licenses.
The North Dakota House of Representatives meets in the house chambers in the State Capitol, located in Bismarck. Each of the House’s members is elected to serve a two-year term.

Politics. Throughout most of its history, North Dakota has strongly favored the Republican Party. But the Democrats gained strength in the mid-1900’s. The Nonpartisan League, a political organization of farmers, was founded in North Dakota in 1915. During its early years, the league often controlled the Republican Party. In 1956, however, the league joined with the state Democratic Party. This new, strong political force helped to elect Democrats. For example, in 1958, North Dakotans elected the state’s first Democrat to the U.S. House of Representatives. This was Quentin N. Burdick. Burdick was elected to the U.S. Senate in 1960. He served as a U.S. senator until his death in 1992.

In 1889, the people elected a Republican as their first governor. For the next 70 years, Republicans held the office of governor most of the time. But since 1961, Democrats have held the office of governor of North Dakota much longer than Republicans have.

North Dakotans have voted for Republican candidates in about four of every five presidential elections. For North Dakota’s electoral votes and voting record in presidential elections, see Electoral College (table).

History

Indian days. Six groups of Indians lived in North Dakota when white explorers and fur traders first arrived. The Mandan, Hidatsa, and Arikara Indians lived in permanent earthen lodges along the Missouri River. They were farmers but also hunted. The Chippewa resided and hunted in the northeast. The Yankton Sioux lived in the James and Sheyenne river valleys, where they hunted. The largest and most powerful tribe, the Lakota or Teton Sioux, lived in the southwest and were hunters. Led by the great chiefs Sitting Bull and Gall, the Lakota Sioux fiercely resisted the United States Army.

Exploration and early settlement. In 1682, René-Robert Cavelier, Sieur de La Salle, claimed for France all the land drained by the Mississippi River system. This territory included the southwestern half of present-day North Dakota, because the Missouri River—which drains this area—flows into the Mississippi. France also claimed the vast area south of Hudson Bay, which included the northeastern half of North Dakota. In 1713, France gave all this Hudson Bay territory to Britain.

North Dakota was first explored by a French Canadian, Pierre Gaultier de Varennes, Sieur de La Vérendrye. He set out from Canada in 1738 and reached the Mandan Indian villages near present-day Bismarck.

In 1762, France gave its land west of the Mississippi to Spain. Spain returned it to France in 1800. In 1803, the United States bought this region, called Louisiana, from France (see Louisiana Purchase).

In 1804, President Jefferson sent Meriwether Lewis and William Clark to explore the Louisiana Territory and to blaze a trail to the Pacific Ocean. They reached central North Dakota in October 1804, and built Fort Mandan on the east bank of the Missouri River, across from present-day Stanton. The explorers stayed at Fort Mandan.
until April 1805. They passed through North Dakota again in 1806 on their return from the Pacific.

In 1812, Scottish and Irish families from Canada made a permanent settlement in North Dakota, in Pembina. In 1818, the United States obtained northeastern North Dakota by a treaty with Britain. All of present-day North Dakota then became U.S. territory. The 1818 treaty also set the United States-Canadian border at the 49th parallel. Some of the Pembina settlers moved north, to be sure they were on British territory. The rest left in 1823, when a survey confirmed that Pembina was actually located in the United States. A number of métis (people of mixed white and Indian descent) remained in the region after the settlers left.

Territorial days. Congress created the Dakota Territory in 1861. President Abraham Lincoln appointed William Jayne as governor. The territory included the present states of North and South Dakota and much of Montana and Wyoming. The first legislature met in Yankton (now in South Dakota) in 1862.

In 1863, the territory was opened for homesteading. Settlers were given free land if they lived on it and improved it. But the territory developed slowly. Transportation was poor, and the settlers feared the Indians. In 1862, Sioux Indians killed hundreds of settlers in an uprising in Minnesota. Some of the Indians then fled to the Dakota Territory. The U.S. government sent troops into the territory to punish the Indians who had taken part in the Minnesota uprising. Several battles were fought as the soldiers pursued the Indians across the territory.

The federal government signed several treaties with the Indians in the Dakota Territory, giving them land on reservations. But the whites often broke the treaties, causing more Indian uprisings. Peace came in 1881, when the great Sioux leader Sitting Bull voluntarily surrendered to U.S. troops. See Indian wars (The Sioux wars); Sitting Bull.

Large-scale farming began about 1875, when eastern corporations and some families established huge wheat farms. Most of the farms were in the Red River Valley and ranged from 3,000 to 65,000 acres (1,200 to 26,300 hectares). The farms earned such tremendous profits they became known as bonanza farms. The farmers used machinery and orderly methods of planting, harvesting, and marketing. This was possible because only one crop — wheat — was raised. In time, other crops were introduced on the bonanza farms. As the bonanza farms developed, cattle companies from the southern plains moved into the Badlands. The future President Theodore Roosevelt was among those who helped open up the land along the Little Missouri River. Most of the bonanza farms were divided into smaller lots and sold to newcomers because low wheat prices in the 1890s made them unprofitable.

Statehood. During the 1870s, the people began to ask Congress to divide the Dakota Territory into two parts. The population centers had developed in far corners of the territory — in the northeast and the southeast. North-south travel between these two centers was difficult because the railroads had laid their tracks in an east-west direction. The two groups of settlers had little in common and wanted their own governments.

In February 1889, Congress established the present boundary between North Dakota and South Dakota. It also passed an enabling act, allowing the two regions to set up the machinery to become states (see Enabling Act). On Nov. 2, 1889, North Dakota became the 39th state, and South Dakota the 40th state. John Miller, a Republican, became North Dakota's first governor.

The early 1900s. North Dakota's population increased rapidly following statehood. The state had 190,983 people in 1890. In 1910, it had 577,056 people. Farming also grew rapidly. However, the farmers disliked having to deal with banks, grain companies, and railroad interests in Minnesota. In addition, they disliked the power that these out-of-state businesses held in North Dakota politics.

In 1915, the Nonpartisan League was founded in North Dakota. This organization supported the farmers. It called for state ownership of grain elevators, flour mills, packing houses, and cold-storage plants. It also wanted banks in farming areas that would grant loans at cost. Thousands of farmers joined the league.

In 1916, a league-supported candidate, Republican
Historic North Dakota

Pierre Gaultier de Varennes, Sieur de La Vérendrye, was the first white person to explore the North Dakota region. In 1738, he reached the Mandan Indian villages near present-day Bismarck while searching for a route to the Pacific Ocean.

Cattle ranching began in North Dakota in the late 1800's. The vast western range lands became a grazing area for cattle driven from Texas. Famous ranches included one owned by Theodore Roosevelt.

The petroleum industry in North Dakota began in 1951 when oil was discovered near Tioga. Petroleum became the state's most valuable mineral.

The Northern Pacific Railroad built a line to Fargo by 1872 and reached westward as far as Bismarck by 1873. Railroad building brought a rush of settlers to the region, and farming prospered in eastern North Dakota.

Garrison Dam, on the Missouri River north of Bismarck, began producing hydroelectric power in 1956. The dam ranks among the nation's largest earth-fill dams.

Important dates in North Dakota

1682 René-Robert Cavelier, Sieur de La Salle, claimed for France all the land drained by the Mississippi River. This land included southwestern North Dakota.

1738 Pierre Gaultier de Varennes, Sieur de La Vérendrye, made the first European explorations in North Dakota.

1803 The United States acquired southwestern North Dakota through the Louisiana Purchase.

1804-1806 Meriwether Lewis and William Clark passed through North Dakota on their expedition to and from the Pacific Ocean.

1812 Scottish and Irish settlers made the first attempt at permanent European settlement in North Dakota, at Pembina.

1818 The United States acquired northeastern North Dakota by a treaty with Britain.

1861 Congress created the Dakota Territory.

1863 The Dakota Territory was opened to settlers for homesteading.

c. 1875 The era of bonanza farming began.

1889 North Dakota became the 39th state on November 2.

1915 The Nonpartisan League was founded.

1951 Oil was discovered near Tioga.

1956 The first generator at Garrison Dam began to produce electric power. The dam was completed in 1960.

1968 Construction began on the Garrison Diversion Project to increase the state's water supply.

1996 Congress approved a modified version of the Garrison Diversion Project.

1989 North Dakota celebrated its statehood centennial.

1997 Spring flooding produced enormous damage in the Red River Valley, especially in the city of Grand Forks.

WORLD BOOK illustrations by Kevin Chadwick
Lynn J. Frazier, was elected governor of North Dakota. During Frazier's administrations, from 1917 to 1921, the state legislature passed a number of progressive laws. Rural schools received more funds. Taxes on farm improvements were lowered. An Industrial Commission was set up to manage businesses begun by the state. In 1919, the Bank of North Dakota was established in Bismarck. In 1922, the North Dakota Mill and Elevator in Grand Forks began operating. These state-owned businesses are still in operation.

The Great Depression struck the entire nation during the 1930's. In addition, North Dakota suffered a severe drought. The state's farm production plunged sharply, and its population also began to decline. The population had reached a peak of 680,845 in 1930.

During the 1930's, the state and federal governments took many steps to help North Dakota farmers. In 1937, the State Water Conservation Commission was created. Since that time, state, federal, and private agencies have set up various projects to provide irrigation and prevent erosion of the soil. These agencies also encourage dry farming (farming methods that make the most of limited rain).

The mid-1900's. North Dakota's economy recovered during World War II (1939-1945). Farmers broke all their production records in supplying much food for the armed forces. But in the late 1940's, farm prices sagged as a result of farm surpluses throughout the country. The increased use of machines on farms left large numbers of farmworkers unemployed. Many found jobs in towns and cities, and North Dakota's urban population increased. But thousands could not find jobs in the state and left in search of opportunities elsewhere.

Construction of the great Garrison Dam near Riverdale began in 1946. This dam provides flood control, hydroelectric power, and water for irrigation. The dam was completed in 1960. Two lignite-burning power plants near Stanton have also helped the economy.

Oil was discovered near Tioga in 1951 and became the state's most valuable mineral. By 1970, oil wells were operating in 14 counties of western North Dakota.

In 1957, North Dakota established an Economic Development Commission that works to attract industry to the state. More than 80 North Dakota communities now have their own development commissions. Largely as a result of these commissions, the state's rate of industrial growth ranked among the highest in the country from 1958 to 1969. The U.S. Air Force helped the state's economy during the 1960's. It built bases near Grand Forks and Minot.

The Garrison Diversion Project was started in 1968. It included the construction of a canal system to bring water for irrigation from the Missouri River to large sections of North Dakota farmland. It also included plans to supply water to a number of cities and towns.

Late 1900's. During the early 1970's, growing concerns about the effect the Garrison Diversion Project would have on the environment slowed construction. For example, the Canadian government protested because the project, which called for the transfer of U.S. water into Canada, could have introduced pollutants into Canadian waters. In 1986, the U.S. Congress passed an act that modified the project in response to some of these concerns about the environment. During the 1970's, North Dakota increased coal, oil, and natural gas production as a step toward broadening its economy.

Farm production remained high during the 1980's and 1990's. But state leaders, fearing a possible crop failure or a disastrous drop in farm prices, continued to seek new industry for North Dakota. The number of nonagricultural jobs was increasing, but not enough to keep up with the decline in farm jobs. The task of attracting new industry to the state remained difficult because North Dakota lies so far from the nation's largest population centers.

In 1997, North Dakota suffered heavy snowfalls that produced damaging spring floods. Flooding of the Red River of the North forced almost 50 percent of the people of Grand Forks to evacuate. Over 70 percent of the buildings in Grand Forks experienced water damage.

Recent developments. In 2000, Congress replaced the Garrison Diversion Project with a new act called the Dakota Water Resources Act. The new law authorized more than $600 million for water supply and recreation projects in the state.  Douglas C. Munski and D. Jerome Tweton

Questions
Why did few settlers come to the Dakota Territory in the early days even though they were given free land?
What mineral was discovered in North Dakota in 1951?
Why is soil the most precious resource of North Dakota?
How did trains cross the Missouri River at Bismarck before a bridge was built over the river?
North Dakota is the nation's leading producer of what crops?
What were the bonanza farms?
Why did the settlers of the Dakota Territory want the territory divided into two parts?
Where in the state have coal beds been burning for many years?
How is the burned material used?
Why does North Dakota need more industry?

North Dakota, University of, is a state-supported liberal arts institution in Grand Forks, North Dakota. It has colleges of aerospace sciences, arts and sciences, business and public administration, education, engineering and mines, fine arts, human resources development, and nursing. It also has a graduate school; schools of law and medicine; and a division of continuing education. A leading coal research facility is also located at the university. The university grants bachelor's, master's, and doctor's degrees. It was founded in 1883.

North Dakota State University is a state-controlled coeducational school at Fargo, North Dakota. The university has undergraduate colleges of agriculture; education; engineering and architecture; home economics; humanities and social sciences; pharmacy; science and mathematics; university studies; and a school of education. North Dakota State also has a graduate school. The university grants bachelor's, master's, and doctor's degrees. The university includes the North Dakota Agricultural Experiment Station and the Cooperative Agricultural Extension. The school was founded in 1890 as the North Dakota Agricultural College. It took its present name in 1960.

North Korea. See Korea.

North Platte (pop. 23,878) is the center of a farming and cattle-raising region in western Nebraska. For location, see Nebraska (political map). North Platte plays an important role in the U.S. railroad network. Most transcontinental traffic on the Union Pacific Railroad passes through the city's Bailey Yard, a computer-controlled facility for sorting freight cars into trains. Besides railroading, major economic activities in the city include retail trade, tourism, and processing agricultural products. The famous frontiersman Buffalo Bill built a home near North Platte in 1886. The home is now the site of the Buffalo Bill Ranch State Historical Park. The city also hosts a statewide celebration, Nebraskaland Days, in June each year. The celebration includes a rodeo.
The city was first settled in 1866. It began as a construction camp for workers who were building the Union Pacific Railroad.

North Platte is the seat of Lincoln County. The city has a mayor-council form of government.

Laura Johnston

North Pole is a term used for several invisible surface points located in the Arctic region. The best known is the north geographic pole. But other important north poles include the instantaneous north pole, the north pole of balance, the north magnetic pole, and the geomagnetic north pole.

The north geographic pole lies near the center of the Arctic Ocean where all the earth's lines of longitude meet. American explorer Robert E. Peary led the first expedition usually credited with reaching this pole. The expedition included Matthew Henson, who was Peary's assistant, and four Inuit (formerly called Eskimos). They made the trip by dog team in 1909. American explorers Richard E. Byrd and Floyd Bennett are credited with reaching the pole by airplane in 1926, though recent evidence indicates they might not have succeeded. In 1958, the U.S.S. Nautilus became the first submarine to pass under the Arctic ice to the pole. In 1978, Naomi Uemura of Japan became the first person to reach the pole alone. He traveled by dog sled.

The instantaneous north pole lies at the point where the earth's axis (an imaginary line through the earth) meets the surface. The earth wobbles slowly as it turns around its axis, causing the instantaneous north pole to move. This pole takes about 14 months to move clockwise around an irregular path that is called the Chandler Circle. The diameter of this path varies from less than 1 foot (30 centimeters) to about 70 feet (21 meters).

The north pole of balance lies at the center of the Chandler Circle. Its position locates the north geographic pole. Each year since 1900, the north pole of balance has moved about 6 inches (15 centimeters) toward North America. This motion has caused tiny changes in the latitude and longitude of points around the earth.

The north magnetic pole is the farthest point on the earth in the direction of magnetic north. This pole can move many miles or kilometers in a few years. Today, the north magnetic pole is located near Elles Ringnes Island in northern Canada.

The geomagnetic north pole lies near Etah, Greenland, north of the town of Thule. In the upper atmosphere, the earth's magnetic field points down toward this point.

William C. Mahaney

North Sea is a wide arm of the Atlantic Ocean that lies between the island of Great Britain and the mainland of Europe. Seven nations—the United Kingdom, Norway, Denmark, Germany, the Netherlands, Belgium, and France—border the sea. The North Sea is a major trade
and transportation route. It is also an important source of petroleum, natural gas, and fish.

The North Sea covers 218,178 square miles (565,078 square kilometers). It extends almost 600 miles (960 kilometers) from north to south and about 360 miles (580 kilometers) from west to east. It has an average depth of 100 feet (30 meters) in the south and 400 feet (120 meters) in the north. The Strait of Dover and the English Channel connect the North Sea with the Atlantic Ocean. Skagerrak, an arm of the sea, links it with the Strait of Kattegat and the Baltic Sea. The Kiel Canal also connects the North and the Baltic seas.

Weather conditions in the North Sea are unpredictable, especially in winter. Winds of up to 100 miles (160 kilometers) an hour and severe storms sometimes occur, making navigation extremely dangerous.

In the 1960's, vast amounts of petroleum and natural gas were found under the North Sea. Today, the United Kingdom and Norway get large quantities of petroleum from the area. Natural gas is piped ashore to the United Kingdom and Germany.

The North Sea's fishing grounds rank among the richest in the world. Fish caught in the area include cod, haddock, herring, mackerel, pilchard, plaice, sole, and whiting. The sea also provides many kinds of shellfish.

The North Sea is one of the world's most important waterways for commercial activity. Its many major ports include London, England; Hamburg, Germany; Amsterdam and Rotterdam, the Netherlands; Antwerp, Belgium; and Dunkerque, France.

The North Sea has been used for trade and transportation since ancient times. Its position made it important during World War I (1914-1918) and World War II (1939-1945). During World War I, the United Kingdom controlled the North Sea and prevented the German Navy from using it as a route to the Atlantic Ocean. During World War II, Germany controlled the part of the sea between Norway and France. But the United Kingdom controlled the English Channel and the northern approach to the sea, allowing Allied ships to use the waterway.

D. Ian Scargill

**North-South Ministerial Council** is a political body that addresses matters of concern to the entire Island of Ireland. It brings together government representatives from the independent Republic of Ireland in the south and from Northern Ireland, which is part of the United Kingdom. The council deals with issues in such areas as agriculture, education, the environment, and health. Its decisions are subject to the approval of the Irish Parliament and the Northern Ireland Assembly, an elected body that has jurisdiction over most local affairs.

The North-South Ministerial Council was established by the 1998 Northern Ireland political settlement. This agreement aimed at ending the violence between Irish nationalists and unionists over control of Northern Ireland. Through the years, the nationalists have wanted Northern Ireland to become part of the Republic of Ireland, but the unionists have favored keeping Northern Ireland part of the United Kingdom. The council meets several times a year. For example, it gives the nationalists an all-island institution. It also provides the unionists with a way to cooperate with the Republic of Ireland without unification. Brendan O'Leary

See also **Northern Ireland (History).**

**North Star** is a readily visible star that appears to be almost directly above the North Pole. The term *polestar* is sometimes used for North Star. The North Star is presently Polaris, the brightest star in the constellation Ursa Minor. Polaris is within one degree of the place where the northern extension of the earth's axis pierces the sky. Because of its position, Polaris appears stationary, while other stars seem to revolve around the earth's axis as the earth rotates. As a result, Polaris has served as a guide for navigators through the centuries. Polaris is a star of the second magnitude. The brighter a star is, the lower is its magnitude (see Star [Brightness of stars]).

Polaris will not always be the North Star because the earth's axis will not always point toward Polaris. The earth's rotational axis changes direction in a circular motion called *precession.* Each end of the axis traces out a fictitious circle in the sky. One complete trip around the circle takes about 26,000 years. Thus, the brighter stars on or near the precessional circle above the earth's North Pole each become the North Star for a certain period. For example, in about 12,000 years, the earth's axis will point north to a spot near Vega in the constellation Lyra. In about 22,000 years, Thuban in the constellation Draco will become the North Star. About 26,000 years

---

![The North Sea](https://example.com/north-sea.jpg)

The North Sea contains vast deposits of natural gas and petroleum. These reserves were discovered during the 1960's and belong mainly to the United Kingdom and Norway. They have become a major energy source for western Europe. This offshore oil rig is pumping petroleum from beneath the sea.
from now, Polaris will return to its present location relative to the earth's axis, and will be the North Star.

Summer Starfield

North Warning System is a long-range radar network built to provide the United States and Canada with warning of an air attack from the north. It was completed in 1994. The system extends from northwest Alaska across northern Canada and down the coast of Labrador. It consists of 54 radar stations. NORAD, a U.S.-Canadian military alliance, controls the North Warning System (see NORAD).

In 1985, the United States and Canada agreed to improve surveillance by replacing the DEW (Distant Early Warning) line's aging radars and building additional radars. The improved system was renamed the North Warning System. The North Warning System replaced the DEW line after that system was deactivated in 1993.

Critically reviewed by NORAD

North West Company was a Canadian fur-trading company that became the main competition of the powerful Hudson's Bay Company during the late 1700's. Adventurous North West Company traders explored, mapped, and helped open up the little-known regions of northern and western Canada.

The company began to take shape in the 1770's, when several Montreal fur merchants started to combine their operations. The association collapsed during the early 1780's but was reestablished and adopted the name North West Company in 1784. Members of the company became known as Nor'Westers.

At first, the Nor'Westers competed successfully with the Hudson's Bay Company and with John Jacob Astor's Pacific Fur Company. North West Company traders found new sources of pelts while exploring the Far West. Notable Nor'Westers included Alexander Mackenzie and David Thompson. Mackenzie traveled to the Arctic Ocean in 1789 and to the Pacific Ocean in 1793.

Thompson explored and mapped the Columbia River area between 1807 and 1812. However, competition with the Hudson's Bay Company became increasingly difficult. In 1821, the North West Company faced severe financial problems and united with the Hudson's Bay Company.

Cornelius J. Jaenen

North-West Mounted Police. See Royal Canadian Mounted Police.

North West Rebellion was a conflict that arose in 1885 between the métis (people of mixed white and Indian ancestry) and the Canadian government in what is now Saskatchewan. It resulted from métis fears that government plans to encourage new farming settlements in the northwest would threaten their communities.
The métis had opposed the government in the Red River Rebellion in 1869 and 1870, in what is now the Canadian province of Manitoba. That conflict also had involved métis fears about the effects of white settlement on their lands. The métis demanded, and obtained, guarantees that the Canadian government would protect their property, cultural, religious, and language rights. The guarantees, however, proved too weak. As a result, the métis retreated west and established new communities in the valleys of the North and South Saskatchewan rivers. There, the métis laid out their small farms in the traditional French river lot pattern, in long strips bordering the rivers.

By the early 1880's, the métis became concerned about the effects of the nearly completed transcontinental railroad and the government's plans for white settlement in Saskatchewan. The government wanted the land divided into square lots, and it refused to approve métis claims for new lots laid out in riverfront strips.

The métis again called on Louis Riel, the leader of their earlier protest in Manitoba. In March 1885, Riel established a temporary métis government to negotiate with the Canadian government. The Canadian government regarded this as an act of treason. All possibility of negotiation ended when the métis and North-West Mounted Police fought near Duck Lake on March 26, 1885. People on both sides were killed. In addition, scattered fighting broke out between some Cree Indians and settlers.

Canada's government sent a military force to Saskatchewan. These troops, joined by the North-West Mounted Police and local volunteers, moved against the métis at Batoche. The métis, seriously outnumbered and poorly equipped, were defeated at Batoche in May 1885. Gabriel Dumont, their military leader, escaped to the United States. Riel was arrested, tried for treason, and hanged in Regina in November 1885.

After the rebellion, people in the northwest gained representation in the Canadian Parliament. Many French-speaking Canadians sympathized with the métis, and the rebellion led to increased tension between French- and English-speaking Canadians. The rebellion accomplished little for the métis.

Northcliffe, Viscount (1865-1922), a famous English journalist and publisher, pioneered in the use of comics, special features, religious news, and tabloid newspapers. He also played an important part in the formation in 1916 of the Coalition Cabinet led by David Lloyd George. Northcliffe owned the Amalgamated Press, a large magazine publishing house, and the London Evening News, the Daily Mail, the Daily Mirror, and The Times. He was born in County Dublin, Ireland. His given and family name was Alfred Charles William Harmsworth. Joseph P. McKerns

Northeast Passage. See Arctic Ocean.

Norther is a cold winter wind that sweeps over the southern United States, the Gulf of Mexico, and the east coast of Central America, destroying crops and wrecking ships. The northerns occur most frequently between October and April. Nortners often cause the temperature to rapidly drop as much as 30 to 50 Fahrenheit degrees (17 to 28 Celsius degrees). The wind usually blows over regions that border the western part of the Gulf of Mexico. Sometimes the wind reaches as far south as Panama. Occasionally, a norther starts as far north as Canada and extends over the entire Mississippi Valley. Scientists can predict a norther about 24 hours in advance. In Central America, this wind is called el norte. Richard A. Dirks

Northern harrier, sometimes called marsh hawk, is the only species of harrier that lives in North America. It also lives in Europe, where it is called a hen harrier, and in northern and central Asia. A harrier is a type of hawk.

Northern harriers have long wings, tails, and legs. They measure 17 to 24 inches (43 to 61 centimeters) long with a wingspread of 40 to 54 inches (101 to 137 centimeters). The females grow slightly larger than the males. Adult male northern harriers are mostly light-gray above and white below. Adult females have brown coloring above with dark streaking underneath. The young birds resemble the females but have less streaking below.

Like owls, northern harriers have a saucer-shaped ruff of feathers around the eyes. This ruff, called a facial disk, reflects sound to the harrier's ear openings. The northern harrier usually hunts small birds and mammals. Its facial disk helps it detect prey by sound. The bird then swoops down and kills its victim.

Northern harriers nest on the ground. The males are the only North American birds of prey that typically mate with more than one female during the same period of time. Females usually lay from 4 to 6 eggs. Richard D. Brown

Scientific classification. The northern harrier belongs to the family Accipitridae. Its scientific name is Circus cyaneus.

See also Harrier; Hawk.

Northern Hemisphere. See Hemisphere.
Northern Ireland is the smallest of the four political divisions that make up the United Kingdom of Great Britain and Northern Ireland. England, Scotland, and Wales are the other divisions of the United Kingdom, which is often called the U.K. or Britain. Belfast is Northern Ireland's capital and largest city. Northern Ireland occupies the northeastern corner of the island of Ireland. It takes up about a sixth of the island. The independent Republic of Ireland occupies the rest. Northern Ireland is often called Ulster. Ulster was the name of a large province of Ireland until 1920, when Northern Ireland was separated from the rest of Ireland.

Religion has long divided Northern Ireland. About half of the people are Protestants, who have traditional ties to the rest of the United Kingdom. Nearly all the rest are Roman Catholics, as are most people in the Republic of Ireland. Most Protestants are unionists, who want Northern Ireland to remain in the United Kingdom. Most Catholics are nationalists, who want Northern Ireland to become part of the Irish Republic. The dispute sometimes led to riots, bombings, and other outbreaks of violence and terrorism, often called the troubles. A political settlement in 1998 promised an end to the troubles. But the agreement proved difficult to implement as the two sides struggled to overcome their mutual mistrust.

This article tells about the people, geography, economy, and history of Northern Ireland. For a discussion of the United Kingdom as a whole, see United Kingdom. For information on the Republic of Ireland, see Ireland.

Government

The United Kingdom is a constitutional monarchy. The monarch is the head of state, but a cabinet of officials called ministers actually governs. The prime minister, who chairs the cabinet, is the head of government.

Parliament. Laws for the United Kingdom are made by the British Parliament, which consists of the House of Commons and the House of Lords. Northern Ireland elects 18 of the 659 members of the House of Commons. The House of Lords consists mainly of honorary appointees. For more information on the British government, see United Kingdom (Government).

The Northern Ireland Office handles a variety of matters including human rights and law and order. The British prime minister appoints a secretary of state for Northern Ireland to head the office.

The 1998 political settlement created three new political bodies: the Northern Ireland Assembly, the North-South Ministerial Council, and the British-Irish Council. These groups began meeting in 1999.

The Northern Ireland Assembly assumes many of the responsibilities formerly handled by the Northern Ireland Office. It enacts local laws in such areas as agriculture, finance, and health and social services. Voters in Northern Ireland elect the Assembly's 108 members. Complex rules attempt to create a balance of power between unionists and nationalists.

The North-South Ministerial Council handles affairs of the entire island of Ireland. It includes representatives

Facts in brief

Capital: Belfast.
Official language: English.
Area: 5,467 mi² (14,160 km²). Greatest distances—east-west, 111 mi (179 km); north-south, 85 mi (137 km). Coastline—330 mi (531 km).
Elevation: Highest—Slieve Donard, 2,796 ft (852 m) above sea level. Lowest—The Marsh, near Downpatrick, 1.3 ft (0.4 m) below sea level.
Population: Estimated 2002 population—1,647,600; density, 301 per mi² (116 per km²); distribution, 70 percent urban, 30 percent rural. 1991 census—1,578,000.
Chief products: Agriculture—cattle, chickens, eggs, hogs, sheep. Manufacturing—aircraft, Irish linen and other textiles, machinery, pottery and china, ships.
from the governments of both Northern Ireland and the Republic of Ireland. The council’s decisions are subject to the approval of the Irish Parliament and the Northern Ireland Assembly.

**The British-Irish Council**, also called the Council of the Isles, addresses issues concerning all of Ireland and the United Kingdom. The council brings together representatives from the parliaments of Ireland and the United Kingdom; the assemblies of Northern Ireland, Scotland, and Wales; and the governments of the Channel Islands and the Isle of Man, two British dependencies.

**Local government.** Northern Ireland is divided into 26 districts, each governed by an elected council. Council members serve four-year terms. The councils handle such services as parks and environmental protection.

**People**

**Ancestry.** About half of the people are descended from English and Scottish settlers who arrived in Ireland since the 1600s. Most of the rest trace their ancestry to the earlier Celtic, Viking, and Norman settlers of the island of Ireland.

**Language.** English is the official language of Northern Ireland, and all the people there speak it. The Irish language, a form of Gaelic once used throughout Ireland, is taught to children in Roman Catholic schools and in some Protestant schools.

**Way of life**

About two-thirds of the people of Northern Ireland live in urban areas. Many live in or near the cities of Belfast and Londonderry, which is also called Derry. About a third of the people live in rural areas, and most of them earn their living by farming.

**Food and drink.** The people of Northern Ireland enjoy meals of meat, potatoes, vegetables, and bread. They also eat large amounts of poultry, eggs, dairy products, and fish. Tea is the most popular drink. A favorite alcoholic beverage is beer.

**Recreation.** Many people in Northern Ireland relax in the evening by watching television. Motion pictures are also popular. As in the rest of the United Kingdom, pubs (public houses) are an important part of the social lives of many people in Northern Ireland. People gather in pubs to drink beer and other beverages, eat sandwiches, talk with friends, and listen to music.

The most popular organized sport is football, the game Americans call soccer. Other popular sports include cricket, which is played with bats and a ball; Gaelic football, which resembles soccer; handball; hurling and camogie, which are somewhat similar to field hockey; and rugby, a game played with an oval ball. Many people also enjoy boating, fishing, golf, and swimming.

**Education.** All children in Northern Ireland from age 4 through 16 are required to attend school. Nearly all of them go to schools supported by public funds. Children attend a primary school from age 4 to 11. Some then attend a secondary school, which provides general and vocational education, or a grammar school, which prepares students for higher education. Others attend a comprehensive school, which provides both secondary and grammar school courses.

Catholics operate their own schools, so education in Northern Ireland is largely segregated along religious lines. However, some integrated schools have been established by Catholic and Protestant parents who are concerned about the continued segregation.

Northern Ireland has two universities. Queen’s University is in Belfast. The University of Ulster has branches in Belfast, Coleraine, Jordanstown, and Londonderry.

**Religion.** About half of the people are Protestants. Most of the rest are Roman Catholics. The Church of Ireland and the Presbyterian Church are the largest Protestant churches. The Church of Ireland belongs to the Anglican Communion, which also includes the Church of England and the Episcopal Church in the United States.

An organization of Protestant men called the Orange Order, also known as the Orangemen, holds parades every July 12. The parades celebrate the victory of King William III, a Protestant, over King James II, a Roman Catholic, in the Battle of the Boyne in 1690. The "Twelfth" is a public holiday in Northern Ireland. A similar association of Roman Catholics, the Ancient Order of Hibernians, holds parades on August 15 and sometimes on March 17. August 15 is the Roman Catholic Feast of the Assumption of the Virgin Mary. March 17 is St. Patrick’s Day. Saint Patrick is the patron saint of Ireland.

**The arts.** The most famous cultural event in Northern Ireland is the international arts festival hosted each November by the Queen’s University of Belfast. This festival features musical performances, dramatic productions, art exhibits, motion pictures, lectures, and other events.

The Ulster Orchestra and Opera Northern Ireland, both of which perform in Belfast, are well known. In addition, several musicians from Northern Ireland have established international reputations, including the flutist James Galway and the pianist Barry Douglas.

Northern Ireland is also known for talented writers. Poet Seamus Heaney won the 1995 Nobel Prize for literature. Other widely known writers include poet John Hewitt, novelist Brian Moore, and playwright Brian Friel.

**The land**

Northern Ireland lies on the northeast corner of the island of Ireland. On the south and west, it is bordered by the Republic of Ireland, which occupies the rest of the island. The North Channel separates Northern Ireland from Scotland to the northeast. The Irish Sea separates Northern Ireland from England to the southeast. For more information about the geography and climate of Northern Ireland, see the *land and Climate* sections in the *United Kingdom* article.
**Northern Ireland**

**Surface features.** Northern Ireland is a land of rolling plains and low mountains. The plains, which cover the central part of the region, include fertile fields and pasturelands. The mountains, which are near the coast, have many deep, scenic valleys. In some areas, he plains reach to the coast.

The highest peak in Northern Ireland is Slieve Donard pronounced sleev DAHN uhrd. It rises 2,796 feet (852 meters) in the Mourne Mountains near the southeast coast. Other mountain ranges include the Sperrin Mountains in the northwest and the Mountains of Antrim in the northeast.

**Lakes, rivers, and bays.** Northern Ireland has many smooth, clear lakes called loughs pronounced laksh. Lough Neagh (lahk NAY), near the center of the land, covers about 130 square miles (338 square kilometers). It is the largest lake in the United Kingdom and the largest body of water on the island of Ireland.

The longest river in Northern Ireland is the River Bann. The Bann is actually two rivers. The Upper Bann, which is 47 1/2 miles (76.4 kilometers) long, begins in the Mourne Mountains and flows northwest into the southern end of Lough Neagh. The Lower Bann begins at the northern end of the lake and flows north 38 miles (61 kilometers) into the Atlantic Ocean. Several large bays, which are also called loughs, cut into the coast. Lough Foyle and Belfast Lough provide excellent harbors for Londonderry and Belfast.

**Economy**

**Service industries** rank as leading employers. The major service industries include education, government services, health care, and wholesale trade.

**Manufacturing.** One of Northern Ireland's most famous manufactured products is Irish linen, which is known for its excellent quality. Most linen mills are near Belfast and Londonderry. Other mills produce woolen and cotton textiles and synthetic fibers.

Beautiful pottery and hand-cut crystal are also made in Northern Ireland. The village of Belleek in the district of Fermanagh is famous for its delicate china.

Shipyards in the Belfast area have built many warships, ocean liners, and tankers. Aircraft plants in the area make commercial and military planes. Other products manufactured in Northern Ireland include automobile parts, chemicals, computer chips, processed foods, and videocassette recorders.

**Agriculture and fishing.** Cattle, chickens, eggs, hogs, milk, potatoes, and sheep are among Northern Ireland's most important agricultural products. Much barley and hay are grown for animal feed. Other farm products include butter, cheese, mushrooms, and turnips. Orchards in the district of Armagh produce apples, pears, and plums.

The fishing fleet of Northern Ireland brings in large catches of cod, herring, mackerel, shrimp, and whiting, mainly from the Irish Sea. Salmon and trout are netted in the Rivers Foyle and Bann.

**Transportation and communication.** An excellent road system crisscrosses Northern Ireland. A government-operated railroad system links Belfast and Londonderry with each other, with Portadown and Bangor in
northern Ireland, and with Dublin in Ireland. Large amounts of freight pass through the seaports of Belfast, Coleraine, Larne, Londonderry, and Warrenpoint. Regular passenger ferry service connects Belfast and Larne with cities in western Scotland. Belfast International Airport is the only airport in Northern Ireland that handles international flights.

Northern Ireland has three daily newspapers, all published in Belfast. They are the *Belfast Telegraph*, the *Irish News*, and the *News Letter*. Two British Broadcasting Corporation television channels and two independent channels serve Northern Ireland.

**History**

This section deals mainly with the history of Northern Ireland from the Protestant settlement in the 1600's to recent developments. For information on the early history of the island of Ireland, see *Ireland* (History).

**Protestant settlement.** In 1541, King Henry VIII of England became king of Ireland. The Reformation, during which Henry changed England from a Roman Catholic to a Protestant nation, had little effect on Ireland. English rule there was ineffective, and most Irish people remained Catholics.

In 1607, local Irish chieftains who opposed the English fled from Ulster, a large province in northern Ireland. King James I of England then gave the chieftains' land to English and Scottish Protestants. This action was partly responsible for the Protestant majority found in Northern Ireland today.

In the 1600's, two attempts were made to reestablish Catholic power in Ireland. The first was an uprising that began in 1641 and was not put down by English forces until 1653.

The second attempt was made under James II, a Catholic who became king of England in 1685. Many English people were unhappy with James's policies and feared that a Catholic succession to the throne would be established. In 1688, the English invited William of Orange, a Protestant, to invade England with Dutch forces. James fled, and William of Orange was crowned as King William III in 1689. Meanwhile, James went to France and then to Ireland, where he organized an army to fight William. But James was defeated by William in the Battle of the Boyne in 1690. After the battle, Anglican Protestants owned most of the land in Ireland, controlled Ireland's Parliament, and restricted the rights of Catholics and Presbyterian Protestants alike.

**Union with Britain.** In 1801, the Act of Union took effect. This act abolished the Irish Parliament and created the United Kingdom of Great Britain and Ireland. During the 1800's, the standard of living in northern Ireland rose, as manufacturing flourished. But southern Ireland, where most of the Catholics lived, had a low living standard due to unequal distribution of land and a growing population.

In 1866, the British Liberal Party proposed a plan for Ireland called home rule. Under this plan, Ireland would have remained part of the United Kingdom, but it would have had its own parliament for domestic affairs. Ulster Protestants, who feared that such a parliament would be Catholic, opposed the plan. The plan was defeated in the British Parliament.

**The division of Ireland.** By the early 1900's, most Irish Catholics favored complete independence from Britain. But most of the Protestants in Ulster opposed independence because they did not want to be a minority in a Catholic country. In 1919, 73 Irish members of the British Parliament met in Dublin and declared all Ireland an independent state. Guerrilla warfare then broke out between the Irish rebels and British forces.

In 1920, the British Parliament passed the Government of Ireland Act. This act divided Ireland into two separate political units and gave each some powers of self-government. Ulster Protestants accepted the act, and the state of Northern Ireland was formed from six counties in Ulster. But southern Catholics rejected the act and demanded complete independence for a single, united Irish republic. In 1921, southern leaders and the United Kingdom signed a treaty that created the Irish Free State, from 23 southern counties and 3 counties of Ulster. In 1937, the Irish Free State adopted a new constitution and changed its name to Eire (in Gaelic) or Ireland (in English). In 1949, Ireland cut all ties with the United Kingdom and became an independent republic.

Under the 1920 act, Northern Ireland was given its own government, parliament, prime minister, and cabinet. The governor served as the official head of state, but the prime minister and cabinet held most of the power.

Northern Ireland's two-house Parliament handled such matters as administering the educational system and regulating commerce and agriculture. Certain other powers, such as levying income taxes and maintaining armed forces, were reserved for the British Parliament. Throughout Northern Ireland's period of self-rule, the Unionist Party—which favored continued union with the United Kingdom—controlled the government.

**Problems of division.** Many Roman Catholics in Northern Ireland refused to accept the 1920 division of Ireland, and the new government made little effort to win their loyalty. In some areas where Catholics formed a majority, election districts were set up to ensure that Unionist minorities won control of local councils.
The division of Ireland was also opposed by the Irishree State and, later, by the Republic of Ireland. Beginning in 1921, armed groups crossed into Northern Ireland and attacked British installations. They hoped to force the British to give up control of Northern Ireland.

The civil rights movement. Catholics in Northern Ireland had long claimed that Protestants violated their civil rights and discriminated against them in jobs, housing, and other areas. When the government tried to stop civil rights demonstration in Londonderry in 1968, bloody riots broke out. Serious riots occurred again in 1969 in Belfast and Londonderry. Troops were sent to Northern Ireland to restore order but failed to prevent further rioting. Meanwhile, the pro-Catholic Irish Republican Army (IRA) and other militant groups carried out bombings and other terrorist attacks.

The continuing conflict led the British government to suspend Northern Ireland's government in 1972 and to rule the region directly from London. But the troubles continued. In 1973 and 1982, the United Kingdom set up assemblies in Northern Ireland that were designed to restore control over local affairs to the region. However, lack of cooperation between the Protestants and Catholics led the British government to dissolve both assemblies.

In 1985, the United Kingdom and the Republic of Ireland signed the Anglo-Irish Agreement, which gave the government of the Irish Republic an advisory role in Northern Ireland's affairs. Both Unionists and the IRA strongly opposed the agreement, and protests against the British government took place.

In the late 1980's and early 1990's, terrorist bombings by the IRA and related groups intensified. The attacks led to violent responses by Protestant terrorist groups. In 1994, the IRA and the Protestant groups declared cease-fire, but bombings resumed in 1996.

Recent developments. Another cease-fire was announced in mid-1997. In September of that year, formal negotiations began that aimed to end the violence over Northern Ireland. The talks were the first to include all parties involved in the conflict. In April 1998, the talks ended with an agreement that was then put to referendums in both Ireland and Northern Ireland. Voters approved the agreement, which included a commitment to sing peaceful means to resolve political differences. The agreement called for the establishment of a Northern Ireland legislative assembly with control over many local matters. It also called for the establishment of a north-South Ministerial Council, which would include government representatives from Northern Ireland and the Republic, and for a British-Irish Council, which would include representatives from the Irish parliament and the various legislative assemblies of the United Kingdom. In 1999, implementation of the agreement was delayed by disagreements over IRA disarmament.

The new governing bodies began meeting in December 1999. Early in 2000, the agreement was suspended when the Protestants threatened to withdraw from the government to protest a lack of disarmament by the IRA. After months of negotiations, the IRA proposed a new disarmament plan, and the power-sharing government resumed. The government was threatened again in 2001 by further disagreements over IRA disarmament. These disputes were resolved later in 2001 when international monitors confirmed that the IRA had begun to disarm.

Northern lights. See Aurora.

Northern Mariana Islands, Commonwealth of the, is a chain of 16 islands in the Pacific Ocean. The islands are a commonwealth of the United States. They lie about 1,000 miles (1,600 kilometers) south of Japan and about 1,500 miles (2,400 kilometers) east of the Philippines.

The Northern Marianas extend about 337 miles (543 kilometers) from north to south and cover about 184 square miles (477 square kilometers) of land. They are part of a larger region in the Pacific Ocean called Micronesia. Together with Guam, the Northern Marianas make up the Marianas Islands.

About 87,000 people live in the Northern Marianas. About 90 percent of the population lives on Saipan, the capital and largest island. Most of the rest of the people.
Northern Mariana Islands

There are about 14 schools in the Northern Marianas, including a two-year college. The law requires children from 6 through 16 years of age to attend school. English is the main language of instruction.

Many houses on the islands are made of wood or cement block with sheet metal roofs. Modern apartment buildings and condominiums have been built on Saipan.

**Land and climate.** The Northern Marianas are formed by the peaks of a huge undersea mountain range. The range rises more than 6 miles (9.5 kilometers) off the bottom of the Mariana Trench, the deepest known spot in the world’s oceans. The northern islands are covered with volcanic rock. Seven of them—Alamagan, Anatahan, Agrihan, Farallon de Pajaros, Guguan, Sarigan, and Pagan—still have active volcanoes. Limestone terraces cover volcanic rock on the southern islands. The Maug Islands, a cluster of three islands, are sometimes counted as one island. The Northern Marianas have an average year-round temperature of about 84 °F (29 °C) and an average annual rainfall of about 84 inches (213 centimeters).

**Economy.** The government is the major employer in the Northern Marianas. Tourism ranks as the most important economic activity. The garment industry is the only significant manufacturing activity. Imports in the Northern Marianas far outnumber exports. More than half of the work force in the Northern Marianas are foreigners. The majority of the garment workers are Chinese or Thai. Many islanders hold government jobs.

**History.** The ancestors of the present-day Chamorros had begun living on the Northern Marianas by about 1500 B.C. In A.D. 1521, Ferdinand Magellan, a Portuguese explorer in the service of Spain, discovered Rota and Guam. Spain claimed the islands in 1565. But Spain did not begin ruling them until 1668, after Spanish Jesuits established a missionary settlement on Guam.

At the end of the Spanish-American War in 1898, Spain turned Guam over to the United States. The next year, Spain sold the Northern Marianas to Germany. Germany ruled the Northern Marianas until the Japanese seized them at the beginning of World War I in 1914. After the war ended in 1918, a mandate from the League of Nations gave Japan control of the islands.

The United States gained control of the Northern Marianas in 1944, during World War II. In 1947, the United States began administering the islands as part of the United Nations Trust Territory of the Pacific Islands. In 1975, the United States agreed to make the Northern Marianas a self-governing U.S. commonwealth. The agreement took effect Nov. 3, 1986. Michael R. Ogden

**Northern Territory** is a tropical area in north-central Australia. It has large regions of only partly explored land. The Northern Territory covers 519,800 square miles (1,346,200 square kilometers). Its population of 175,253 includes many Aborigines whose ancestors lived in Australia before white people arrived (see Australia [The Aborigines]). Tribal conditions still exist among some of the Aborigines. Darwin is the capital and largest city in the Northern Territory. For a detailed map of the area, see Australia [political map].

The territory's flat coastline of 1,040 miles (1,674 kilo-
Darwin is the capital and largest city of the Northern Territory of Australia. It is also the chief port of the territory. The city lies along Australia's northern coast on the Beagle Gulf, an arm of the Indian Ocean. It is named in honor of the British naturalist Charles Darwin.

The Northern Territory covers a huge area in north-central Australia. The interior of the territory is dry and flat except for some low mountains and scattered rock formations.
elections two members to the federal Senate. The federal government provides medical services for the Northern Territory. A "Flying Doctor" operation uses radio and aircraft service to help the sick and injured at isolated mines and cattle stations.

The explorer John McDouall Stuart first entered the Northern Territory in 1860. His explorations opened up much of the area. An overland telegraph line, completed in the 1870s, followed Stuart's trail from Adelaide to Darwin. The Northern Territory was part of New South Wales until 1863 when it was annexed to the province of South Australia. The Australian federal government took over the administration of the territory in 1911. In 1978, the federal government granted the Northern Territory self-government. K. H. White

Northfield (pop. 17,147) is a city in southeastern Minnesota. It lies about 40 miles (64 kilometers) south of St. Paul. For location, see Minnesota (political map). The notorious Jesse James gang tried to rob a bank in Northfield in 1876, but the bank clerk refused to open the vault. James escaped, but several gang members were killed or captured. The bank is now a historical museum. The city is the home of Carleton and St. Olaf colleges. Northfield is a business processing and the production of electronic circuits. The city is named for John W. North, who founded it in 1855. Northfield has a mayor-council form of government. Clifford E. Clark, Jr.

Northrop, John Howard (1891-1987), an American biochemist, shared the 1946 Nobel Prize in chemistry with James B. Sumner and W. M. Stanley. Northrop prepared the crystalline form of several pure enzymes and one of the viruses that destroy bacteria (see Enzyme). Northrop's writings on enzymes include Crystalline Enzymes (1939). He was born in Yonkers, New York. He received his doctor's degree from Columbia University in 1915 and was a member of the Rockefeller Institute (now Rockefeller University) in New York City from 1924 until his death. Eric Howard Christianson

Northwest Ordinance was an important law passed by the United States Congress on July 13, 1787. The ordinance provided for the government of the region north of the Ohio River and west of Pennsylvania, then called the Northwest Territory. It became a model for territories that later entered the Union as states. The ordinance was largely the work of General Nathan Dane and political leaders Rufus King and Manasseh Cutler.

Under the terms of the ordinance, the territories could achieve equality with the older states by passing through three steps leading to full self-government: (1) Congress, which governed the territory, appointed a governor, a secretary, and three judges. (2) When the territory, or any division of it, attained an adult male population of 5,000, it could choose a legislature and send to Congress a delegate who could speak there but not vote. (3) When the total population reached 60,000, the territory could apply for admission into the Union on terms of full equality with the older states. The ordinance removed the danger of colonial rebellion because it assured the territories of participation in the national government.

The Northwest Ordinance provided more than a plan of government. It laid the groundwork for social and political democracy in the West. It forbade slavery. All people were guaranteed trial by jury and freedom of religious worship. The ordinance guaranteed fair treatment for the Indians and declared that "means of education shall forever be encouraged."

The terms of the Northwest Ordinance were so attractive that pioneers poured into the new territory. In 1788, one of the first groups of settlers founded the town of Marietta, Ohio. Thousands of families followed the first settlers in the westward movement. The territory eventually became five states—Ohio, Indiana, Illinois, Michigan, and Wisconsin. The territory included what is now the part of Minnesota east of the Mississippi River. William E. Foley

Additional resources

Northwest Passage is a water route, long sought by explorers, across or around North America. The explorers who followed Christopher Columbus soon found that North America was not a part of Asia, as they had believed at first. At that time, English, French, and Dutch adventurers were more interested in finding an easy route to Asia than they were in exploring and settling North America. So they began to look for a "Northwest Passage," or waterway, that would take them around or through the North American continent.

The search for the Northwest Passage is a tale of adventure and heroism. In 1524, Giovanni da Verrazzano, sailing under the French flag, tried to find the passage. He probably explored as far north as Maine.

Jacques Cartier, while exploring for France in 1535, found the St. Lawrence River. He was seeking a route to China. Henry Hudson was sent out many years later by the Dutch East India Company to find a shorter route to the South Seas. He thought he had found that route in 1609 when he sailed into New York Bay and some distance up the Hudson River. In 1610, Hudson explored the Hudson Strait and Hudson Bay while searching for the Northwest Passage.

No country tried harder than England to find the passage. Sir Martin Frobisher began a series of English expeditions in 1576. Other English navigators continued these explorations for 300 years. Frobisher made many important findings, including Frobisher Bay, an indentation in Baffin Island. John Davis followed Frobisher and sailed into the strait that now bears Davis' name. In 1616, William Baffin and Robert Bylot sailed up Davis Strait and around the great channel that has ever since been known as Baffin Bay. Russia, the Netherlands, and Denmark took an interest in the search.

By the late 1700's, the territory that had been explored included Hudson Strait, Hudson Bay, Davis Strait, Baffin Bay, and the icy seas from Greenland to Svalbard and from Svalbard to Novaya Zemlya. See Exploration.

Commander John Ross, a Scottish explorer, began the final series of expeditions in 1818. The most noted of the explorers to follow him was Sir John Franklin, a British explorer. Franklin found a passage to Asia during a voy-
Northwest Passage

his map shows routes traveled by explorers in search of northern sea passage between Europe and Asia.

- Henry Hudson 1610-1611
- Sir John Franklin 1845-1847
- Sir Robert McClure 1850-1854
- Roald Amundsen 1903-1906
- S.S. Manhattan 1969

In 1845, Sir John Franklin's ships reached King William Island, near waters that led directly to the Asian shore; however, Franklin and his crew died after their ships became jammed in the ice, and their discovery was not known until later expeditions found relics of their trip. In 1850, Sir Robert McClure, a British explorer, sailed through a passage to the northern shore of what is now Banks Island. Thick ice halted his voyage. But McClure and his crew continued by sled and ship and, in 1854, completed the first journey through the Northwest Passage.

In 1906, Roald Amundsen's ship, the Gjoa, completed the first trip through the Northwest Passage. Amundsen sailed east to west. The first west-to-east voyage as completed in 1942 by the Royal Canadian Mounted Police schooner St. Roch.

McClure Strait was conquered in 1954 by United States Navy and Coast Guard icebreakers. Three U.S. Coast Guard cutters, the Spar, the Bramble, and the Storis, aided by the Canadian Navy icebreaker the Labrador, made the west-to-east trip in 1957. They traveled through Bellot Strait. This channel permits cargo ships to unload supplies for the North Warning System radar line in northern Canada. The Spar was the first ship to sail completely around North America on a continuous voyage. It started in Bristol, Rhode Island, went south to the Panama Canal, then up the Pacific Coast, through the Northwest Passage, and back to Bristol.

In 1960, the U.S. atomic submarine Seadrake made the first underwater crossing of the Northwest Passage.

The Investigator, a ship captained by the British explorer Sir Robert McClure, sailed to the north shore of Banks Island in 1850. There, thick ice prevented further sailing. But McClure and his crew continued by sled and ship, completing the first expedition through the Northwest Passage in 1854.
It traveled 850 miles (1,368 kilometers) from Lancaster Sound, through the Canadian Arctic islands, and into McClure Strait. In 1969, the U.S. icebreaker-tanker *Manhattan* became the first commercial ship to complete the passage. The *Manhattan* sailed to Alaska by way of the Prince of Wales Strait.

**Additional resources**

**Northwest Territories** is a vast region in northern Canada. It stretches from the northern boundaries of the provinces of British Columbia, Alberta, and Saskatchewan north to islands in the Arctic Ocean. It lies between the Yukon Territory in the west and the territory of Nunavut in the east. Until April 1, 1999, Nunavut had been part of the Northwest Territories.

The Northwest Territories is sparsely populated. Its people include Inuit, Indians, people of European descent, and *metis* (people of mixed European and Indian ancestry). Yellowknife is the capital.

**The land**

The Northwest Territories has two geographic areas: the Mackenzie Valley and the High Arctic. The tree line, the northern limit of forest growth, separates the Mackenzie Valley and the High Arctic.

The *Mackenzie Valley* area lies east of the Yukon Territory and south of the tree line. A majority of the people of the Northwest Territories live in the Mackenzie Valley area. This geographic region includes the rugged Mackenzie Mountains, which rise along the length of the Yukon boundary from British Columbia in the south to the Beaufort Sea in the north. High peaks include Mount Sir James MacBrien (9,062 feet, or 2,762 meters) and Dome Peak (9,000 feet, or 2,743 meters).

East of the Mackenzie Mountains is the Mackenzie
The spectacular scenery of the Northwest Territories includes Alexandra Falls on the Hay River south of Great Slave Lake. The southern part of the vast, rugged Territories includes mountains, lakes, and rivers. The northern part is a cold, harsh area of islands and icy waters.

River Valley itself, a northward continuation of the Great entral Plain of North America. The Mackenzie River is the longest river in Canada and one of the largest watersheds in North America. The river flows northwest for 1,000 miles (1,770 kilometers) from Great Slave Lake to the Beaufort Sea. Communities on the banks of the Mackenzie River include Fort Simpson, Norman Wells, Fort Norman, Fort Good Hope, and Inuvik. Birch, larch, pine, poplar, and spruce trees are common in the area, which serves as a source of forest products.

East of the Mackenzie River are the Franklin Mountains, which rise to elevations of about 5,000 feet (1,500 meters). Two of the largest lakes in Canada, Great Bear Lake and Great Slave Lake, lie east of the Franklin Mountains. The capital city of Yellowknife stands on the shores of Great Slave Lake.

To the southwest of the Mackenzie River is the World Heritage Site of Nahanni National Park. World Heritage sites have been chosen by the United Nations Educational, Scientific and Cultural Organization (UNESCO) as areas of unique natural or cultural importance. The park features towering mountains and thundering waterfalls. Wood Buffalo National Park, another World Heritage Site, extends into the province of Alberta from the southern part of the Territories. One of the largest herds of buffalo in Canada roams the park, and whooping cranes nest there in the spring.

The High Arctic region of the Northwest Territories lies north of the tree line and includes several islands in the Arctic Ocean. Much of the area is covered by a rolling, rocky terrain called barrenlands, which is dotted with lakes and rivers. The vegetation there consists of shrubs and small trees. The chief communities of the High Arctic include Holman, Sachs Harbour, Tuktoyaktuk, and Paulatuk. The Inuvialuit people, also called the Mackenzie Inuit, make up most of the population of the High Arctic in the Northwest Territories.

Climate

The Northwest Territories has long, cold winters and short, cool summers. Summers in the Mackenzie Valley
region are warmer than those in the High Arctic area. Inuvik, in the Mackenzie Valley area, has average temperatures of 56 °F (13 °C) in July and −18 °F (−28 °C) in January. Temperatures in Fort Smith, in the far south, average 61 °F (16 °C) in July and −13 °F (−25 °C) in January. The High Arctic area has an average July temperature of about 52 °F (11 °C), and January temperatures range around −25 °F (−32 °C). The highest temperature recorded in the Northwest Territories was 103 °F (39 °C) at Fort Smith on July 18, 1941. The lowest, −71 °F (−57 °C), also occurred there, on Dec. 26, 1917.

There are 20 hours of daylight each day in June in the southern Northwest Territories. The northern Northwest Territories is in the "land of the midnight sun." There, daylight lasts 23 hours a day for most of June and July.

Most of the Territories receives little moisture. The average annual precipitation is 11 inches (27 centimeters). Most of it falls as snow. About 60 inches (150 centimeters) of snow falls every year on the mainland and less than 40 inches (100 centimeters) on many islands.

People

Indians, Inuit, and métis make up nearly half the population. Most of the rest of the people are of European descent. The various Indian groups in the area refer to themselves together as Dene, which means people. Individual Indian groups in the Territories include the Bear Lake Indians, also called the Sahtu Gtine; the Chipewyan; the Dogrib; the Gwich'in, also called the Kutchin; the Hare; and the Slavey. The Inuit of the Northwest Territories are often referred to as the Inuvialuit.

The Northwest Territories has about 33 scattered communities. Yellowknife is the only city in the region and the largest populated center. Fort Smith, Hay River, Inuvik, and Norman Wells are incorporated towns.

Economy

Mining contributes more to the economy of the Northwest Territories than any other economic activity. Diamonds rank as the region's leading mined product. In 1998, the first diamond mine in Canada was officially opened near Lac de Gras, about 186 miles (300 kilometers) north of Yellowknife.

Oil, which ranks second, is produced at a field near Norman Wells. Natural gas deposits have been found in the Mackenzie Delta and the Liard Valley. Gold ranks third among the mined products of the Northwest Territories. Gold mining is centered in the Yellowknife area.

Government service. A major employer in the Northwest Territories is government. About one-seventh of the population is employed in the federal, territorial, or municipal governments.

Tourism is becoming an increasingly important part of the economy of the Northwest Territories. People visit the Territories to enjoy its rugged natural beauty and to engage in such activities as hunting and skiing. Many tourists also come to the Northwest Territories during the winter months to observe the natural display of light in the sky called the aurora borealis or northern lights. See Aurora.

Fishing industry. Almost all commercial fishing in the Territories is carried out on Great Slave Lake. The lake supplies whitefish and lake trout.

Forest industry. Forest products from the Northwest Territories come mainly from birch, pine, poplar, and spruce trees. Sawmills are south of Great Slave Lake at Fort Resolution, Hay River, and Fort Liard.

Transportation. Great distances and a small number of passengers make transportation expensive in the Northwest Territories. The cheapest and oldest form of transportation in the area is by water. But the main water route, the Mackenzie River, is frozen for eight to nine months each year. A tug and barge service operates from the Hay River terminal of the Mackenzie Northern Railway on Great Slave Lake. The route continues along the Mackenzie River to the Beaufort Sea. Barges on the Slave and Athabasca rivers operate in the far south.

Scheduled air services operate in both the Mackenzie Valley and the High Arctic. Seaplanes take supplies to mining and prospecting communities. Jet aircraft serve Fort Smith, Hay River, Inuvik, Norman Wells, and Yellowknife. The Mackenzie Northern Railway provides

Yellowknife is the capital and largest city of the Northwest Territories of Canada. It lies on Yellowknife Bay, a projection at the northern end of Great Slave Lake.
An oil rig drills for petroleum near Norman Wells, on the Mackenzie River. Petroleum production is an important economic activity in the Northwest Territories.

A freight service between Alberta and Hay River. The railroad runs parallel to the Mackenzie Highway. Most of the region's highways are paved. Temporary ice roads serve as winter supply routes for some communities.

Communication. Newspapers are published in most of the main Northwest Territories communities. The Canadian Broadcasting Corporation has radio stations in Yellowknife and Inuvik. A telecommunications satellite system provides radio, telephone, and television to all communities in the Territories.

Education

Schools in Yellowknife are operated by two district education authorities—public and Roman Catholic. In the rest of the Territories, regional education boards coordinate the activities of the schools within the boundaries of their authority. For the number of students and teachers in the Territories, see Education (table).

Aurora College is the only college in the Northwest Territories. It has campuses in Fort Smith, Inuvik, and Yellowknife. The territorial government provides grants and loans for Northwest Territories students who wish to attend Aurora College or universities and colleges outside of the Territories.

Government

The people elect one member to the Canadian House of Commons. The Northwest Territories has one representative in the Canadian Senate.

The federal government appoints a commissioner to serve as honorary head of government for the Territories. A premier actually leads the government. The premier heads an Executive Council (cabinet). The Legislative Assembly of the Territories elects the premier and the council from among its own members.

The 14 members of the Legislative Assembly are elected to four-year terms. The Assembly governs by consensus—that is, by general agreement. The Northwest Territories has no political parties. The territorial government has branch offices in several communities throughout the Territories.

The court system of the Territories includes the Court of Appeal, the Supreme Court, and the Territorial Court. The Court of Appeal handles appeals of criminal and civil cases from the Supreme and Territorial courts. It consists of three judges, all of whom are appointed by the federal government. The Supreme Court tries various civil and criminal cases and hears appeals of some cases from the Territorial Court. The Supreme Court consists of a senior justice and two other justices. The federal government appoints all three of the justices. The Territorial Court handles cases involving small claims, young offenders, and criminal law. It also has some authority over family law cases. Its three judges are appointed by the commissioner of the Territories.

The Northwest Territories has several settlement areas that have been set up as a result of land claim agreements with aboriginal peoples—that is, the Inuit and Indians—and métis. In general, these agreements recognize aboriginal control over the lands in the settlement areas. The agreements also call for the establishment of resource boards in the areas. These boards include government representatives and representatives of the aboriginal peoples. They enact measures concerning a number of issues, including the management of land, water, and wildlife in the settlement areas. Settlement areas in the Territories include the Inuvialuit, Gwich'in, and Sahtu regions.

History

Inuit and Indians lived in the Northwest Territories for thousands of years before Europeans arrived. The first white person to cross the Territories by land was Samuel Hearne of the Hudson's Bay Company, a British fur-trading firm. He set out in 1770 from Churchill in present-day Manitoba. Traveling overland, he reached the mouth of the Coppermine River in 1771 and explored the Great Slave Lake region on the return journey. In 1789, Alexander Mackenzie reached the river that now bears his name.

Creation of the Northwest Territories. In 1870, the Canadian government organized two newly acquired regions—Rupert's Land and the North West Territory—into the North West Territories, which later became known as the Northwest Territories. The Canadian government then became responsible for the administration of the region. The eastern part of the North West Territories—that is, Rupert's Land—had belonged to the Hudson's Bay Company since 1670. The North West Territory lay north, west, and south of Rupert's Land.

The Territories lost part of the Manitoba area in 1870, when Manitoba became a province. The Yukon Territory was cut off in 1898, and the provinces of Alberta and Saskatchewan in 1905. In 1912, Manitoba, Ontario, and Quebec acquired certain areas.

The early and middle 1900's. The discovery of radi-
Symbols of the Northwest Territories

The territorial flag, which bears most of the coat of arms, was adopted in 1969. On the coat of arms, the wavy blue line represents the Northwest Passage. The gold bars symbolize the Territories' mineral wealth. The white fox represents the fur industry. Two narwhals (arctic whales) guard a compass rose, which symbolizes the magnetic north pole. The coat of arms was adopted in 1957.

1960's to serve mining operations that lasted for a time in Pine Point. In 1967, Yellowknife became capital of the Territories. The federal government began transferring its administrative responsibilities in the Northwest Territories to the territorial government in Yellowknife.

Recent developments. For many years, Inuit of the Northwest Territories called for their own political unit in the east. In 1982, the people voted to divide the Territories into two political units—eastern and western territories. In 1992, the people of the Northwest Territories voted and approved a boundary to divide the territories. The Inuit territory, in the east, was to be called Nunavut. In 1993, the Canadian Parliament approved the division of the Northwest Territories and passed legislation to create Nunavut. The new territory came into being on April 1, 1999. With the creation of Nunavut, the size of the Northwest Territories shrank from 1,322,910 square miles (3,426,320 square kilometers) to 501,570 square miles (1,299,070 square kilometers).

Additional resources

Northwest Territory was a vast tract of land lying north of the Ohio River, west of Pennsylvania, and east of the Mississippi River. It extended to the northern limits of the United States. The states of Ohio, Indiana, Illinois, Michigan, Wisconsin, and part of Minnesota east of the Mississippi were carved out of the Northwest Territory.

Early history. The French, who first occupied the region, had established posts by the early 1700's. Competition between French traders operating from these posts and British trappers from Pennsylvania helped start the French and Indian War (1754-1763). The war ended with the cession of the area to a victorious United Kingdom. See French and Indian wars.

During the Revolutionary War (1775-1783), violent fighting took place in the Northwest between the settlers and the British and their Indian allies. The campaign of George Rogers Clark against British-controlled settlements helped win the territory for the United States. The region was ceded after the war. Before the government could open the region to settlement, it had to deal with the claims of Massachusetts, Connecticut, Virginia, and New York. These states insisted that their colonial charters extended their boundaries into this area. The states ceded their claims to Congress between 1781 and 1785, because Maryland refused to approve the Articles of Confederation until it received assurance that the other states would yield their claims.

The land then became a territory of the United States.
Northwest Territory's first settlement and its first capital were established at Marietta, Ohio, in 1788. The engraving of the Marietta courthouse and jail shown here dates from 1842.

Congress, eager for revenue from the sale of lands titles, adopted the Ordinance of 1785. This law provided for orderly triangular surveys into mile-square units called sections. These were sold at auction at a minimum price of $1 an acre. Congress also struggled with the problem of a government for the territory. Thomas Jefferson in 1784 had drafted a plan that would have divided the territory into several units. These could become states when the population of any one unit exceeded the population of the smallest state in the Union. The Western States rejected this proposal, because they feared that the many Western States would dominate Congress. Instead, Congress adopted the Northwest Ordinance, or Ordinance of 1787. This provided for the division of the region into from three to five states, and the establishment of a governmental system that would allow them eventual membership in the Union. See Northwest Ordinance.

Settlement began at once. The first arrivals were sent by a New England speculate group called the Co Company (see Ohio Company). They founded the town of Marietta at the mouth of the Muskingum River in Ohio. Other interests soon established rival settlements at such villages as Gallipolis and Cincinnati. To the north, colonists clustered about Cleveland in the Western Reserve area retained by Connecticut when it ceded its lands to Congress (see Western Reserve). Aaron St. Clair became the first governor of the Northwest Territory in 1787. He inaugurated the territorial government on July 15, 1788.

The population grew slowly at first because of continuing Indian attacks. President George Washington sent the expeditions to fight the Indians, but the first two met with disaster. The territory became more peaceful when General Anthony Wayne defeated the Indians in the Battle of Fallen Timbers in 1794. In 1795, Wayne signed the Treaty of Greenville on the defeated Indians. The Treaty of Greenville, the Indians ceded most of the lands of southern Ohio and part of eastern Indiana to the United States. Other land cessions followed during the early 1800's. See Indian wars (Along the frontier).

As more settlers moved into the region, the Northwest Territory was divided. In 1800, the western part of the region became the Territory of Indiana, with William Henry Harrison as governor. The Michigan Territory was created in 1805, and the Illinois Territory in 1809. Ohio became a state in 1803, Indiana in 1816, Illinois in 1818, Michigan in 1837, and Wisconsin in 1848.

Additional resources

Northwestern University is a private coeducational institution with campuses in Evanston and Chicago, Illinois. The main campus, in Evanston, has a college of arts and sciences; schools of education and social policy, engineering and applied science, journalism, music, and speech; a graduate school; and a graduate school of management. The Technological Institute and the National High School Institute are also at the Evanston campus. Northwestern grants bachelor's, master's, and doctor's degrees.

The Chicago campus serves as a center for professional studies. The McGaw Medical Center, one of the world's largest private medical centers, is based there. It includes the university's dental and medical schools, and has five member hospitals in the Chicago area—Children's Memorial Hospital, Evanston Hospital, Northwestern Memorial Hospital, the Rehabilitation Institute of Chicago, and the Department of Veterans Affairs Lakeside Medical Center. The university's law school and its University College are also on the Chicago campus. The University College offers summer and continuing education courses and some degree programs.

Northwestern was the first university in the United States to establish a school of speech and to sponsor a children's theater. Its law school was the first to organize a scientific crime detection laboratory. The university also established the first program in African studies. Its Center for Materials Science, Center for Urban Affairs, and Transportation Center are nationally known.

Northwestern University was founded in 1851. The Chicago campus opened in 1926.

Critically reviewed by Northwestern University

Norton, Andre (1912— ), is an American author of science fiction. She has written more than 100 books, most of them for young people. Norton often draws on history and folklore for her action-packed plots, which include such elements as magic, time travel, and animals with powers of telepathy.

Norton's first books were spy stories and historical novels. Her first science-fiction book was Star Man's Son, 2250 A.D. (1952). Other books include The Beast Master (1939), Operation Time Search (1967), Wraiths of Time (1976), and Dare to Go A-Hunting (1990).

Norton was born in Cleveland. From 1932 to 1951, she worked as a children's librarian there. Norton's given name was Mary Alice. She changed her name to Andre because of concerns that her first novel, The Prince Commands (1934), would not be accepted if publishers knew her author was a woman. Norton has also written science fiction under the pen name Andrew North.

Kathryn Pierson Jennings
Norway is known for the scenic beauty of its rugged mountains and its deeply indented coast. Many inlets of the sea called fiords extend far into the country. The village of Stryn on the Nord Fiord, shown here, lies about 60 miles (100 kilometers) from the coast.

Norway

Norway is a long, narrow country on the northwestern edge of the European continent. The northern third of Norway lies above the Arctic Circle and is called the Land of the Midnight Sun. Because this region is so far north, it has long periods every summer when the sun shines 24 hours a day. Oslo, Norway’s capital and largest city, is in the southern part of the country.

Most of the Norwegian people live near or along the sea. Winds warmed by the sea give the coast much warmer winters than other regions so far north, and snow melts quickly there. Even north of the Arctic Circle, nearly all of Norway’s harbors are free of ice the year around. Inland areas are colder, and snow covers the ground much of the year. For thousands of years, the people have used skis for travel over the snow. Today, skiing is Norway’s national sport. Most Norwegians learn to ski before they even start school.

Norway, along with Denmark and Sweden, is one of the Scandinavian countries. Vikings lived in all three countries about a thousand years ago. Vikings from Norway sailed west and established colonies in Iceland and Greenland. About A.D. 1000, Leif Ericson sailed from Greenland and headed what was probably the first European expedition to the mainland of America.

Since the time of the Vikings, the Norwegians have been a seafaring people. Norway’s coast is famous for its many long, narrow inlets of the sea called fiords, which provide fine harbors. Rich fisheries lie off the west coast and dried fish were an important export as early as the 1200’s. Norway began developing its great shipping fleet during the 1600’s. Today, Norway’s fishing and shipping industries rank among the world’s largest.

Norway is mostly a high, mountainous plateau covered by bare rock, and it has a relatively small amount of farmland. But the rivers that rush down from the mountains provide many hydropower sites.

Facts in brief

Capital: Oslo.
Official language: Norwegian (Bokmål and Nynorsk).
Official name: Kongeriket Norge (Kingdom of Norway).
Area: 149,405 mi² (386,958 km²), including Svalbard and Jan Mayen. Greatest distances—northeast-southwest, 1,089 mi (1,752 km); northwest-southeast, 267 mi (428 km). Coastline—1,647 mi (2,650 km).
Elevation: Highest—Galdhoppigen, 8,100 ft (2,469 m) above sea level. Lowest—sea level along the coast.
Population: Estimated 2002 population—4,505,000; density, 30 per mi² (12 per km²); distribution, 74 percent urban, 26 percent rural. 1990 census—4,247,546.
National anthem: ”Ja, vi elsker dette landet” (Yes, We Love This Land).
Money: Basic unit—krone. One hundred ore is equal one krone.

Terje I. Leiren, the contributor of this article, is Professor of Scandinavian Studies at the University of Washington.
The midnight sun is a famous symbol of Norway. It shines 24 hours a day for 10 weeks each year at North Cape, shown here, the rocky point of land on the shore of the Arctic Ocean.

Laws provide cheap electric power. Norway generates more hydroelectric power per person than any other country. Norwegian manufacturing is based on this cheap power.

Government

Norway is a constitutional monarchy with a king or a queen, a Cabinet led by a prime minister, and a parliament. The government is based on the Norwegian Constitution of 1814, which divides the government into three branches—executive, legislative, and judicial. The prime minister is the actual head of the government. The monarch has little power.

The monarch usually appoints the leader of the strongest political party or coalition (group of parties) in the parliament to be prime minister. Other high government officials, including judges and county governors, are appointed by the monarch on the advice of the Cabinet. Like the other Scandinavian countries, Norway has a government official called an ombudsman. This official investigates complaints by citizens against government actions or decisions. See Ombudsman.

National government. Executive power in the Norwegian government is exercised by the Cabinet, also known as the Council of State. It consists of the prime minister and about 18 other officials, each of whom heads a department or ministry. The monarch officially appoints the Cabinet members, but they are actually selected by the party or coalition in power in the parliament. To keep the powers of the executive and legislative branches separate, Cabinet members cannot also

Oslo, Norway’s capital and largest city, is home to almost 1 of 8 Norwegians. Oslo is also the chief commercial, industrial, and shipping center of Norway.

The Norwegian flag was first approved for use by merchant ships in 1821. It became the national flag in 1898.

Norway’s coat of arms dates from the 1280s, when the ax and crown of Saint Olav were added to the lion.

Norway is a country in northern Europe. It borders Sweden, Finland, and Russia.

members of the parliament.
The Cabinet is responsible for forming government policies. A Cabinet remains in office as long as it has the support of a majority of the parliament. The Cabinet must resign if it loses a vote of confidence in the parliament. If a vote of no confidence or some other government crisis occurs, an alternate Cabinet—usually from minority party—is appointed to govern during the rest of the parliament's term.
The parliament, Norway's lawmaking body, is called the Storting. It consists of 165 members elected to four-term years. Each of Norway's 19 counties elects 4 to 15 members, depending on its population. An additional eight members are chosen from national electoral lists. The Storting consists of one house. But after each election, its members form two sections to discuss and vote on proposed laws. They elect 39 of their number to the aging. The remaining 126 members make up the Odelsting.

To become law, most bills must first be approved by the Odelsting and then by the Lagting. If the two sections do not agree on a bill, it can be approved by two-thirds of the parliament as a whole. Certain matters, including bills that deal with taxation and spending, are voted on only by the entire parliament.

Courts. Norway's highest court is the Supreme Court of Justice. Five Superior Courts try the most serious cases and hear appeals of decisions made by the county and town courts. Each county and town also has a Constitution Council, which tries to settle disputes before they go to court. This body consists of three people elected to four-year terms.

Local government. Norway has 19 counties, one of which is the city of Oslo. Each of the counties, except Oslo, has a governor. Norway's cities, towns, and village districts elect councils of varying size to four-year terms. These councils select a chairman, or mayor, who serves two years.

Politics. Norway has several major political parties. The largest is the socialist Labor Party. Members of the Labor Party favor social welfare programs, and they also support government action to foster economic growth and full employment. The Conservative Party's members support lower taxes and less government control of the economy. The Christian People's Party is a center-right party whose members promote democracy based on a Christian outlook.

Norway's other major political parties include the center party, the Liberal Party, the Progress Party, and socialist Left Party. All Norwegians who are at least 18 years old can vote.

Armed forces. Norway's army, navy, and air force have a total of about 34,000 troops. Norwegian men between the ages of 19 and 44 are required to serve from 13 to 15 months in the armed forces. About 85,000 men and women serve in the Home Guard.

People

Ancestry. The Norwegians are a Scandinavian people closely related to the Danes and the Swedes. The Danes of Norway have strong ties with Americans. From the mid-1800s to the early 1900s, more than 9,000 Norwegians migrated to the United States in search of better job opportunities.

About 40,000 Sami, formerly known as Lapps, live in far northern Norway (see Sami). That region also has about 10,000 people of Finnish ancestry. Norway also has many immigrants. They include people from Iran, Pakistan, and Turkey, and from Africa, the United States, Southeast Asia, and from other European nations.

Language. The Norwegian language has two forms—Bokmål and Nynorsk. They are similar enough for someone who speaks either form to understand a person who speaks the other. Both Bokmål and Nynorsk belong to the Scandinavian group of Germanic languages. Local school boards may select either as the chief form in a school, but all students learn to read both. The Sami also use their own language, which is similar to Finnish.

Bokmål, also called Riksmål, is the major form used in the cities and towns, and in most Norwegian schools. Bokmål is a Norwegian form of Danish. It has almost the same vocabulary and spelling as Danish, but is pronounced much differently. Bokmål developed during Norway's political union with Denmark, which lasted from 1380 to 1814. During that period, it replaced Old Norse, the early Norwegian language.

Nynorsk, originally called Landsmål, was created during the mid-1800s as a reaction against the Danish influence. Nynorsk was based on the many dialects (local forms of speech) that developed in rural areas during Norway's union with Denmark.

Way of life

City life. About three-fourths of Norway's people live in urban areas. But Norway is less urban than Denmark and Sweden, where about four-fifths of the people live in cities. Oslo, Norway's capital and largest city, has about half a million people. Other large cities include Bergen, Drammen, Kristiansand, Stavanger, Tromso, and Trondheim. See the articles on Norwegian cities listed in the Related articles at the end of this article.

Norwegian cities sprawl into surrounding suburbs, but they are smaller than most other European cities. They have fewer high-rise commercial buildings and lack the fast pace of life often found in cities of other industrial nations.

Norway's high standard of living and its social welfare system have kept the cities free of slums and substandard housing. Most Norwegians and immigrant workers live in modern apartment buildings in or near the principal urban areas. Wealthier Norwegians often own single-family homes built of wood. A number of Norwegians also own small cottages along the coast or in the mountains, which they visit on weekends or holidays.

Although Norway's cities have bus and train services, traffic congestion is a problem. Norway has little industrial pollution because of its extensive use of hydroelectric power and natural gas in industry. Unemployment is extremely low by international standards. Many of Norway's immigrants work in low-paying jobs in the cities. Their presence has caused discontent among some Norwegians because of the benefits the immigrants get through the social welfare system.

Rural life. About a fourth of Norway's people live in rural areas. The rural population is concentrated in southeastern Norway, which has gently rolling hills suitable for farming, along the western coast, and in the northern regions. Many people who live in rural areas...
Norwegian fishermen process a catch of fish. The fishing industry provides a livelihood for many rural Norwegians.

in the cities and towns eat dinner in the evening. Some people in farm areas have dinner at midday.

Norwegians drink coffee throughout the day and especially at mealtimes. Many Norwegians also enjoy beer, which is sometimes served with a strong, colourless liquor called aquavit. Tea, milk, and soft drinks are also popular in Norway.

Recreation. Outdoor sports are an important part of Norwegian life. Recreation areas lie within short distances of all homes. Skiing, Norway's national sport, may have started there thousands of years ago as a means of crossing the snow-covered land. Many Norwegians take cross-country ski trips to the country's mountains or wooded hills. Almost every town has a ski jump. The second most popular winter activity is ice-skating. Norwegians also have long enjoyed bandy, a form of hockey played by 11-player teams on large rinks. Soccer is the favorite summer sport.

Norway's forests and mountains provide many other recreational opportunities. On weekends, many Norwegians enjoy hiking through hills and forest areas. Some Norwegians travel to cabins in the mountains, where
they may spend several weeks during the summer vacation season. Many adults also enjoy hunting. Sailing is popular along the coast. In addition, Norway’s numerous fjords, lakes, and rivers attract many fishing enthusiasts. Swimming is also a popular activity.

Social welfare. The government of Norway provides help people with many welfare services. All families with more than one child receive a yearly allowance for each youngster under the age of 16, beginning with the second one. These families also may receive financial aid in paying their rent. The government guarantees all employed people an annual four-week vacation with full pay. Large families with medium or low incomes pay little or no national taxes, and their local taxes are reduced.

The National Insurance Act, which went into effect in 1967, combined many existing welfare programs. All Norwegians are required to take part in this combined plan. It includes old-age pensions, job retraining, and aid for mothers, orphans, widows, widowers, and people with disabilities. Another insurance plan provides medical and hospital care, plus cash payments to employees during illness. The costs of these plans are shared by the insured people, their employers, and the national and local governments.

Religion. The Norwegian Constitution establishes the evangelical Lutheran Church as the nation’s official church, but other religions have complete freedom of worship. About 88 percent of the people are Evangelical Lutherans. The government largely controls the Evangelical Lutheran Church. It appoints the pastors and church officials and pays their salaries.

Other religious groups in Norway include Baptists, Free Lutherans, Methodists, Pentecostals, and Roman Catholics. The Oslo region is home to a large Muslim community.

Education. Almost all people in Norway can read and write. Norwegian law requires children from the age of 7 to 16 to go to school. The elementary school program lasts six years. It is followed by three years of junior high school and three years of senior high school. Senior high school provides academic courses for those who wish to go on to college and also vocational courses. Bergen, Oslo, Tromsø, and Trondheim each have a university. Schools of higher education also include a network of regional colleges, and several technical and other specialized institutions.

The University of Oslo Library is the largest library in Norway. Oslo also has the country’s largest city library. All cities and towns are required by law to have free public libraries. These libraries are partly supported by government grants.

Arts. Norwegians have contributed much to the development of the arts. Henrik Ibsen’s realistic plays of the late 1800’s brought him worldwide fame as the father of modern drama. Three Norwegian writers—Johannes Bjørnson, Knut Hamsun, and Sigrid Undset—have won the Nobel Prize for literature.

The painter Edvard Munch was a strong influence on the Expressionist art style of the early 1900’s. Statues by Gustav Vigeland, perhaps Norway’s greatest sculptor, stand in Oslo’s Frogner Park. Edvard Grieg, Norway’s best-known composer, used melodies from Norwegian folk songs and dances in his orchestral works. For more information on Norwegian artists, see the biographies listed in the Related articles at the end of this article.

The land

Land regions. Most of Norway is a high, mountainous plateau. Its average height is more than 1,500 feet (457 meters) above sea level. Only about a fifth of Norway, including two major lowlands, lies lower than 500 feet (150 meters). Norway has three main land regions: (1) the Mountainous Plateau, (2) the Southeastern Lowlands, and (3) the Trondelag Lowlands.

The Mountainous Plateau is covered largely by bare rock that was smoothed and rounded by ancient glaciers. Glaciers also formed many lakes and deep valleys, especially in the 4,500-square-mile (11,700-square-kilometer) Hardanger Plateau, Europe’s largest highland plain. In Norway’s uplands above 6,500 feet (1,980 meters), permanent snow and ice cover about 1,200 square miles (3,110 square kilometers). The 188-square-mile (487-square-kilometer) Jostedal Glacier is the largest ice field in Europe outside Iceland.

In the narrow northern half of Norway, the Kjølen mountain range extends along the border with Sweden. Norway’s highest mountains rise in the wider southern half of the country. The Dovre Mountains extend in an east-west direction, and the Long Mountains rise to the south. The Jotunheimen range of the Long Mountains includes Galdhopiggen, northern Europe’s tallest mountain, which rises 8,100 feet (2,469 meters).

The Southeastern Lowlands consist mostly of the middle and lower valleys of the Glåma River, which is 372 miles (598 kilometers) long, and several other rivers. The rivers are used to float timber to pulp mills and sawmills. Their many waterfalls provide hydroelectric energy. The region also has narrow lakes, including Lake Mjosa. Slopes are gentler than in most of the country, and the region is more suitable for farming and
forestry. These lowlands are the most thickly settled part of Norway. They include Oslo, the capital and chief commercial, industrial, and shipping center.

The Trondheim Lowlands include the lower ends of several wide, flat valleys. In addition to providing good farmland, the valleys also serve as important railroad routes to other parts of Norway and to Sweden.

The lowlands have long been a major region of settlement. Trondheim, founded in A.D. 998, was an important religious center in Norway during the Middle Ages. Today, it is a leading center of industry and trade.

Coast and islands. Many long, narrow inlets of the sea indent the rocky coast of Norway. These inlets, called fjords, make the coastline one of the most jagged in the world. The longest, Sogne Fjord, extends inland for 127 miles (204 kilometers). Norway has a coastline of about 1,667 miles (2,650 kilometers). Including all the fjords and peninsulas, the full length of the coast is about 13,267 miles (21,351 kilometers), which is approximately half the distance around the world.

About 150,000 islands lie off the Norwegian coast. Some are only rocky reefs called skerries, which shield the coastal waters from stormy seas. The Lofoten and Vesterålen islands are the largest offshore island groups. The waters around them have rich cod fisheries.

The famous Maelstrom current sweeps between the two outermost Lofotens, sometimes forming dangerous whirlpools. Jan Mayen and Svalbard are island possessions of Norway in the Arctic Ocean.

Climate

The climate of Norway is much milder than that of most other regions as far north, especially along the country's west coast. Near the Lofoten Islands, for example, January temperatures average 45 °F (25 °C) higher than the world average for that latitude. Snow that falls along the coast melts almost immediately. The warm North Atlantic Current of the Gulf Stream keeps nearly all the seas off ice-free, even in the Arctic (see Gulf Stream).

During winter, Norway's inland regions are colder than the coast because mountains block the warm west winds from the sea. Snow covers the ground at least three months a year. During the summer months, when the sea is cooler than the land, the west winds cool the coast more than the inland. The warmest summers are in the inland valleys of the southeast. Less rain falls inland than along the coast.

The far north, known as the Land of the Midnight Sun, has continuous daylight from mid-May through July.
period of midnight sun decreases southward, and there is no 24-hour sunshine south of the Arctic Circle. In winter, northern Norway has similar periods of continuous darkness. See Midnight sun.

Economy
Norway has a well-developed economy. In the last half of the 1900's, the nation's income from the production of goods and services increased sharply. Unemployment remained relatively low. The rapid economic growth resulted largely from government programs to promote investment and industries, and from increased foreign demand for the goods and services of Norway.

Natural resources. Norway's waters provide its most valuable resources. Important petroleum and natural gas fields lie offshore in the North Sea. The offshore areas and the country's rivers are rich in fish. Norway's many swift mountain rivers are used to produce hydroelectric power.

Norway's land is not rich in natural resources. About 60 percent of the country consists of mountains and plateaus that are covered mostly by bare rock. Only about 3 percent of Norway is farmland. Productive forests cover more than 20 percent of the land.

Service industries are those economic activities that provide services instead of producing goods. As in other industrial nations, Norway's service industries employ a growing number of workers. In the mid-1900's, employees in service industries accounted for about 45 percent of the work force. By the end of the 1900's, these activities employed close to 70 percent of Norway's workers.

Community, government, and personal services employ more than a third of Norway's workers and include such activities as education, health care, and government. Other service industries include banking, communication, insurance, trade, and transportation.

Mining became a major Norwegian economic activity during the 1970's, when the country began producing petroleum and natural gas from North Sea fields. Today, petroleum and natural gas account for a large part of the country's income. Iron ore and pyrites, from which copper and sulfur are taken, are mined in Norway. Other minerals include ilmenite, lead, molybdenite, and zinc. Coal is mined only in Svalbard, an island territory north of Norway.

Manufacturing developed much later in Norway than in the major industrial countries. Those countries had their own coal to provide power with which to run machines. In the 1800's, Norway had to import coal for its factories, which made manufacturing costly and held back its growth. By 1900, Norway had started to develop its sources of cheap hydroelectric power. The country's factories turned to hydroelectric power to meet their needs. As a result, manufacturing in Norway expanded rapidly.

Today, manufacturing is one of Norway's most valuable industries. The most important products include petroleum products, chemicals and chemical products, such metals as aluminum and magnesium, processed foods, and wood pulp and paper. Norway is an important aluminum-producing country. This metal is processed from imported bauxite. The nation also produces clothing, electrical machinery, furniture, and small ships.

Agriculture. Farms in Norway lie on narrow strips of land in inland valleys and along the coast. About two-thirds of the country's farms cover 25 acres (10 hectares) or less.

Many Norwegian farmers have a second occupation so they can earn enough to support their families. Farmers own about two-thirds of Norway's commercial forests, and many are also loggers. Some farmers also fish commercially.

Dairy farming and livestock production account for over two-thirds of Norway's farm income. Most crop land is used to grow livestock feed. The major crops of Norway are barley, fruits and vegetables, hay, oats, and potatoes.

Fishing. Norway has long been a great fishing country. Its total catch is about 4 billion pounds (1.8 billion kilograms) a year. Norwegian fishing crews bring in Norway's gross domestic product

Norway's gross domestic product (GDP) was $152,943,000,000 in 1999. The GDP is the total value of goods and services produced within a country in a year. Services include community, government, and personal services; finance, insurance, real estate, and business services; trade, restaurants, and hotels; and transportation and communication. Industry includes construction, manufacturing, mining, and utilities. Agriculture includes agriculture, forestry, and fishing.

Figures are for 1996.

Sources: Statistics Norway; International Monetary Fund.
Norway possesses rich petroleum and natural gas deposits in the North Sea. Exports of petroleum and natural gas have greatly stimulated Norway's economy.

large numbers of cod, haddock, herring, and mackerel. Much of the catch is processed for export. Norway's once-great whaling industry declined sharply during the 1960's. Large catches by Norway and other major whaling nations made many kinds of whales increasingly scarce. In 1987, Norway joined an international moratorium (temporary halt) on commercial whaling (see Whale). The future of whales. It continued to take some whales for research purposes. In 1993, Norway resumed limited commercial whaling of minke whales, claiming they were no longer in danger.

Forestry has been an important industry in Norway for hundreds of years. Lumber became a major export in the 1500's. Today, much timber is also used to make pulp and paper. Commercial trees include birch, pine, and spruce. More than 12,000 miles (19,300 kilometers) of forest roads have been built to transport the logs. Much timber is also moved by way of rivers.

Norwegian loggers cut more than 350 million cubic feet (10 million cubic meters) of timber a year. The forest growth rate is about 670 million cubic feet (19 million cubic meters) a year. Timber production could not be increased much without using up the forests, all of which are protected by government regulations.

Energy sources. Since the early 1900's, hydroelectric stations have generated most of the power used in Norway's industry and homes. But since the mid-1970's, the extraction of Norway's rich oil and natural gas deposits in the North Sea has led to more extensive use of petroleum products in industry and transportation. About half of the energy Norway consumes is now generated by hydroelectric power. About 40 percent of the country's energy is produced by petroleum products, and about 10 percent by such solid fuels as coal, peat, and wood.

Foreign trade. Norway depends heavily on foreign trade to help keep its standard of living high. The nation's trade is one of the largest in the world in relation to its population. Norway, with limited natural resources, imports a wide variety of foods and minerals as well as manufactured goods. Petroleum and natural gas rank as Norway's chief exports. Other exports include chemicals, fish, machinery, metals, transportation equipment, and wood pulp and paper. Norway's merchant fleet, one of the largest in the world, is also an important source of income for the country. The fleet provides shipping services for countries in all parts of the world.

Norway's leading trade partners are Sweden, Denmark, Germany, and the United Kingdom. Norway also trades with other European countries and the United States.

Transportation. Norway's merchant fleet ranks as one of the world's largest. Several hundred vessels link the coastal cities and towns of Norway. Inland, ferries cross many fiords and rivers.

Norway has an extensive road system. Almost all Norwegian households own an automobile. The world's longest highway tunnel, the Laerdal Tunnel, opened in 2000. It extends 15.2 miles (24.5 kilometers) under the Jotunheimen mountain range in southern Norway.

The government owns and operates nearly all the railroads. It also owns part of the Scandinavian Airlines System, which flies throughout the world. Several airlines provide regular service to all parts of Norway. The country's chief airports are located at Oslo, Bergen, Stavanger, and Trondheim.

Communication. Norway has about 80 daily newspapers. The most important dailies include the Aftenposten, Dagbladet, Dagsavisen, and Verdens Gang of Oslo; the Bergens Tidend of Bergen; and the Adressenvisen of Trondheim. Many of the country's newspapers support the views of one of the major political parties.

The government-owned Norwegian Broadcasting Corporation operates the national radio and television systems. No advertising is allowed on its programs. The corporation is funded by license fees on all television sets in the country. In 1992, Norway's first nationally broadcast commercial television station, TV2, began operating. Now there are several commercial television stations as well as local commercial radio stations. Norway has an average of 1 radio for every person and 1 television set for every 2 people.

The government owns and operates the telegraph system and most telephone services. Telegraph and telephone lines connect all sections of Norway.
Early days. Almost 11,000 years ago, people lived on the northern and western coasts of what is now Norway. Most of the region was covered by thick ice sheets, which took thousands of years to melt. By 2000 B.C., people had started to settle there permanently. By the time of Christ, Germanic tribes had spread throughout the region, and they continued to arrive for hundreds of years. These tribes formed local and regional communities ruled by chiefs and kings.

The Viking period. Viking sea raiders from the Norwegian communities spread terror through much of eastern Europe for about 300 years. Beginning with the defeat of Britain and Ireland in A.D. 793, they attacked pastal towns and sailed away with slaves and treasure. They also sailed to the west and established colonies in the Faroe Islands and other North Atlantic islands. About 870, they explored farther west and colonized Iceland. Eric the Red brought the first group of settlers to Greenland about 985. About 1000, his son, Leif Ericson, led what is believed to have been the first voyage of Europeans to the mainland of America. See Eric the Red: Ericson, Leif: Vikings (The Norwegian Vikings).

About 900, much of present-day Norway was united under Norway's first king, Harold I (called Fairhair), or earl I. He defeated many local chieftains and other leaders recognized his leadership. King Olav I Tryggvason began the widespread conversion of Norway to Christianity in the 990's. In the early 1000's, Olav II achieved full Norwegian unity and firmly established Christianity. He became recognized as Norway's patron saint soon after his death in 1030.

The Viking period ended around 1100. The church re-won in power, foreign trade expanded, and religious and trading centers became important cities. Political collusion and bitter struggles for royal power also developed. Beginning in 1130, many regional leaders claimed the throne. They were defeated in a series of civil wars that lasted until 1240. Peace was restored under Haakon IV. By 1300, Norway's economy was largely controlled by the English merchants. Norwegians became dependent on them for grain imports. As weakened further in 1349 and 1350, when about all of its people died in an epidemic of plague.

Union with Denmark. Margaret, the wife of King Haakon VI of Norway, was also the daughter of the king of Denmark. After her father died in 1375, she had her young son elected king and she ruled Denmark as regent. Haakon died in 1380, and Margaret became regent of Norway as well. In 1388, during political confusion in Denmark, Swedish noblemen elected her to rule that country, too. In 1397, in the Union of Kalmar, Margaret united Norway, Denmark, and Sweden, with power centered in Denmark. Sweden revolted against Danish rule several times, and broke away from the union in 1523.

Under the Danish-controlled union, Norway grew weaker and Denmark became stronger. In 1536, Denmark declared Norway a Danish province and made Lutheranism the official Norwegian religion. Although Danish law acknowledged Norway as a separate kingdom in 1665, the monarch of Denmark continued to rule Norway. During the 1500's, Norway exported increasing amounts of lumber to the countries of western Europe. As a result, Norway began to develop a great shipping industry during the late 1600's. The industry expanded rapidly throughout the 1700's.

Union with Sweden. In 1807, during the Napoleonic Wars, Denmark sided with France against the United Kingdom. The United Kingdom had been Norway's chief trading partner, but now the British ended the trade. British warships blockaded Norway's trade with other countries, and many Norwegians starved. Norway was cut off from Denmark by the British blockade and began to manage its own affairs. The Norwegians secretly began to trade with the British again.

Denmark was defeated in 1813 by Sweden, an ally of the United Kingdom against France. In 1814, in the Treaty of Kiel, Denmark gave Norway to Sweden. Denmark kept Norway's island colonies—Greenland, Iceland, and the Faroe Islands.

Important dates in Norway

- c. 870 Norwegian Vikings colonized Iceland.
- c. 900 Harold I united Norway.
- c. 985 Eric the Red colonized Greenland.
- c. 1000 Leif Ericson sailed to North America.
- 1349-1350 An epidemic of plague killed about half the people of Norway.
- 1380 Norway was united with Denmark.
- 1536 Norway became a Danish province. Lutheranism was made Norway's official religion.
- 1814 Denmark gave up Norway to Sweden but kept Norway's island colonies.
- 1884 The cabinet of Norway became responsible to the parliament instead of the king.
- 1905 Norway became independent.
- 1940-1945 German troops occupied Norway in World War II.
- 1945 Norway joined the United Nations.
- 1949 Norway became a member of the North Atlantic Treaty Organization.
- 1957 King Haakon VII died and was succeeded by Olav V.
- 1960 Norway and six other nations formed the European Free Trade Association.
- 1967 Norway began its greatest welfare program, which combined many established social security plans under the National Insurance Act.
- 1970's Norway began producing petroleum and natural gas from North Sea fields, greatly stimulating the economy.
- 1991 King Olav V died and was succeeded by Harald V.

Norwegian Vikings sailed long wooden ships—like this one preserved in an Oslo museum—in raids along the coast of western Europe. They also explored the North Atlantic Ocean.
The Norwegians did not recognize the Treaty of Kiel. Later in 1814, they elected an assembly to draw up a constitution for an independent Norway. The constitution was adopted on May 17, but Sweden refused to grant Norway independence. Swedish forces attacked Norwegian troops and quickly defeated them. In November 1814, the Norwegian parliament accepted King Charles XIII of Sweden as Norway's ruler as well. Charles promised to respect the Norwegian constitution.

In 1884, after a long political struggle, the parliament won the right to force the cabinet to resign. Until that time the cabinet had been responsible only to the king. Independence. During the 1890s, Norway's merchant fleet was one of the largest in the world. But the Swedish foreign service handled Norway's shipping affairs in overseas trading centers. Norway demanded its own foreign service, but Sweden refused. In May 1905, the Norwegian parliament passed a law creating a foreign service, but the Swedish king vetoed it. On June 7, the parliament ended the union with Sweden.

Sweden nearly went to war against Norway. However, Sweden recognized Norway's independence in September 1905, after all but 184 Norwegians voted for independence. In November, the people approved a Danish prince as their king. He became Haakon VII.

By the time of independence, Norway had started to develop its many mountain streams to produce hydroelectric power. Its industries expanded rapidly with this cheap power source. Norway's economy increased further during World War I (1914-1918). Norway remained neutral, but its merchant fleet carried much cargo for the Allies. About half its ships were sunk by German submarines and mines.

An economic depression hit Norway following the end of World War I. The nation's economy, dependent on trade and shipping, suffered further during the worldwide depression of the 1930s. Between a fourth and a third of Norway's workers were usually unemployed during this period.

World War II began in 1939, and Norway tried to remain neutral. But on April 9, 1940, Germany invaded Norway by attacking all its main seaports at once. The Norwegians fought bravely for two months, aided by some British, French, and Polish troops. On June 7 of that year, King Haakon VII and the Cabinet fled to London where they formed a government-in-exile. The Germans made Vidkun Quisling, a Norwegian who supported them, premier of Norway. His last name became an international word for traitor.

A secret Norwegian resistance army conducted sabotage against the German occupation force. These Norwegians were trained chiefly to join a hoped-for Allied invasion of Norway. Other Norwegians fled their country and trained in Sweden or the United Kingdom for the invasion. Some took part in British commando raids in Norway. After each raid, the Germans shot, tortured, or imprisoned many Norwegians.

Norwegian fighter pilots trained in Canada, and operated from bases in the United Kingdom and Iceland. Norway's merchant fleet carried war supplies for the Allies. The Norwegian navy helped protect Allied shipping, and took part in the invasion of France in 1944.

On May 8, 1945, after Germany fell, the 350,000 German troops in Norway surrendered. Haakon VII returned in triumph on June 7, the 40th anniversary of Norwegian independence. About 10,000 Norwegians died during the war, and about half the merchant fleet was sunk. The far northern counties of Finnmark and Troms lay largely in ruins. See World War II.

Postwar developments. After the war, loans from the United States helped Norway rebuild its merchant fleet and industries. By the late 1950s, the Norwegian economy was thriving.

Norway became a charter member of the United Nations in 1945. The next year, Trygve Lie of Norway became the first secretary-general of the UN. In 1949, Norway became a charter member of the North Atlantic Treaty Organization (NATO). But Norway refused to per-
mit NATO bases or nuclear weapons on its territory for fear of angering the Soviet Union, its neighbor on the northeast. (The Soviet Union had been formed under Russia’s leadership in 1922, and it existed until 1991). In 1960, Norway and six other countries formed the European Free Trade Association, an economic union (see European Free Trade Association).

In 1957, Haakon VII died. His son became King Olav V of Norway.

**Social and economic changes.** In 1966, the parliament passed the National Insurance Act. The program combined such social security plans as old-age pensions, job retraining, and aid for mothers, orphans, widows, widowers, and disabled people. The Norwegians based much of their expanded social welfare program on the Swedish system, which provided many benefits. In 1972, Norway signed a preliminary treaty to join the European Community, an economic organization of European nations. The treaty was submitted for voter approval. Supporters argued that membership would benefit the Norwegian economy, while opponents feared that it would threaten Norway’s national identity and quality of life. In September 1972, Norway’s voters rejected the membership treaty. The Norwegian government then reached a more limited agreement with the European Community to eliminate tariffs on most industrial goods.

Norway began producing petroleum and natural gas from North Sea fields during the early 1970’s. The extraction and processing of petroleum and gas greatly stimulated economic growth. Because of its increased petroleum exports, Norway profited from large increases in the price of oil from the mid-1970’s to the early 1980’s. During this period, the country’s economy continued to expand and unemployment remained low, while many other nations struggled with inflation and slow economic growth. However, during the late 1980’s, a decline in the international price of petroleum resulted in a slowing of Norway’s economic growth.

**Political changes.** After decades of socialist Labor Party dominance in the Cabinet, Norway entered a period of rapidly shifting coalitions and governments during the 1980’s. Since then, coalition governments, usually led by either the Labor Party or the Conservative Party, have ruled the country.

In 1981, Gro Harlem Brundtland became the first woman to serve as Norway’s prime minister. Although her first term lasted less than a year, she held the post again from 1986 to 1989 and from 1990 to 1996. Until 1990, only a king could serve as monarch of Norway. That year, the Storting amended the Constitution to allow women to inherit the throne. Olav V died in 1991. His son, Prince Harald, succeeded him as King Harald V.

**Recent developments.** In the 1990’s, the European Community grew into the European Union (EU), an organization that promotes political and economic cooperation among member states. In 1992, the Storting voted to join the European Economic Area, which provided some of the benefits of EU membership. Many Norwegians urged that the country join the EU. But in November 1994, Norwegians voted against this.

In 1993, Norway fostered peace negotiations between Israel and the Palestine Liberation Organization, which led to the Oslo accords. In 2000, Norway began helping in peace negotiations between Sri Lanka’s government and that country’s Tamil rebels.
Norwegian elkhound

Norwegian elkhound is a hunting dog that originated in Norway, probably between 5000 and 4000 B.C. Hunters claim the elkhound can scent an elk 3 miles (5 kilometers) away. The elkhound stalks its prey quietly and holds it at bay until the hunter arrives. It is also used in hunting bear and game birds. The elkhound's coat is thick and gray with black tips. The dog weighs about 50 pounds (23 kilograms).

Critically reviewed by the Norwegian Elkhound Association of America

See also Dog (picture: Hounds).

Norwich terrier is a breed of dog that developed in England about 1880. Norwich terriers are alert, quick, sturdy, and instinctively good at hunting mice, rats, and other small animal pests. They make good pets as long as they get plenty of exercise and attention.

Norwich terriers are very similar to Norfolk terriers. But the ears of Norwich terriers stand erect, and those of Norfolk terriers drop forward. The Kennel Club in

The Norwich terrier originated in England.

England recognized the dogs as separate breeds in 1964. The American Kennel Club recognized them as different breeds in 1979. See Norfolk terrier.

Norwich terriers may be any shade of red, or black and tan. They have a straight, wiry outer coat and a harsh undercoat. The dogs have short, sturdy legs, and sometimes their tail is docked (cut) to 3 to 4 inches (8 to 10 centimeters) in length. Full-grown Norwich terriers stand approximately 10 inches (25 centimeters) high at the shoulder and weigh from 10 to 12 pounds (4.5 to 5.4 kilograms).

Critically reviewed by the Norwich and Norfolk Terrier Club

Nose is the organ used for breathing and smelling. It forms part of the face, just above the mouth. Outwardly, it seems simple, but it is complicated inside.

When we breathe, air enters the nose through two openings called nostrils. The nostrils are separated by the septum, a thin wall of cartilage (tough tissue) and bones. Air passes from the nostrils into two tunnels called the nasal passages, which lead back to the upper part of the throat. From the nasal passages, air passes through the pharynx and trachea into the lungs.

Both nasal passages have a lining of soft, moist mucous membrane covered with microscopic, hairlike projections called cilia. The cilia wave back and forth constantly, moving dust, bacteria, and fluids from the nose to the throat for swallowing. Each nasal passage also has three large, shelllike bones that are called turbinates or conchae. The top two turbinate bones on each side are actually processes (extensions) of the ethmoid bone. The lowest turbinate bone on each side is a separate bone. The turbinates warm the air before it enters the lungs. These bones also stir up the air so that dust in the air sticks to the mucous membrane of the turbinates and does not pass into the lungs.

The perception of smell occurs in the highest part of the nasal cavity, where olfactory nerve receptors lie in a small piece of mucous membrane about as big as a
time. These receptors generate nerve impulses in response to chemicals in the air. Olfactory nerve fibers then carry the impulses to a part of the brain called the olfactory bulb. One olfactory bulb lies just above each nasal passage. From there, the impulses are carried to other parts of the brain, where they are translated into sensations of odor.

The sense of smell is closely related to the sense of taste. Some experts believe that much of our taste sensations are really sensations of odor that we have associated with certain tastes. For example, we really smell coffee, tobacco, wine, apples, and potatoes more than we taste them. If a person is blindfolded and the nose stopped up so that the person cannot smell, the person has great difficulty telling apples from potatoes by taste. Red wine and plain coffee taste almost alike to such a person when they are at the same temperature and consistency.

We cannot smell when we have a cold, because the infection inflames the mucous membrane of the nasal passages and blocks the passage of air to the center of smell. It is important to keep nasal passages clean and to treat any inflammation of the mucous membrane at once. When neglected, colds can lead to more serious ailments, such as bronchitis and pneumonia. Sinuses, which empty into the nose, may also become infected.

- Mucus
- Rhinitis
- Sinus
- Nasal passages
- Respiration
- Nosebleed
- Smell (with diagram)
- Cold sore (with diagram)

**Nosebleed** is a discharge of blood from the nose. Most nosebleeds result from minor irritations of the tissue that lines the lower nasal passages. But nosebleeds may also occur as a symptom of a serious illness or as the result of a head or neck injury. The medical term for nosebleed is *epistaxis*.

The nasal passages are lined with a thin, moist tissue called the *mucous membrane*. Many small vessels carry blood close to the membrane’s surface. If the membrane becomes dry, even slight knocks or scratches can break the blood vessels. This type of nosebleed commonly occurs in the winter, when nasal tissues become irritated by dry, cool air and by colds and influenza.

Minor nosebleeds frequently result from irritations of the mucous membrane that covers the *nasal septum*, the structure that separates the two nostrils. Some people have a *deviated septum*, which curves into one of the two nostril chambers. A deviated septum lies directly in the path of air entering the nose, and therefore is likely to become dried and to bleed if irritated.

To stop a minor nosebleed, sit down and lean forward, with your chin toward your chest. Then, pinch your nostrils together for about 10 minutes. If bleeding cannot be controlled, seek medical attention.

To stop a minor nosebleed, sit down and lean forward, with your chin toward your chest. Then, pinch your nostrils together for about 10 minutes, or until the bleeding stops. If the nosebleed does not stop after using these measures, seek medical attention.

Severe nosebleeds may be a symptom of a blood-clotting disorder, leukemia, or the rupture of a large blood vessel at the back of the nose. Heavy bleeding from the nose may be life-threatening and thus requires emergency medical care. If a head or neck injury is suspected, do not move the person. Prevent the head and neck from moving by stabilizing them with your hands. Have someone call for an ambulance immediately.

David D. Caldarelli  Critically reviewed by the American Red Cross
Nostradamus, naiz truh DAY truh (1503-1566), was the Latin name of Michel de Notredame, a French astrologer and physician. His fame rests on his book Centuries (1555), a series of prophecies in verse. Nostradamus won lasting fame in 1559 when King Henry II of France died in a manner predicted in the Centuries.

Nostradamus was born in St.-Rémy, in southern France. He earned a doctor's degree in 1532, and became a professor at the University of Montpellier. The success of Centuries gained him an appointment as court physician to King Charles IX of France. He also became an adviser to Catherine de Médicis, wife of King Henry II of France.

Nostradamus' prophecies are vague and open to interpretation. One published in 1921 seemed to predict World War II (1939-1945). During that war, the Nazis issued their own versions of Nostradamus' prophecies to convince the German people and their European enemies of the Nazis' ultimate victory. John Bell Henneman

Nostril. See Nose.

Notary public, noh TAY shuhn, is an officer authorized by state law to certify certain documents and to take oaths. Many documents, such as deeds, must be notarized before they become legally effective. The purpose of notarizing a document is to protect those who use it from forgeries. The notary signs the document to certify that the individual who signed it appeared in person and swore to the notary that the signature on the document is genuine. The notary records that fact, then stamps a seal on the document.

In many states, any responsible person can get a commission as a notary public, on payment of a fee. Notaries are usually allowed to charge for their services. In Great Britain and Canada, the Court of Faculties appoints notaries.

Jack M. Kress

Notation, noh TAY shuhn, is any system of symbols and abbreviations that helps people work with a particular subject. Mathematics uses notation to simplify and consolidate ideas and problems. The Arabic numeral system is a notational device for writing numbers and making arithmetic easier. Chemistry, music, physics, and other subjects have also developed notation systems. See also Arabic numerals; Numeration systems; Music (Musical notation); Symbol.

Howard W. Eves

Note is an unconditional written promise to pay a specified sum of money on demand or at a given date to a designated person. The one who signs the note is called the maker. The one to whom it is made payable is called the payee. This written promise is called a promissory note. Note of hand is a name sometimes used for a promissory note.

Suppose that Arlene Shaw, a retail merchant with a good business and a good financial standing, needs $500 worth of merchandise but does not have the cash to pay for it. She knows that she has accounts coming due within 60 days. She will be able to pay the $500 when she is paid by those who owe her. She goes to Henry Brown, a wholesale merchant, who sells her the goods and takes her note. The note is as follows:

$500
San Francisco, Calif.
March 1, 1991
Sixty days after date I promise to pay to the order of Henry Brown $500, with interest at 10 per cent. Value received.

Arlene Shaw

Brown can endorse the note and cash it at the bank, if he needs the money before 60 days. Shaw will then pay the bank when her note becomes due. Sometimes the maker specifies the actual date of payment in the note.

Liability of the maker. A note is negotiable when it is made payable to "bearer" or includes the word "order," like the one given above. When a note has been transferred by endorsement, the person in possession of the note is known as the holder. The holder can transfer it to another by endorsing it, and so on indefinitely, just as a bank check can be transferred. When the note falls due, the holder looks to the maker for payment. The law protects the holder under almost all conditions, including some kinds of fraud or cheating by the payee.

An endorser is liable in case the maker fails to pay the note when it falls due. The endorser is served with a notice called a protest. It is signed by a notary public, and one copy is sent to each endorser if there is more than one (see Notary public).

Caution. No one should sign a document without fully understanding what is being signed. A lawyer should examine any document that the maker does not understand. The law holds the maker responsible for his or her signature, except when any part, or all, of the document is proved fraudulent in court, or is proved to have been altered without the maker's knowledge, after it was signed in good faith.

Joanna H. Frodin

Notre Dame, noh TAY DAHM. Cathedral of, is a famous cathedral in Paris. It stands on the Île de la Cité, a small island in the Seine River, in the center of Paris. The cathedral is dedicated to Notre Dame, the French expression for Our Lady, the Virgin Mary. The cathedral is one of the finest examples of Gothic architecture.

The cathedral stands on the site of two earlier churches. Construction of the present building occurred between 1163 and 1250. During the French Revolution in the late 1700s, Notre Dame was heavily damaged by mobs who regarded the church as a symbol of the hated monarchy. Beginning in 1845, the French architect Eugène Emmanuel Viollet-le-Duc directed extensive restorations of Notre Dame. He was responsible for much of the cathedral's present appearance.

Notre Dame was one of the first buildings to have flying buttresses (arched exterior supports). The buttresses strengthen the walls and permit the use of large stained-
The Cathedral of Notre Dame is a masterpiece of Gothic architecture and one of the most famous buildings in Europe. It stands on a small island in the Seine River in the heart of Paris. The cathedral was built between 1163 and 1250. This picture shows the main entrance.

glass windows that allow light to enter the building. The cathedral's main entrances are elaborately decorated with stone sculptures. A number of other cathedrals are also named Notre Dame, including those in Amiens, Chartres, and Reims, France.

Notre Dame University is a coeducational Roman Catholic school in Notre Dame, near South Bend, Ind. It is governed by a board of trustees consisting of 35 lay people, and 7 priests of the Congregation of Holy Cross—the order that founded the university. Students of all faiths may attend Notre Dame.

The campus. Notre Dame has a 1,250-acre (506-hectare) campus, with twin lakes and wooded areas that provide a beautiful setting for more than 90 buildings. Landmarks include the Log Chapel, which is a replica of the first building erected at Notre Dame; and the Grotto of Our Lady of Lourdes, which is a replica of a shrine at Lourdes, France.

The 14-story Memorial Library, completed in 1963, has a capacity of about 2 million volumes. Nearly a third of the university's undergraduates can study there at one time. The library's important collections include the Dante Library of books from the early 1500's; the Hiberniana collection of Irish history and literature; the Kirsch-Wenninger-Hewland Biology Library; and the Zahm South American Library.

Bordering the campus is Notre Dame Stadium, where the 'Fighting Irish' football team plays. Great football figures, such as coach Knute Rockne, George Gipp, and the Four Horsemen of Notre Dame, brought the university much fame (see Rockne, Knute).

Educational program. Notre Dame's undergraduate school has colleges of arts and letters, business administration, engineering, and science. Courses in these colleges lead to bachelor's degrees. The College of Business Administration also grants the master's degree. Notre Dame's law school, the first law school at a Roman Catholic university in the United States, offers the Doctor of Laws degree. The graduate school at Notre Dame offers advanced degrees in 30 departments.

The university has awarded the Laetare Medal each year since 1883. The award honors a leading Roman Catholic of the United States for his or her contributions to society.

Research program. Notre Dame places a strong emphasis on research. It receives more than $20 million in
grants annually for research. The Center for Gerontological Education, Research, and Services investigates the aging process in human beings. The university also conducts research in radiation chemistry at a radiation laboratory built by the U.S. Atomic Energy Commission.

The Medieval Institute conducts research in the culture, life, and thought of the Middle Ages. Other research centers include the Institute for International Peace Studies and the Center for Bioengineering and Pollution Control. The university conducts research in a variety of other areas, including microelectronics materials science and the economics of developing countries.

Notre Dame was founded in 1842. Critically reviewed by the University of Notre Dame

See also Hesburgh, Theodore Martin.

Nottingham, NAHT ihng uhm or NAHT ihng HAM, is an industrial city in central England. It is the chief city and administrative center of the county of Nottinghamshire. Nottingham lies on the north bank of the River Trent (see England [political map]). The district of Nottingham, which includes the city and some surrounding areas, has a population of 279,400.

An old castle towers above the center of Nottingham. Other major landmarks include the University of Nottingham and St. Mary's Church, which is a good example of English church architecture of the 1400's. Sherwood Forest, near Nottingham, was supposedly the home of the legendary English outlaw Robin Hood (see Robin Hood).

Nottingham existed by the 800's and became a major center of the wool trade during the Middle Ages. During the late 1700's and early 1800's, the city prospered and its population increased rapidly as a result of the development of hosiery, knitting, and lacemaking industries there. Factories built during the late 1800's and early 1900's manufacture such products as bicycles, cigarettes, and pharmaceutical goods. G. Malcolm Lewis

Nouakchott, nwahk SHAHT (pop. 350,000), is the capital and largest city of Mauritania. It lies in western Mauritania, along the Atlantic Ocean. For location, see Mauritania (map).

The library at Notre Dame is the tallest building on campus and one of the largest university library buildings in the world. The 14-story building, built at a cost of $12 million, seats 2,900. The exterior features a mural, 132 feet (40 meters) high, made of 7,000 granite pieces. The mural depicts Christ, the apostles, and various scholars.

Government buildings and foreign embassies dominate the center of the city. Nouakchott is overcrowded. Severe droughts during the 1970's and 1980's forced large numbers of rural people to move to the city to obtain food and work. Many of them live in shacks and tents. Nouakchott has some modern housing. Its products include hand-woven woolen carpets and other handicrafts, soft drinks, and chemical products.

Nouakchott was founded in 1957, when France ruled Mauritania. It was established to replace St-Louis, Senegal, as the seat of Mauritania's colonial administration. It became the capital when Mauritania gained independence from France in 1960. Clement Henry Moore

Noun is a part of speech that identifies people, places, objects, actions, qualities, and ideas. The English language has a great variety of nouns. These nouns have been grouped into several classifications, some of which overlap.

Mass nouns and count nouns. Mass nouns identify things that cannot be divided into separate units, such as fruit and soil. Count nouns identify things that can be divided into units, such as apple and rose.

Mass nouns and count nouns do not differ completely because some words may belong to either group. In the sentence I bought cheese, for example, cheese is a mass noun. But in the sentence I bought the cheeses, cheese is a count noun. Count nouns, but not mass nouns, occur in the plural and with articles a, an, the. When what is ordinarily a mass noun is used as a count noun, it generally refers to a specific type, as in specific types of cheese.

Abstract and concrete nouns. Abstract nouns identify ideas and qualities that have no physical existence. Bravery, effort, and knowledge are abstract nouns. In contrast, concrete nouns identify objects that can be seen, heard, smelled, touched, or tasted. Airplane, layer cake, and skyscraper are concrete nouns. Some words can be used as either abstract or concrete nouns. Red as an abstract noun may specify the quality of redness. As a concrete noun, it may represent the color.

Abstract nouns usually function as mass nouns do.
Proper nouns are not proper nouns. They identify general categories of things, such as experiment, helper, holiday, and river. Collective nouns identify groups of persons, animals, or things. Examples include audience, class, crowd, family, flock, government, and team. A collective noun may be considered singular if the word is used as a unit. In this instance, the noun takes a singular verb. For example, The cast of the play was at its best. A collective noun is considered plural if the word is used in the sense of its parts. The noun then takes a plural verb—The cast were applauded loudly for their performances.

Nominals are words and phrases that function as nouns. Pronouns are the most common nominals, but other parts of speech may be used as nouns:

Adjective: The strongest was not best.
Gerund: Clam digging is fun.
Infinitive: To err is human.
Prepositions: We knew the ins and outs.
Pronoun: He took a walk.

Number and case. English nouns may have endings that show number and case.

Number is the form which indicates that the noun refers to one (singular) or to more than one (plural). Singular nouns indicate one, such as pear, apple, man, and mouse. Plural forms for these nouns are pears, apples, men, and mice. Abstract nouns, mass nouns, and proper nouns do not ordinarily have distinct plural forms. In special cases, these may be used as count nouns and ake plural, as in There are three Sams in this room.

Case is the form that helps show the relation of a noun to other words in a sentence. In some languages, words have many different endings to show relationships. In English, word order, rather than endings, shows relationships. Modern English nouns have only two cases, common case and possessive case. Boys, man, and Sam are common-case forms. Boys’, man’s, and Sam’s are possessive-case forms.

Gender. In English, nouns are sometimes said to have gender, but this is not regularly shown by endings. An English noun has gender only in the sense that it is referred to by one of three sets of pronouns: he or him, she or her, or it. For example, I found Jim and brought him home. I found Sally and brought her home: and I found a book and brought it home.

Nouns for which the corresponding pronoun is he or him are masculine nouns. Nouns for which the corresponding pronoun is she or her are feminine nouns. Nouns for which the corresponding pronoun is it are neuter nouns. Usually, masculine nouns name males, feminine nouns name females, and neuter nouns name animate or sexless things. However, there are some exceptions. Some people refer to ships as she, though most authorities prefer it. Babies are often referred to as it, except where the sex is known. Even when the sex is known, it is more common for many animals. In many languages, the relationship between gender and natural sex is not as close as it is in English. For example, learners of German must memorize noun genders.

There is a tendency in modern English to stop using special words for women. Some pairs are still common, such as actor and actress, but words like avatrix for a female aviator are virtually obsolete.

Sentence (Subject and predicate)

Nova is an explosion that causes a star to become from 10,000 to 100,000 times as bright as the sun. The star may shine this brightly for a month or longer before gradually fading to its original brightness. A nova hurls huge masses of gas and dust into space. The word nova comes from the Latin word for new. People once mistook novae for new stars.

Stars that undergo fast novae reach their maximum brightness several hours after the explosion. They begin to fade after a few days. Stars that undergo slow novae take much longer to reach their maximum brightness. However, they stay extremely bright for months or even years before they fade to their original brightness. Fast novae propel gas and dust outward at speeds of a few thousand miles or kilometers per second. Slow novae do so about a tenth as fast.

Astronomers believe that novae occur in close binaries. A close binary is a double star system in which two stars revolve closely around each other (see Binary star). For a nova to occur, one of the stars must be medium-sized, and the other must be a small, extremely dense star called a white dwarf. The two stars are so close that the gravitational pull of the white dwarf draws material rich in hydrogen from the larger star. This material collects on the white dwarf and eventually triggers reactions of nuclear fusion there. In such reactions, hydrogen nuclei combine to form helium nuclei, and a large amount of energy is released. The reactions quickly become a runaway process, which results in a nova.

During the last 100 years, astronomers have observed some stars that have undergone more than one nova. Astronomers call such explosions recurrent novae. All novae may be recurrent, but for some of them the interval between explosions may be hundreds or even thousands of years. This much time may be required for a white dwarf to accumulate enough hydrogen for nuclear fusion to recur. On the other hand, the causes of recurrent and ordinary novae may differ, and ordinary novae may occur only once in a close binary.

Some close binaries undergo small explosions every month or so. These dwarf novae do not throw out material during an outburst, and they become only 10 to 100 times as bright as the sun. Their cause is unknown. Other stars undergo explosions called supernovae, which are thousands of times as bright as ordinary novae. Some supernovae occur in binaries, while other result from the collapse of extremely massive stars.

Sumner Starrfield

Nova Scotia

Nova Scotia, NOH vuh SKOH shuh, is one of the four Atlantic Provinces of Canada. It includes a peninsula of the Canadian mainland and also Cape Breton Island. The province juts out into the Atlantic Ocean from the Canadian mainland. Each year, many visitors enjoy Nova Scotia’s beaches and coastal resorts.

No part of Nova Scotia is more than 35 miles (56 kilometers) from the sea. The Atlantic Ocean, the Gulf of St. Lawrence, and the Bay of Fundy almost surround the province. Only a narrow strip of land—the Isthmus of Chignecto—joins the peninsula to the Canadian mainland. Ocean tides may rise higher in Nova Scotia than anywhere else in the world. Sometimes the tide rises more than 50 feet (15 meters) at the head of the Bay of Fundy. Sable Island, which is formed entirely of sand, lies about 100 miles (160 kilometers) offshore toward the southeast. Sailors call Sable Island the Graveyard of the Atlantic because it has been the scene of many shipwrecks.

The sea keeps the climate of Nova Scotia from becoming either extremely hot or extremely cold. Thick forests cover much of the province. In the north, ranges of low hills stretch across parts of Nova Scotia. Seawater reaches far inland in many rivers that irrigate the rich soil of lowland farms. The Annapolis Valley, famous for its apple orchards, glows with pink and white apple blossoms in spring.

White-tailed deer roam the wilderness areas. Many kinds of sea birds nest along the shore and on offshore islands. Lobsters, scallops, and other seafood caught off Nova Scotia help make the province one of the leaders in the Canadian fishing industry.

Service industries are the leading economic activity in Nova Scotia. These industries include education, government, and hotels and restaurants. Manufacturing is also important to the province’s economy. The leading products include food products, paper products, transportation equipment, and printed materials. Nova Scotia leads the provinces in mining gypsum.

People have lived in the Nova Scotia region for about 10,000 years. A series of Native American cultures existed in the region before European explorers arrived in the early 1500’s. French settlement began at Port Royal.

The contributors of this article are Hugh Milward, Professor of Geography at St. Mary’s University, and D. A. Sutherland, Associate Professor of History at Dalhousie University.
Britain won control of Nova Scotia in the mid-1700's. The Latin words Nova Scotia mean New Scotland.

The American poet Henry Wadsworth Longfellow made Nova Scotia famous in his poem Evangeline. This partly fictional poem tells how French colonists, called Acadians, were driven from their homes in Nova Scotia by British troops. The poem gave part of the province the nickname Land of Evangeline.

In the early 1750's, settlers from Britain and other parts of Western Europe began coming to Nova Scotia in increasing numbers. During and after the Revolutionary War in America (1775-1783), many people who remained loyal to Britain fled from the United States to Nova Scotia. By the 1820's, people had begun to refer to Nova Scotians as "bluenosers," a nickname that probably came from locally-grown blue potatoes. Today, Nova Scotians still call themselves "Bluenosers."

Nova Scotia, along with New Brunswick, Ontario, and Quebec, was one of the four original Canadian provinces. These four formed the Dominion of Canada in 1867. For the relationship of Nova Scotia to other provinces, see Atlantic Provinces; Canada; Canada, Government of; Canada, History of.
Nova Scotia in brief

Symbols of Nova Scotia
The provincial flag, first authorized by a royal grant in 1625, bears the cross of St. Andrew and the arms of Scotland. These symbols show the province’s historical ties to Scotland. The provincial coat of arms, also granted in 1625, has the same symbols on a shield in the center. The Indian represents the province’s original inhabitants. A royal unicorn symbolizes England.

General information
Entered the Dominion: July 1, 1867; one of the original four provinces.
Provincial abbreviation: NS (postal).
Provincial motto: Munit Haec et Altera Vincit (One Defends and the Other Conquers).

Land and climate
Area: 21,423 mi² (55,490 km²), including 1,023 mi² (2,650 km²) of inland water.
Elevation: Highest—1,747 ft (532 m) above sea level in Cape Breton Highlands National Park. Lowest—sea level.
Coastline: 4,709 mi (7,579 km).
Record high temperature: 101 °F (38 °C) at Collegeville, near Antigonish, on Aug. 19, 1935.
Record low temperature: -42 °F (-41 °C) at Upper Stewiacke on Jan. 31, 1920.
Average July temperature: 64 °F (18 °C).
Average January temperature: 23 °F (-5 °C).
Average yearly precipitation: 53 in (134 cm).

Important dates
1497-1524: European explorers reached Nova Scotia while seeking a sea route to Asia.
1605: Samuel de Champlain and Pierre du Gua, Sieur de Monts, founded Port Royal.
1625: Provincial flag and coat of arms authorized.
1755: France gave Britain territory, including all of Nova Scotia except Cape Breton Island, under the Peace of Utrecht.
1713: British colonial troops from New England began to drive French Acadians out of Nova Scotia.
1719-1721: Maritime Provinces, including Nova Scotia, were united to Britain.
1749: Province House was established as the provincial capital.
Provincial coat of arms

Provincial seal

Floral emblem: Trailing arbutus

People
Population: 908,007 (2001 census)
Rank among the provinces: 7th

Economy

Chief products:
Agriculture: milk, hogs, chickens.
Fishing industry: lobster, scallops, herring, shrimp, crab.
Manufacturing: food products, paper products, tires, transportation equipment.
Mining: natural gas, petroleum, gypsum.

Gross domestic product
Value of goods and services produced in 2000: $24,061,000,000.
Services include community, business, and personal services; finance; government; trade; and transportation and communication. Industry includes construction, manufacturing, mining, and utilities. Agriculture includes agriculture, fishing, and forestry.

For information on tourism in Nova Scotia, write to: Nova Scotia Tourism and Culture, P.O. Box 456, Halifax, NS B3J 2R3. The Web site at www.novascotia.com also provides tourism information. For information on the economy of Nova Scotia, write to: Economic Development, P.O. Box 319, Halifax, NS B3J 2R7. For information on the government and history of the province, write to: Public Inquiries, P.O. Box 2734, Halifax, NS B3J 3P7. A Web site maintained by the Nova Scotia government at www.gov.ns.ca/about.htm provides a gateway to much useful information about the province's economy, government, and history.

Government

Provincial government
Premier: term of up to 3 years
Members of the Legislative Assembly: 52; terms of up to 3 years

Federal government
Members of the House of Commons: 11
Members of the Senate: 9

Nova Scotia joined with New Brunswick, Ontario, and Quebec in forming the Dominion of Canada.

Halifax, Dartmouth, Bedford, and the rest of Halifax County were combined to form the Halifax Regional Municipality.

- Under the Peace of Paris, France officially gave Cape Breton Island to Britain.

The Canso Causeway was opened, linking the Nova Scotia mainland with Cape Breton Island.
People

Population. The 2001 Canadian census reported that Nova Scotia had 908,007 people. The province’s population had decreased by less than one percent since the 1996 census, which reported a total of 909,282.

Most Nova Scotians belong to families that originally came from Scotland, other parts of the United Kingdom, or Ireland. Significant numbers of others are of French, German, African, and Micmac ancestry. A few people in Cape Breton still speak the Gaelic language of their Scottish ancestors. Each year, St. Ann’s and some other communities hold Scottish celebrations. These gatherings feature Scottish athletic competitions known as Highland Games, colorful costumes, and singing and dancing to bagpipe music. Other festivities are held regularly to celebrate the cultures of Nova Scotia’s French, German, black, and Micmac minorities.

Halifax is the capital of Nova Scotia and by far the largest of the province’s three regional municipalities. It includes the communities of Halifax, Dartmouth, and Bedford and the surrounding area. Halifax is one of the most important ports in Canada, as well as being the chief railway and air terminal in Nova Scotia. The Halifax Regional Municipality includes the population center of the province’s only Census Metropolitan Area as defined by Statistics Canada.

Nova Scotia’s second largest regional municipality is the Cape Breton Regional Municipality. It is located on Cape Breton Island and includes the communities of Sydney and Glace Bay. Nova Scotia’s towns have populations of less than 25,000. See the separate articles on the communities of Nova Scotia listed in the Related articles at the end of this article.

Schools. Public schools in Nova Scotia operate under the provincial Education Act. Nova Scotia’s first Education Act was passed in 1766.

The provincial Department of Education supervises the school system. Schools are controlled by locally elected school boards. Each board may include one appointed member of Micmac descent. School boards do not have taxing powers. Funding from the provincial government and from municipalities provides income for the schools. Provincial law requires children to attend school from age 5 to 16. Alternatives to public education include private schools and home schooling, which are both subject to provincial standards.

Libraries. Nova Scotia has nine regional library systems. Regional libraries are funded primarily by the provincial government and municipal councils. Nova Scotia also has a number of college and university libraries.

Museums. The Citadel in Halifax and Fortress of Louisbourg in Louisbourg feature examples of colonial architecture. Both of these national historic sites also present reenactments of life in garrison towns of the past. Grand Pré National Historic Site near Wolfville commemorates Acadia history. Sherbrooke Village in Sherbrooke is a restored town of the 1800’s. The Maritime Museum of the Atlantic in Halifax has exhibits on the famous steamer Titanic. Other notable attractions include Alexander Graham Bell National Historic Site in Baddeck; Fort Anne and Port Royal national historic sites, both in Annapolis Royal; Nova Scotia Museum of Natural History in Halifax; and the Fisheries Museum of the Atlantic in Lunenburg.

Universities and colleges

Nova Scotia has 10 degree-granting universities and colleges that are members of the Association of Universities and Colleges of Canada.

Population density

Most of Nova Scotia’s people live near the coast. Most of the interior is uninhabited or thinly settled. Halifax is the province’s capital and largest regional municipality.

Dalhousie University, located in Halifax and founded in 1818, is the province’s largest university. The Arts and Administration Building, shown here, stands in the center of the campus.

Visitor's guide

Nova Scotia's beaches and shoreline resorts attract many visitors. Fishing enthusiasts can catch striped bass, cod, haddock, and tuna along the coast, and salmon, shad, and trout in the streams. Visitors can also enjoy such sports as canoeing, sailboating, and sea kayaking. The province also has many parks and campgrounds. Halifax, the capital of Nova Scotia and one of the most historic places in Canada, has a number of historic buildings. See Halifax.

Places to visit

Following are brief descriptions of some of Nova Scotia's many interesting places to visit:

Bluenose II, based in Lunenburg, is a replica of Bluenose, a Canadian schooner that won the International Fisherman's Trophy in 1921, 1922, 1923, 1931, and 1938. Visitors may tour Bluenose II when it is in port and may take cruises in June, July, August, and September.

Cabot Trail offers motorists a magnificent view of the sea. This highway winds through the wilderness areas of northern Cape Breton Island.

Celtic Trail follows the northwest shore of Cape Breton. It offers a view of saltwater cliffs, beaches, and hills and valleys.

Evangeline Trail winds through fishing villages and rolling farmland in the Annapolis Valley of Nova Scotia.

Glooscap Trail offers glimpses of the world-famous fossil cliffs at Joggins and the spectacular tidal bore, caused by the highest tides in the world.

The Lighthouse Route, between Yarmouth and Halifax, passes fishing villages and famous shipbuilding towns.

Marine Drive extends for 250 miles (400 kilometers) along the eastern shore of Nova Scotia's Atlantic coast.

Provincial parks. Nova Scotia has about 120 provincial parks. For information on them, write to Department of Natural Resources, Parks and Recreation Division, RR 1, Belmont, NS B0M 1C0. The department's Web site at www.gov.ns.ca/natr also provides information on Nova Scotia's provincial parks.

Many visitors attend the Gaelic festival in St. Ann's. They enjoy listening to the sound of bagpipe music and watching the Scottish sport of tossing the caber. In this event, contestants throw the caber (a heavy wooden pole) end over end as far as they can. Winter sports in Nova Scotia include curling, hockey, skating, and skiing. Nova Scotians enjoy festivities celebrating the many aspects of their heritage. The Highland Games, a well-known Scottish festival, takes place in Antigonish in July.

Places not shown on map: key shows general location. Source: 2001 census.
Annual events

May-October

Apple Blossom Festival in the Annapolis Valley between Digby and Windsor (May); Nova Scotia International Tattoo in Halifax (July); Lobster Carnival in Pictou (July); Acadian Festival in Church Point (July); Highland Games and Scottish Festival in Halifax (July); Festival of the Tartans in New Glasgow (July); International Busker Festival in Halifax (August); Summer Craft Festival in Halifax (August); Mahone Bay Wooden Boat Festival (August); Nova Scotia Fisheries Exhibition in Lunenburg (September); Hants County Exhibition in Windsor (September); Pumpkin People Celebration in Kentville (October).
Land and climate

Land regions. Nova Scotia has three main land regions. They are (1) the Atlantic Plateau, (2) the Highlands, and (3) the Lowlands.

The Atlantic Plateau rises gradually from sea level on the Atlantic coast to about 700 feet (220 meters) inland. Hard rocks from 400 million to 500 million years old generally lie beneath the surface of the region. These rocks were worn down to sea level to form a plain. About 70 million years ago, the plain uplifted slightly and tilted so that it sloped to the southeast. In the last ice age, which ended about 11,500 years ago, glaciers removed most of the topsoil, exposing bedrock in many places. The action of glaciers also created many lakes and bogs. Today, the Atlantic Plateau is covered with forests, and the land is unsuitable for farming.

The Northern Highlands consist of masses of harder rocks that are generally over 400 million years old. These rocks form the rugged slopes of the Cobequid Mountains, the Pictou-Antigonish Highlands, and the Cape Breton Highlands. The highest point in Nova Scotia rises to 1,747 feet (532 meters) above sea level in Cape Breton Highlands National Park.

The Lowlands lie mainly in central and northern Nova Scotia. Soft rocks about 200 million to 330 million years old lie beneath the surface of the region. They have worn down more rapidly than the harder rocks in the hills and plateaus of Nova Scotia’s other regions.

The Lowlands are gently rolling plains. They have Nova Scotia’s finest soils and mineral deposits. The rich farmland of the Annapolis Valley is south of North Mountain, which rises along the Bay of Fundy. Fertile marshlands lie at the head of the Bay of Fundy, along the inlets called Chignecto Bay and Minas Basin. These marshlands also extend far inland along many rivers. Beneath the Lowlands are rich deposits of coal and gypsum. There are also deposits of limestone, quartz, rock salt, sandstone, and shale.

Coastline of Nova Scotia measures 4,709 miles (7,679 kilometers). This includes 2,517 miles (4,051 kilometers) of mainland, 1,170 miles (1,883 kilometers) of major islands and 1,022 miles (1,645 kilometers) of minor islands. The rocky southern shore has many inlets. Fishing fleets use the large inlets as harbors. Small islands lie off the southern coast.

Rivers and lakes. Nova Scotia’s rivers are all narrow, and few are over 30 miles (80 kilometers) long. The Mersey and the St. Mary’s rivers, both 72 miles (116 kilometers) long, are the longest in the province. The Mersey rises on South Mountain and flows through several lakes, including Lake Rossignol. Rich farmland lies along the Annapolis and Shubenacadie rivers, which flow into the Bay of Fundy. Other important rivers include the La Have and Musquodoboit, which flow into the Atlantic, and the Margaree on Cape Breton Island. Many of Nova Scotia’s rivers rise and fall with the tides near their mouths, and carry salt water inland. Dikes protect some lowlands from rivers that could overflow their banks at high tide.

Nova Scotia has more than 400 lakes. Most of them are small. Bras d’Or Lake, the largest, covers 360 square miles (932 square kilometers) on Cape Breton Island. This saltwater lake nearly divides the island in two. The largest freshwater lakes are, in order of size, Lake Rossignol in Queens County, Lake Ainslie on Cape Breton

The southern coastline of Nova Scotia has many inlets. Numerous small islands lie off the province’s southern shore.
Island, Kejimkujik Lake in Queens and Annapolis counties, and Grand Lake near Halifax.

Plant and animal life. Forests cover about 75 percent of Nova Scotia. Birch, fir, maps, pines, and spruces are the most common trees. Other plants found in the province include the blueberry, bracken, lambkill, mayflower, raspberry, rhodora, sweet fern, and wintergreen.

The white-tailed deer is Nova Scotia's most common large animal. Some black bears, coyotes, moose, and wildcats also live in wilderness areas. Small animals of Nova Scotia include beavers, minks, muskrats, otters, porcupines, red foxes, skunks, and weasels. The province has several kinds of geese and ducks, as well as pheasants, ruffled grouse, and woodcocks. Salmon and trout swim in the streams of Nova Scotia. The coastal waters of the province contain clams, crabs, cod, flounder, haddock, halibut, herring, lobsters, mackerel, pollock, redfish, scallops, and swordfish.

Climate. The sea nearly surrounds Nova Scotia and keeps the climate from becoming extremely hot or cold. The province has an average January temperature of 23 °F (−5 °C). The average July temperature is 64 °F (18 °C). The Atlantic coast is the coolest area of Nova Scotia in summer, but it has the mildest temperatures in winter. The interior and north have hotter summers and colder winters. But even in these areas, winter temperatures seldom fall below 0 °F (−18 °C). In winter, coastal areas of the northern mainland and western Cape Breton Island are chilled by winds crossing the ice-filled Gulf of St. Lawrence.

In spring and early summer, fogs are frequent along the Atlantic and Fundy coasts. Late summer and autumn bring sunny skies and pleasant southwesterly winds to the southern coast of the province.

Nova Scotia's precipitation (rain, melted snow, and other forms of moisture) averages 53 inches (134 centimeters) a year. Rainfall in the province is heaviest along the Atlantic coast. Annual snowfall is highest where onshore winds blow onto highlands and is greater than 100 inches (250 centimeters) in the Cape Breton Highlands. The lowlands and the Atlantic coast usually receive less than 70 inches (180 centimeters) a year.

The Northern Highlands region includes steep bluffs on Cape Breton Island. Cabot Trail, above, winds along the northern part of the island and is a favorite route for visitors.
Economy

The vast majority of Nova Scotia's workers find jobs in service industries, which include activities such as health care, retail trade, education, tourism, and finance. Nova Scotia also has important manufacturing and fishing industries.

Natural resources. Nova Scotia's most valuable resources include its mineral deposits, forests, and fertile lowlands.

Soil. The Annapolis Valley has the best farmland. Other good farming areas include the marshlands at the head of the Bay of Fundy, the central lowlands near Truro, and the coastal lowlands along the Northumberland Strait. The Northern Highlands and Atlantic Plateau regions have shallow, rocky soil.

Minerals in Nova Scotia include two of North America's largest deposits of gypsum, at Windsor and East Hillard. Although the province's last coal mine closed in 2001, significant coal deposits still lie underground from Minas to the Nova Scotia mainland to Glace Bay on Cape Breton Island. Natural gas and oil deposits lie beneath the shallow waters around Sable Island. Other important mineral resources include barite, clay, limestone, peat, salt, and sand and gravel.

Service industries, taken together, produce the largest portion of Nova Scotia's gross domestic product (GDP)—the total value of all goods and services produced in the province in a year. Community, business, and personal services form the province's leading service industry. Businesses in this industry group include educational, health care, and recreational facilities; engineering and legal firms; and hotels and restaurants.

Community, business, and personal services employ more people than any other service industry group in Nova Scotia.

Finance, insurance, and real estate form the province's second-ranking service industry. Halifax is the center of both finance and wholesale and retail trade in the Atlantic Provinces. Other service industries are government, and transportation and communication. The federal and provincial governments are major employers in Nova Scotia. Information about transportation and communication can be found later in this section.

Manufacturing. Nova Scotia's manufactured products have a value added by manufacture of about $2.1 billion Canadian dollars yearly. This figure represents the difference between the value of raw materials and the

value of finished products manufactured from them.

Food and beverage processing is the leading manufacturing activity in Nova Scotia. Fish products provide much of the income. Dozens of fish-processing plants are scattered along the coast. Other important processed foods include dairy products, meat and poultry products, and preserved fruits.

Paper products rank second in importance among Nova Scotia's manufactured products. The province's paper products include newsprint and cardboard containers. Major centers of production include the Huntsport, Liverpool, Pictou, and Port Hawkesbury areas.

Tires and transportation equipment rank next in value among the province's manufactured products. Large Michelin tire plants operate near Bridgewater, Kentville, and New Glasgow. Establishments in Nova Scotia manufacture aircraft parts and boats. The province's other manufactured products include printed materials, wood products, and petroleum products. The Halifax area has an oil refinery.

Fishing. Nova Scotia ranks first among the provinces in the value of fish caught. Lobsters are Nova Scotia's most valuable catch. Other leading catches are scallops, herring, shrimp, and crab. The once-important cod stocks in the waters around Nova Scotia have been greatly depleted. Aquaculture (fish farming) has become increasingly important in sheltered waters along the Atlantic coast and Bras D'Or Lake.

Mining. Nova Scotia's most valuable mineral products are natural gas, petroleum, and gypsum. Natural gas and petroleum are mined near Sable Island, off Nova Scotia's southeastern coast. Gypsum comes from Hants, Inverness, and Victoria counties. Nova Scotia's other mineral products include crushed stone, peat, salt, and sand and gravel.

Agriculture. Nova Scotia has about 4,500 farms. Farmland covers about 8 percent of the province's land area.

Livestock and livestock products provide most of the province's farm income. Milk is the leading farm product. The chief dairying regions are in Colchester County and the Annapolis Valley. Other leading farm products include beef cattle, chickens and eggs, and hogs.

Blueberries and apples are the most valuable crops grown in Nova Scotia. Potatoes, strawberries, and tobacco are also important. Other agricultural activities include the operation of mink farms and Christmas tree nurseries.

Forestry. Nova Scotia's forests supply wood for its pulp and paper mills, lumber mills, boatyards, and furniture factories. Maple and yellow birch are the chief hardwoods of the province. The chief softwoods include balsam fir and spruces.

Electric power. Power plants fueled by coal, oil, and natural gas generate about 90 percent of Nova Scotia's electric power. Hydroelectric plants supply most of the rest. The first tidal power plant in North America operates at the mouth of the Annapolis River.

Transportation. Nova Scotia's major provincial highways run mainly along the coastal areas of the western part of the province. Part of the Trans-Canada Highway stretches from Amherst to North Sydney. Automobiles and trains travel 1,100 miles (1,770 kilometers) from the Nova Scotia mainland to Cape Breton Island over a causeway (elevated road) built across the Strait of Canso.

Halifax has the province's largest airport and seaport. Sydney and Yarmouth also have major airports. Railways link Nova Scotia's largest cities to a national railroad network. Ferries and other passenger ships connect coastal towns with ports in Maine, New Brunswick, Newfoundland, and Prince Edward Island.

Communication. Nova Scotia has about 50 newspapers, including 8 dailies. The Halifax Gazette, founded in 1752, was the first newspaper published in Canada. It is still published as the Royal Gazette by the provincial government. Daily newspapers with the largest circulations are The Chronicle Herald and Mail Star of Halifax, The Daily News of Dartmouth, and The Cape Breton Post of Sydney.

The province has about 20 radio stations and 2 television stations. Cable television systems serve many communities. The first radio station, CHNS, began broadcasting from Halifax in 1926. The first television station, CJCB-TV, began operating in Sydney in 1954.
Lieutenant governor of Nova Scotia represents the British monarch, Queen Elizabeth II, in her role as the queen of Canada. The lieutenant governor is appointed by the governor general in council of Canada. The position of lieutenant governor is largely honorary.

Premier of Nova Scotia is the actual head of the provincial government. Nova Scotia, like Canada itself, has a parliamentary form of government. The premier is an elected member of the Legislative Assembly. The person who serves as premier is usually the leader of the majority party in the Assembly.

The premier presides over the Executive Council (cabinet). The Council is made up of the premier and other ministers. All the ministers belong to the Assembly’s majority party. They are chosen by the premier. Each Council member usually directs one or more governmental departments. The Council resigns if it loses the support of a majority of the Assembly.

Legislative Assembly makes the provincial laws. This one-house legislature has 52 members elected by the people. An election for the Assembly must be held at least every five years. But the lieutenant governor, on the advice of the premier, may call for an election at any time. A premier who loses the support of the majority of the Assembly must resign, and a new election is held.

Courts. Nova Scotia has a superior court system with two divisions, the Supreme Court and the Court of Appeal. The Supreme Court consists of a chief justice, an associate chief justice, and 23 other judges. The Court of Appeal consists of a chief justice and 8 other judges. The chief justice of the Court of Appeal also serves as the chief justice of Nova Scotia.

The governor general in council appoints the province’s Superior Court judges, who may serve until the age of 70. The lieutenant governor appoints provincial judges, justices of the peace, and judges of the probate and family courts, all of whom may serve until age 65.

Local government. Nova Scotia has 18 counties, 3 regional municipalities, and 31 towns. Voters from each regional municipality and town elect a mayor and a council. All other communities are part of 21 districts called rural municipalities. Nine counties are single rural municipalities, six are divided into two rural municipalities apiece, and the other three are regional municipalities. An elected council governs each rural municipality. Members of the council, called councilors, elect a warden (chief councilor) from their group.

Revenue. Nova Scotia gets more than half of its general revenue (income) from taxes levied by the provincial government. Most of this money comes from taxes on income and on goods and services. Sales of gasoline and tobacco products are also taxed. Other sources of revenue include national and provincial tax-sharing programs and license and permit fees.

Politics. Nova Scotia’s leading political organizations are the Liberal Party, the Progressive Conservative Party, and the New Democratic Party. An earlier Conservative Party changed its name to the Progressive Conservative Party in 1942. Since 1867, when Nova Scotia became a province, Liberals have held the office of premier about twice as long as have Conservatives.

The Nova Scotia Legislative Assembly meets in chambers in Province House in Halifax. The Assembly’s 52 members are elected to terms of up to five years.
Indian days. Human beings have lived in Nova Scotia for at least 10,000 years. The earliest people, called Paleo Indians, were hunters who lived mainly off herds of caribou. Their successors, the Micmac, hunted and fished along the coast in the summer and in the forested interior during the winter. See Micmac Indians.

Exploration and settlement. The English explorer John Cabot may have landed in Nova Scotia or in Newfoundland as early as 1497. Cabot believed he had landed in Asia. Between 1520 and 1524, several other explorers reached Nova Scotia while trying to find a westward sea route to Asia. They included the Italian navigator Giovanni da Verrazzano and two Portuguese sailors, João Alvarez Fagundes and Estevan Gomez. Verrazzano explored in the service of France. Gomez sailed in the service of Spain. During the summers of the late 1500's, French fishermen used the Nova Scotia shore for drying codfish they had caught nearby. These fishermen returned to France every autumn.

In 1603, King Henry IV of France gave land including Nova Scotia to a French explorer, Pierre du Gua (or du Guast). Sieur de Monts. De Monts and another French explorer, Samuel de Champlain, sailed along the Nova Scotia coast in 1604. Champlain made the first accurate chart of the coast. The Nova Scotia region and the land around it became known as Acadia (see Acadia). De Monts and Champlain established a colony in the New Brunswick region near the mouth of the St. Croix River. In 1605, this colony was moved to Nova Scotia and became Port Royal. This settlement was initially designed to provide an outpost for the fur trade. It was also supposed to serve as a center for French attempts to convert the Micmac to Christianity. By the mid-1600's, most settlers worked as farmers.

The struggle in Acadia. In 1613, the French colony at Port Royal was captured and burned by English raiders from Virginia. Samuel Argall, a sea captain, led the attack. For over a hundred years the English and the French battled, off and on, for control of Acadia.

In 1621, King James I of England and Scotland made a land grant to Sir William Alexander. The grant included what is now Nova Scotia and also New Brunswick, Prince Edward Island, part of Quebec, and part of Maine. Alexander named the region Nova Scotia, Latin for New Scotland. In 1629, Alexander's son, Sir William the younger, built a new fort at Port Royal. But the colony lasted only until 1632.

France received Port Royal in 1632 under the Treaty of St. Germain-en-Laye. Colonists sent by a French company took control of Port Royal and also settled at La Have. The settlers became known as Acadians. In 1636, the French reestablished Port Royal, at what is now the town of Annapolis Royal, when they built a fort there.

English troops under Sir William Phips captured Port Royal in 1690. But England gave Port Royal back to France under the Treaty of Ryswick in 1697. A combined force of troops from England and New England took Port Royal again in 1710. That year, the British changed the name of the fort from Port Royal to Port Anne. The nearby town became known as Annapolis Royal.

France gave up the mainland of Nova Scotia under the Treaty of Utrecht in 1713. This treaty made British subjects of the French who stayed in Nova Scotia. The treaty also gave Cape Breton Island (then called Ile Royale) and Prince Edward Island (then called Ile Saint-Jean) to France. The French built a fortress at Louisbourg on Cape Breton Island to assert their power in the region. British troops from New England captured the fortress in 1745 with the aid of the Royal Navy. France regained it in 1748 under the Treaty of Aix-la-Chapelle, which settled a European war. But Louisbourg fell to the British during the Seven Years' War (1756-1763).

British settlers established Halifax in 1749. It became Nova Scotia's capital the same year. Many French, German, and Swiss Protestants came to Nova Scotia in the early 1750's to escape religious persecution in Europe. In 1735, British colonial troops from New England began to drive out of Nova Scotia the Acadians who refused to swear complete allegiance to Britain. Many Acadians died in this upheaval, and thousands fled to Prince Edward Island, Quebec, the French colony of Louisiana, France, and British colonies in America. But by the 1760's, Acadian survivors began to return to Nova Scotia.

Progress as a province. In 1738, the British government allowed colonists in Nova Scotia to elect a representative assembly. The first assembly met in Halifax.

The First Battle of Louisbourg was a key British victory during the French and Indian wars. British troops from New England helped capture the French fortress of Louisbourg in 1745.
Nova Scotia

Giovanni da Verrazzano, an Italian navigator, sailed along the coast of Nova Scotia in the service of France in 1524. He was one of the first people to explore the coast.

Halifax was founded in 1749 by the English governor Edward Cornwallis. He made Halifax the capital of Nova Scotia.

Port Royal, one of the oldest towns in North America, was founded in 1605. The British changed the name to Annapolis Royal in 1710.

British colonial troops from New England began in 1755 to drive French Acadians away from Nova Scotia.

The first British victory in Nova Scotia occurred when seamen captured and burned Port Royal in 1613.

Important dates in Nova Scotia

- 1497-1524 European explorers reached Nova Scotia while seeking a sea route to Asia.
- 1603 King Henry IV of France commissioned Pierre du Gua, Sieur de Monts, to colonize Acadia.
- 1604 Samuel de Champlain charted the Nova Scotia coast.
- 1605 Champlain and De Monts founded Port Royal.
- 1710 The British captured Port Royal and changed its name to Annapolis Royal.
- 1713 Under the Treaty of Utrecht, France gave Britain the mainland of Nova Scotia.
- 1749 The British founded Halifax.
- 1755 British colonial troops from New England began to drive out of Nova Scotia Acadians who would not swear allegiance to Britain.
- 1758 The first provincial parliament of Nova Scotia met in Halifax.
- 1776-1785 United Empire Loyalists came to Nova Scotia from the United States.
- 1848 Nova Scotia became the first part of Canada to get Responsible Government (local self-government).
- 1867 Nova Scotia joined with New Brunswick, Ontario, and Quebec in forming the Dominion of Canada.
- 1917 A French munitions ship exploded in Halifax Harbour and killed about 2,000 people.
- 1939-1945 Halifax became a base for convoys sailing to and from Europe during World War II.
- 1967 Parliament established the Cape Breton Development Corporation to attract new industry to the area.
gave the people some voice in their government. But a governor and a council appointed by the king really ruled the province. In 1763, the Peace of Paris officially gave Cape Breton Island to Britain.

In 1760, more than 20 ships carrying New Englanders arrived in Nova Scotia. The New Englanders took over the land the Acadians had cleared, and they established many new settlements. During and after the Revolutionary War in America (1775-1783), about 35,000 people came to Nova Scotia from the United States. Most of the people, called Loyalists or United Empire Loyalists, were British colonists in America who refused to fight against Britain in the Revolutionary War. They established Shelburne and also settled in Guysborough, Digby, and other towns. Some Loyalists were blacks who had been promised freedom from slavery in Nova Scotia.

Protestant and Roman Catholic settlers from Scotland began arriving in Nova Scotia in 1773. They continued to immigrate in large numbers for over 50 years, becoming a major group in eastern Nova Scotia. Irish Catholic immigrants also arrived in the early 1800's, settling chiefly in and around Halifax. More blacks came from the United States during the War of 1812 (1812-1815).

Nova Scotians gained control over local affairs in 1848 when the British government granted Nova Scotia a governing council controlled by the elected assembly. Nova Scotia became the first completely self-governing colony within the British Empire. Joseph Howe, a forceful editor and statesman of Nova Scotia, had led the fight to win the new government for the colony.

During the 1800's, Nova Scotia thrived with growing industries and increasing world trade. Shipbuilders used timber from the province's forests to build merchant ships. By 1860, Nova Scotia had one of the largest merchant fleets in the world.

In 1867, Nova Scotia joined with New Brunswick, Ontario, and Quebec in forming a confederation called the Dominion of Canada (see British North America Act). The next 25 years brought economic hardship to Nova Scotia. During this time, investors abandoned shipping in an effort to industrialize Nova Scotia. However, this effort failed. But during the late 1890's, Nova Scotia's steel industry and coal production began to thrive.

The early to middle 1900's. During World War I (1914-1918), Halifax served as the headquarters of Allied convoys sailing between North America and Europe. In 1917, a French military supply ship exploded in Halifax Harbour. The blast killed about 2,000 people and damaged much of the city.

During the next 20 years, the province experienced an economic crisis and political unrest. Many people left Nova Scotia. After a brief period of bustle during World War II (1939-1945), hard times returned to the province.

In the mid-1950's, Canada's overall postwar prosperity began to trickle down to Nova Scotia. The economy of the province grew. Schools, hospitals, and a modern network of roads were constructed. The Nova Scotia section of the Trans-Canada Highway was built across the province. In 1955, the Canso Causeway, linking the mainland and Cape Breton Island, was completed. It contributed to the province's economic growth and to expansion of the tourist industry. In this period, the rural population of Nova Scotia declined. But people migrated to urban areas within the province rather than to other parts of Canada or to New England.

Beginning in the 1950's, Canada's federal government and Nova Scotia's provincial government worked to promote economic growth within Nova Scotia. A series of provincial and federal agencies were created that sought to close outdated industries and attract new ones. These agencies included Industrial Estates Limited (established in 1957), the Cape Breton Development Corporation (1967), Sydney Steel Corporation (1969), and Nova Scotia Power Corporation (1973).

The expansion of industry and port facilities helped improve Nova Scotia's economy in the 1970's. For example, a container terminal opened in 1970 at the Port of Halifax to handle large container ships. During the early 1970's, an industrial park was built on the shores of the Strait of Canso.

Recent developments. Several important economic developments took place in Nova Scotia during the 1980's and early 1990's. Facilities were expanded at the Port of Halifax. Oil production began around Sable Island. On the other hand, the decline of several industries hurt the provincial economy. For example, the once-important cod fishery of the province virtually collapsed due to overfishing, and coal mining in Pictou County closed down.

Today, Nova Scotia faces a number of economic problems. A slowdown in Canada's overall economy and efforts to balance the federal budget have reduced the amount of federal funds available for Nova Scotia. As a result, government enterprises have been cut back. Both Nova Scotia Power and Sydney Steel have been sold to private investors. Municipal governments, hospitals and school boards, and institutions of higher education are being combined to save money. Gambling casinos have been legalized to provide the province with a source of income.

Novâlris, noh VAH lihs (1772-1801), was the pen name of Baron Friedrich von Hardenberg, a German romantic poet. Five poems by Novâlris, called Hymns to the Night (1800), express his religious, mystical nature, and a longing for death. In the essay Christianity or Europe (1799), Novâlris tried to show that people lived more meaningful lives in the spiritual unity of the Catholic Middle Ages than in his own time. This attitude became a theme of German romanticism.

Novâlris was born in Saxony. The death of his 15-year-old fiancée in 1797 deepened his melancholy and his religious temperament. Novâlris’s work as a mining engineer brought him close to the land and intensified his love of nature and its mysteries. Jeffrey L. Sammons

Novaya Zemlya, NOH vuh yuh ZEHM lee AH, is a group of islands in the Arctic Ocean that separate the Barents Sea from the Kara Sea. The islands are part of Russia. The Russian name means new land and commonly refers to the two largest islands. The northern large island covers about 20,000 square miles (52,000 square kilometers). Glaciers blanket much of it. The southern large island has an area of about 15,000 square miles (38,800 square kilometers), most of which is a treeless plain. Both islands have large deposits of coal and one copper, lead, and zinc.

Early Russians first discovered Novaya Zemlya between the 1000’s and 1100’s. But the islands remained uninhabited until 1877, when an Arctic people called Samoyeds established the first permanent settlements. A small colony of Russians and Samoyeds live on the southern island. Islanders raise reindeer, trap and hunt animals, and collect eider down the feathers of eider ducks. The Soviet Union tested nuclear bombs on the northern island in the 1950’s. Today, the island shows harmful levels of radiation. Craig ZumBrunnen

Novel is a long fictional story written in prose. It is one of the most popular forms of literature. The subject matter of novels covers the whole range of human experience and imagination. Some novels portray true-to-life characters and events. Writers of such realistic novels try to represent life as it is. In contrast to realistic novels, romantic novels portray idealized versions of life. Some novels explore purely imaginary worlds. For example, science-fiction novels may describe events that take place in the future or on other planets. Other popular kinds of novels include detective novels and mysteries, whose suspenseful plots fascinate readers.

Some novels point out evils that exist in society and challenge the reader to seek social or political reforms. Novels may also provide knowledge about unfamiliar subjects or give new insights into familiar ones.

The novel has four basic features that together distinguish it from other kinds of literature. First, a novel is a narrative—that is, a story presented by a teller. It thus differs from a drama, which presents a story through the speech and actions of characters on a stage.

Second, novels are longer than short stories, fairy tales, and most other types of narratives. Novels vary greatly in length, but most exceed 60,000 words. Because of their length, novels can cover a longer period and include more characters than can most other kinds of narratives.

Third, a novel is written in prose rather than verse. This feature distinguishes novels from narrative poems.

Fourth, novels are works of fiction. They differ from histories, biographies, and other long prose narratives that tell about real events and people. Novelists sometimes base their stories on actual events or the lives of real people. But these authors also make up incidents and characters. Therefore, all novels are partly, if not entirely, imaginary.

The basic features of the novel make it a uniquely flexible form of literature. Novelists can arrange incidents, describe places, and represent characters in an almost limitless variety of ways. They also may narrate their stories from different points of view. In some novels, for example, one of the characters may tell the story. In others, the events may be described from the viewpoint of a person outside of the story. Some novelists change the point of view from one section of a story to another. Novelists also vary their treatment of time. They may devote hundreds of pages to the description of the events of a single day, or they may cover many years within a few paragraphs.

Origins of the novel

This article discusses the development of the novel in Western literature. The history of the novel is marked by
an almost continual development of variations on old narrative forms. No matter how up to date or localized novels may seem, their stories still employ many themes and issues from narrative forms dating back to the ancient Greeks and Romans.

**Ancient Greek and Roman narratives.** In ancient times, most long narratives were composed in verse. Histories were among the few kinds of long narratives written in prose. The earliest known histories were written by two Greek authors, Herodotus and Thucydides, during the 400's B.C.

The finest fictional narratives of ancient Greece were long poems called *epics,* which told about the deeds of legendary heroes and mythical gods. The *Iliad* and the *Odyssey,* the two most famous epics, were probably composed by Homer between 800 and 700 B.C.

The Greeks also wrote long fictional adventure stories. These tales described fantastic adventures in foreign countries or related the plights of young lovers. Some writers composed *pastoral* tales, which told of love between shepherds and maidsens. One of the best-known Greek pastoral is *Daphnis and Chloe* (A.D. 100s or 200s) by Longus.

The most important Roman narratives in prose included *Satyricon* (about 60 A.D.) by Petronius and *Metamorphoses,* or *The Golden Ass* (mid-100s A.D.), by Lucius Apuleius. These earthy stories contrast sharply with the love stories of the Greeks. *Satyricon* vividly portrays the adventures of three Roman scamps. *Metamorphoses* tells of a man who is changed into a donkey and travels through various countries observing the weaknesses and failings of humans.

**Medieval narratives.** The word *novel* originally referred to prose stories that were topical. The word for *novel* in French and other languages deriving from classical Latin is *roman.* The word reflects the fictions called *romances* in which it had its roots. Love and adventure stories called *romances of chivalry* became widely popular during the late Middle Ages. Many of the romances dealt with the legendary British King Arthur and his Knights of the Round Table.

**Early novels.** During the 1500s and 1600s, many English romances were written in an extremely decorative style. After John Lyly of England wrote *Euphues: The Anatomy of Wit* (1578), this highly artificial style was called *euphuistic* and was widely imitated. In France, many romances and romance histories were written by important women writers. Madeleine de Scudéry wrote historical narratives, such as *Artamene,* or *The Great Cyrus* (1649-1653). Marie-Madeleine de La Fayette wrote the most psychologically powerful of these novels, *The Princess of Cleves* (1678).

In Spain, several narratives that were more realistic appeared during the 1500s. One of the most influential was *Lazarillo de Tormes* (1554), by an unknown Spanish author. Some critics consider it the first *picaresque novel.* These novels describe the adventures of a young *picaro* (rogue) who makes his way in the world through cunning and treachery. *Picaresque novels* are episodic like romances about knights, but in *Lazarillo de Tormes,* the rogue replaces the knight as the hero.

The first classic novel, according to some critics, was the Spanish masterpiece *Don Quixote* (part I 1605, part II 1615) by Miguel de Cervantes. Cervante's story combines the chivalric romance and the picaresque adventure. The central character in *Don Quixote* is a middle-aged country landowner who imagines himself a knight, battling injustice. He differs significantly from the unbelievably heroic or clever characters in romances and picaresque narratives. Cervante's characters resemble real people and often make foolish and costly mistakes.

**The rise of the English novel**

The novel form tends to emphasize realistic social themes. Sophisticated novels of this kind first appeared in England in the early 1700s. At that time, the urge to record the details of ordinary life began to replace the older narrative focus on wondrous, supernatural, remote, and heroic material.

**The first English novelists.** Some critics regard Daniel Defoe as the first novelist, though others credit Aphra Behn with combining the novel form and the romance in her fascinating slave narrative, *Oroonoko* (1688). Defoe's *Robinson Crusoe* (1719) and *Moll Flanders* (1722) consist of a series of episodes in the lives of clever and resourceful, but ordinary, characters.

Samuel Richardson wrote novels with well-developed plots rather than a sequence of episodes. His *Pamela or Virtue Rewarded* (1740) tells of a virtuous female servant who resists her master's attempts to seduce her. The story is told in the form of letters, most of which are written by Pamela, the heroine, to her family. Through the letters, Richardson reveals key psychological aspects of the central character.

Henry Fielding wrote *The History of Tom Jones, a Foundling* (1749), which is especially noted for its elaborately unified plot. This novel tells of the comical adventures of a young orphan, first as he grows up in rural England, and then as he travels toward London, meeting a variety of characters in English life.

Tobias Smollett wrote amusing, loosely constructed novels about eccentric characters. *The Expedition of Humphry Clinker* (1771) is a novel in letter form about a variety of English travelers and personal types.

Laurence Sterne was one of the greatest experimenters in the history of the novel. *The Life and Opinions of Tristram Shandy, Gentleman* (1760-1767). *Tristram Shandy* is an unconventional novel about an unconventional family. The story humorously portrays character types, philosophical ideas, and social customs.

**Gothic novels** became widely popular in England during the late 1700s through the 1800s. These horror stories tell of mysterious events that take place in gloomy, isolated castles. They have suspenseful, action-packed plots. Mary Shelley's *Frankenstein* (1818), about a scientist who creates a monster from parts of dead bodies, and Bram Stoker's *Dracula* (1897), about a nobleman who is secretly a vampire, became the most enduring examples of the type.

**The 1800s**

During the 1800s, English writers elaborated on the techniques of the early novelists and produced many great works. Authors in France, the United States, and Russia also wrote novels of major literary importance. The *romantic movement,* which stressed the need for full expression of human emotions and imagination, dominated the literature of the early 1800s. It was fol-
followed by the realistic movement, which demanded that literature accurately represent life as it is.

**Britain.** Sir Walter Scott, a Scottish writer, created and popularized *historical novels*. Such novels re-create the atmosphere of a past period and include actual characters and events from history. Scott wrote a long series of historical novels, including *Waverley* (1814), about a Scottish rebellion against England.

The novel of manners appeared in England during the late 1700's. Fanny Burney was one of the first writers in the tradition with * Evelina* (1778), a novel about a young woman's introduction to London life. Jane Austen perfected the novel of manners in the early 1800's. Her masterpieces, *Pride and Prejudice* (1813), centers on the social conventions surrounding courtship and marriage.

The English novel flourished during the 1800's, expanding to explore society's classes and institutions. Emily Bronte's *Wuthering Heights* (1847) added both Gothic and romance elements to the novel of manners. Charlotte Bronte's *Jane Eyre* (1847) merged Gothic romance and fictional biography. William Makepeace Thackeray wrote satirically on the hypocrisies of life in London and Paris in *Vanity Fair* (1847-1848). Charles Dickens wrote many great novels about English urban life. *Oliver Twist* (1837-1839) deals with the London underworld.

Anthony Trollope wrote long, detailed novels centering on politics, society, and religion as in the witty *Barchester Towers* (1857). George Eliot portrayed English rural and small-town life. Her greatest work, *MIDDLEMARCH* (1871-1872), deals with the profound moral crises in the lives of landowners and rural professionals. Robert Louis Stevenson wrote *Treasure Island* (1883) and other popular adventure novels. In the late 1800's, Thomas Hardy wrote novels such as *Jude the Obscure* (1895), in which tortured characters were fated to lead desperate lives.

**France.** French writers greatly influenced the development of the novel in the 1800's. Honoré de Balzac wrote a series of novels in the 1830's and 1840's under the collective title *The Human Comedy*. These were the first novels to fully explore the manners and morals of an entire society. Stendhal contributed to the development of the psychological novel in *The Red and the Black* (1830) and to the political novel in *The Charterhouse of Parma* (1839). Alexandre Dumas père and Victor Hugo wrote massive historical novels. The most famous include Dumas's *The Count of Monte Cristo* (1844-1845) and Hugo's *Les Misérables* (1862).

Gustave Flaubert wrote *Madame Bovary* (1856), which tells about a woman unhappy in her marriage to a village doctor. Flaubert's precise objective style influenced many other writers. Émile Zola helped establish *naturalism* as an important literary movement in the late 1800's. According to the theory of naturalism, a person's life is determined by heredity and environment. Naturalistic novels portray people who are trapped by circumstances beyond their control. Many of these novels deal with grim subjects. Zola's *Germinal* (1885), for example, describes the suffering of French miners.

**The United States.** The early American novel was less concerned with social and historical tradition than the European novel. From its beginnings, the American novel explored intense family themes, as in Charles Brockden Brown's *Wieland* (1798), about a man who goes insane and murders his wife and children. American novels also dealt with the frontier landscape, as in James Fenimore Cooper's *The Last of the Mohicans* (1826). Cooper's novel includes one of America's great folk heroes, the frontiersman Natty Bumppo.

The mid-1800's produced classic American novels of moral dilemmas and obsession. Nathaniel Hawthorne's tale of sin, *The Scarlet Letter* (1850), and Herman Melville's symbolic whaling story, *Moby-Dick* (1851), are examples. Harriet Beecher Stowe's *Uncle Tom's Cabin* (1851-1852) was one of the first novels to raise the nation's consciousness about slavery.

In the late 1800's, Mark Twain captured American humor and colloquial speech in *The Adventures of Tom Sawyer* (1876) and *Adventures of Huckleberry Finn* (1884). The later book in particular has been praised for its attack on the social evils of the day and its vivid and realistic portrait of life on the Mississippi River.

William Dean Howells, in his novel *The Rise of Silas Lapham* (1885), became the first American writer to draw on the tradition of social realism coming out of European fiction in the 1800's. Henry James has been acclaimed for his psychological portrayals of sensitive, intelligent characters. James spent much time in England and followed the English tradition of writing about social manners in *The Portrait of a Lady* (1880-1881) and other novels.

**Russia** produced its two greatest novelists, Leo Tolstoy and Fyodor Dostoevsky, during the 1800's. Tolstoy and Dostoevsky rank as masters of the realistic novel. Tolstoy's famous masterpiece, *War and Peace* (1869), centers on the 1812 invasion of Russia by the French emperor Napoleon I. The account of the war is interwoven with stories about the lives of several Russian families. Dostoevsky won fame for his probing psychological insight and his treatment of philosophical ideas. In his novel *Crime and Punishment* (1866), he explored the anguish of a mind of a student who commits two murders.

**The modern novel**

During the 1900's, Novelist experimented with various styles, techniques, and types of plots. World War I (1914-1918) had a major impact on many writers. The noble ideals and high hopes with which nations entered the war were shattered by the length and destruction of the conflict. After the war, many novelists dealt with the social changes and personal disillusionments of modern times. After World War II (1939-1945), novelists continued to explore the problems of modern life, especially the threat of nuclear war.

**New directions in the novel.** Older forms of the novel persisted in the early 1900's, notably in the works of Arnold Bennett and Rudyard Kipling in England. How-
ever, more experimental novelists began to gain prominence. In such novels as *Nostromo* (1904), the Polish-born English novelist Joseph Conrad changed the form of the adventure story. Conrad's stylistic experiments and probing psychological analysis helped shape the future of the novel in the 1900's.

In England, D. H. Lawrence broke many social taboos in writing about sexual passion in such novels as *Woman in Love* (1920). Ford Madox Ford experimented with narration in *The Good Soldier* (1915), in which the narrator discovers that his wife and his best friend have been lovers for years. E. M. Forster raised issues of class and race in *A Passage to India* (1924).

Marcel Proust of France wrote the masterpiece *Remembrance of Things Past* (1913-1927). This seven-part novel deals with many subjects and portrays French society in the process of change during the early 1900's. The hero of French author Louis-Ferdinand Céline's *Journey to the End of the Night* (1932) wanders aimlessly through war-torn Europe.

The Irish writer James Joyce became one of the greatest novelists of the 1900's. In *Portrait of the Artist as a Young Man* (1916), a largely autobiographical novel about his youth, Joyce began to use techniques of narration in which the author presents the thoughts, sensations, and memories that flow through a character's mind. He perfected this technique, called *inner narration* or *stream of consciousness*, in *Ulysses* (1922). This challenging novel compares one day in the life of a 1904 Dublin resident with events in Homer's *Odyssey*.

The English author Virginia Woolf also experimented with interior narration. Her best novels, such as *To the Lighthouse* (1927), are known for their brilliant structure and the emotional power of their style.

The greatest American novelists of the early 1900's included Edith Wharton, Sinclair Lewis, F. Scott Fitzgerald, Ernest Hemingway, William Faulkner, and John Steinbeck. Wharton followed Henry James in such novels of manners as *The Age of Innocence* (1920), about aristocratic New Yorkers of the 1870's. Lewis wrote about middle-class Americans in *Babbitt* (1922). In *The Great Gatsby* (1925), Fitzgerald pictured the false glamour and moral emptiness of wealth, pleasure-seeking Americans of the 1920's, an era called the *Jazz Age*. Hemingway captured the personal letdown and sense of loss that many people felt after World War I in *The Sun Also Rises* (1926). In *The Sound and the Fury* (1929) and other novels, Faulkner dealt with the decline of Southern aristocratic families and the breakdown of traditional standards of behavior. Steinbeck wrote about the Great Depression in such powerful novels as *The Grapes of Wrath* (1939).

The American detective novel made a significant contribution to the modern novel with its realistic language and cynicism. The most important of these novels included *The Maltese Falcon* (1930) by Dashiell Hammett and *The Big Sleep* (1939) by Raymond Chandler.

Franz Kafka, a Czech author who wrote in German, produced puzzling novels that have an atmosphere of fantasy and nightmare. In *The Trial* (1925), Kafka portrayed the frustration and despair of an ordinary man entangled in the workings of a bureaucratic legal system. The German novelist Thomas Mann also wrote about the frustrations of modern life, but the main characters in his novels are sensitive and intellectually gifted. Mann's major novels include *The Magic Mountain* (1924).

Existentialism, a philosophic movement, greatly influenced French literature during the late 1930's and the 1940's. Existentialists emphasized that individuals must choose their own way to live and act in an essentially meaningless world and then accept full responsibility for their actions. The rise of existentialism in France resulted in a number of existential novels, including *Nausea* (1938) by Jean-Paul Sartre and *The Stranger* (1942) by Albert Camus. Sartre and Camus focused on moral issues rather than on experimental techniques.

After World War II. During the 1950's, an experimental form called the *nouveau roman* (new novel) appeared in France. The nouveau roman writers rejected traditional features of novels, such as organized plots and clear-cut types of characters. Instead, they wrote novels that focused on exact descriptions of objects and events. The nouveau roman writers included Alain Robbe-Grillet, Marguerite Duras, and Michel Butor. *Jealousy* (1957) by Robbe-Grillet typifies the nouveau roman. Perhaps the most original novelist of the 1940's and 1950's was Samuel Beckett, an Irish-born author who wrote in both French and English. Beckett was influenced by James Joyce and used the interior narration technique in *Malone Dies* (1951). This novel centers on the repressed hysteria of a dying tramp named Malone.

In England, the leading postwar novelists included Evelyn Waugh, George Orwell, and Graham Greene. Waugh wrote light satirical novels before the war, but his tone later deepened in *Brideshead Revisited* (1945), a study of an aristocratic Roman Catholic family. Orwell's *1984* (1949) deals with life in a totalitarian state. Greene wrote about religious and moral problems in *The Heart of the Matter* (1948). Other postwar English novelists included Kingsley Amis, Anthony Burgess, Doris Lessing, Iris Murdoch, C. P. Snow, and Muriel Spark.

American writers produced fairly conventional novels during the 1950's. One of the most popular novels of this period was *The Catcher in the Rye* (1951) by J. D. Salinger. It tells about the problems of a prep school dropout in New York City. The novels of Saul Bellow, Philip Roth, and Bernard Malamud deal partly with Jewish life in the United States. Bellow followed the form of the pic- aresque narrative in *The Adventures of Augie March* (1953), about a Chicago youth who grows up during the Great Depression. In *The Assistant* (1957), Malamud portrayed the relationship between a poor Jewish shopkeeper and his helper. In *Goodbye, Columbus* (1959), Roth wrote of the strained love affair between a young middle-class Jewish man and a wealthy Jewish girl.

The middle and late 1900's. The black humor style in fiction became popular during the 1960's. Black humorists treat serious subjects in a darkly comic manner. Their novels are both funny and tragic. For example, Catch-22 (1961), by the American author Joseph Heller, deals humorously with the absurdities of warfare and military organizations, but also captures the terrifying confusion of war.

John Updike's Rabbit, Run (1960) is an ironic novel about suburban life in the eastern United States. Philip Roth's Portnoy's Complaint (1969) deals with the sexual neuroses of a young man from a Jewish family.

The novel today features international trends that appeared during the 1960's and 1970's. One of the trends was introduced by a group of authors who wrote nonfiction novels. These novelists combined a documentary style with fictional techniques to tell about actual events and people.

The American writer Truman Capote originated the term "nonfiction novel" to describe his In Cold Blood (1966). Capote based this work on an actual 1959 murder case in which two men killed a Kansas farm family. Many other American authors, including William Styron and Norman Mailer, followed Capote in writing nonfiction novels. In The Confessions of Nat Turner (1967), Styron told the story of an 1831 slave rebellion in Virginia led by Nat Turner, a black preacher. Mailer wrote The Armies of the Night (1968), which describes his experiences in a 1967 protest march in Washington, D.C.

One group of writers created highly imaginative and inventive novels. In some cases, they modernized myths, fairy tales, and other old stories, or they created fantasy worlds. Latin American fiction gained recognition with a kind of novel called magic realism, which blends dreams and magic with everyday reality. The originator of this style was the Argentine writer Jorge Luis Borges. The Colombian writer Gabriel García Márquez wrote a classic of magic realism, One Hundred Years of Solitude (1967), about generations of a strange Latin American family. Manuel Puig of Argentina wrote Kiss of the Spider Woman (1976), about the relationship between two men who share a prison cell. Several other Latin American novelists contributed to the tradition of magic realism, often writing in newer, more experimental forms. These authors included Carlos Fuentes of Mexico in The Death of Artemio Cruz (1962), Mario Vargas Llosa of Peru in The Story of the Hero (1962), and Luisa Valenzuela of Argentina in The Lizard's Tail (1983).

Postwar German novelists produced their own style of magic realism in the fiction of Günter Grass. In Grass's The Tin Drum (1959), the main character can stop time and drown out history. Grass wrote about postwar stress in Germany and Poland in The Call of the Toad (1992). Heinrich Böll dealt with postwar German memories in Group Portrait with Lady (1971).

The Italian writers Italo Calvino and Umberto Eco took the novel back to its roots in allegory, fable, and fairy tale. Calvino wrote The Castle of Crossed Destinies (1973), and Eco wrote The Name of the Rose (1980).

Another international trend in the novel was fiction that reflected the breakup of colonial empires in Africa, Asia, and the Caribbean. Some authors wrote about changes in Australia and Canada. Works reflecting these trends included the South African novels In the Heart of the Country (1977) by J. M. Coetzee and Burger's Daughter (1979) by Nadine Gordimer. Chinua Achebe used Nigerian themes in Things Fall Apart (1958). V. S. Naipaul wrote several highly praised novels set in the West Indies, notably Guerrillas (1975). Salman Rushdie wrote about Indian and Muslim traditions in The Satanic Verses (1988). Patrick White wrote sweeping novels about his homeland of Australia, such as The Tree of Man (1953). Robertson Davies wrote sophisticated novels about Canada, including What's Bred in the Bone (1985).

The novel today continues to explore national themes. Examples include American Pastoral by Philip Roth, Mason & Dixon by Thomas Pynchon, and Underworld by Don DeLillo (all of the United States, all published in 1997), and The God of Small Things (1997) by Arundhati Roy of India.

Doody, Margaret A. The True Story of the Novel. Rutgers, 1996.

November is the 11th month of the year according to the Gregorian calendar, which is used in almost all the world today. It takes its name from novem, the Latin word for nine. In the early Roman calendar, November was the ninth month. Because July was named for Julius Caesar and August for Augustus Caesar, the Roman Senate offered to name the 11th month for Tiberius Caesar. He refused modestly, saying, "What will you do if you have 13 emperors?" Originally there were 30 days in November, then 29, then 31. From the time of Augustus, the month has had 30 days.

November is a month of remembrance. On Dia de los muertos, November 2, Mexicans honor the dead. This holiday is somber, yet has many playful characteristics as well. On November 11, Americans honor war veterans with a national holiday called Veterans Day. In Canada, the holiday is called Remembrance Day. This holiday, also known as Armistice Day in some countries, commemorates the signing of the armistice (temporary peace agreement) that ended World War I (1914-1918).

On the second Sunday of the month, Father's Day is celebrated in Sweden. Children's Book Week is observed in November in many places. November 14 is Children's Day in India. The Japanese festival Shichi-Go-San (Three-Five-Seven) is a special day set aside for children who are 3, 5, or 7 years old. It is held on November 15. Election Day in the United States falls on the first Tuesday after the first Monday of the month.

People in the United States celebrate Thanksgiving Day on the fourth Thursday of November. On Guy Fawkes Day, November 5, people in the United Kingdom recall the Gunpowder Plot of 1605, an unsuccessful

Important November events

1 All Saints’ Day observed by Christians.
- Benvenuto Cellini, Italian goldsmith, born 1500.
- Crawford W. Long, American physician who first used ether as an anesthetic in surgery, born 1815.
2 All Souls' Day observed by Christians.
- Daniel Boone, American frontiersman, born 1734.
- Marie Antoinette, French queen, born 1755.
- Spanish expedition led by Gaspar de Portolá reached San Francisco Bay, 1769.
- James K. Polk, 11th U.S. president, born 1795.
- North Dakota became the 49th U.S. state, 1889.
- South Dakota became the 40th U.S. state, 1889.
3 Stephen Austin, colonizer of Texas, born 1793.
- Vilhjalmur Stefansson, Canadian explorer, born 1879.
- Panama declared its independence from Colombia, 1903.
4 Erie Canal formally opened at New York, 1825.
- Will Rogers, American humorist, born 1879.
5 Guy Fawkes Day in the United Kingdom marks failed Gunpowder Plot to blow up Houses of Parliament, 1605.
- Eugene V. Debs, American labor leader, born 1853.
- Will Durant, American historian, born 1885.
6 John Philip Sousa, American bandmaster, born 1854.
- Ignace Jan Paderewski, Polish pianist, composer, and statesman, born 1860.
- First U.S. intercollegiate football game, Rutgers versus College of New Jersey (Princeton), at Rutgers, 1869.
7 General William Henry Harrison defeated Indians in Battle of Tippecanoe, 1811.
- Marie Curie, French physicist, born 1867.
- Albert Camus, French author, born 1913.
- Bolsheviks ousted provisional Russian government, 1917.
8 Edmund Halley, British astronomer, born 1656.
- Mount Holyoke Female Seminary (today Mount Holyoke College) opened, 1837.
- Montana became the 41st U.S. state, 1889.
9 Ivan Turgenev, Russian novelist, born 1818.
- Edward VII of the United Kingdom born 1841.
- Kaiser Wilhelm II abdicated German throne, 1918.
- Kristallnacht, when Jewish businesses and synagogues throughout Germany were attacked by the Nazis, 1938.
- Cambodia became independent in 1953.
- Opening of the Berlin Wall, Germany, 1989.
10 Martin Luther, German religious leader, born 1483.
- William Hogarth, English painter, born 1697.
- Friedrich Schiller, German playwright and poet, born 1759.
- Sir John S. D. Thompson, Canadian prime minister, born 1844.
- Donald MacMillan, American Arctic explorer, born 1874.
- Remembrance Day, Canada.
- Fyodor Dostoevsky, Russian novelist, born 1821.
- Ned Kelly, Australian bushranger, hanged 1880.
- Washington became the 42nd U.S. state, 1889.
- Poland was proclaimed an independent republic in 1918.
- Armistice signed ending World War I, 1918.
- Veterans Day first celebrated in United States, 1954.
- Joseph Hopkinson, American jurist, born 1770.
- Elizabeth Cady Stanton, American reformer, born 1815.
- Bahá’u'lláh, Bahá’í prophet, born 1817.
- Auguste Rodin, French sculptor, born 1840.
- James Clerk Maxwell, Scottish physicist, born 1831.
- Robert Louis Stevenson, Scottish novelist, born 1850.
- Louis D. Brandeis, American jurist, born 1856.
- Holland Tunnel opened in New York City, 1927.
- Robert Fulton, American inventor, born 1765.
- Claude Monet, French painter, born 1840.
ful attempt to blow up the Houses of Parliament. The day is marked with fireworks and bonfires. In Thailand, Loy Krathong, a water festival, is held in mid-November.

Religious holidays in November include the Christian All Saints' Day on November 1. The Bahá’í observance of the birth of Bahá’u’lláh, who founded the faith, occurs on the 12th. Sikhs commemorate the birth of Nanak, the first Sikh guru (spiritual teacher), in November.

November's flower is the chrysanthemum. The topaz is November's birthstone. — Carole S. Angell

Quotations

November woods are bare and still;
November days are clear and bright;
Each noon burns up the morning's chill,
The morning's snow is gone by night.

— Helen Hunt Jackson

November's sky is chill and drear,
November's leaf is red and rear.

— Sir Walter Scott

Autumn wins you best by this, its mute
Appeal to sympathy for its decay.

— Robert Browning

The wild November comes at last
Beneath a veil of rain;
The night wind blows its folds aside,
Her face is full of pain.

— Richard Henry Stoddard

Novi Sad, NAW vee SAHD(pop. 179,626), is a Yugoslav center of manufacturing and transportation. The city lies in Serbia, about 45 miles (72 kilometers) northwest of Belgrade. For location, see Serbia (map). The Danube River meets the Mali Bački Canal at Novi Sad. The canal is part of a system of waterways that links the Danube and Tisa rivers. Novi Sad also lies on the main highway and railroad between Belgrade and Budapest, Hungary. The city produces electrochemical equipment and processed foods. It is the home of the University of Novi Sad.

Novi Sad was founded in the early 1690's as the headquarters of the Serbian Orthodox Church. It grew as a trade center for the nearby farm area. A boom began in Novi Sad during the 1960's after petroleum and natural gas were found near the city.

Novocain. See Procaine.

Novosibirsk, NAW vah sih BEERSK(pop. 1,402,100), is an important center of manufacturing in Russia. The city lies on the Ob River, about 1,700 miles (2,740 kilometers) east of Moscow, in Siberia. Novosibirsk is the largest city in Siberia (see Russia [political map]). Many factories in Novosibirsk manufacture heavy equipment, including farm and mining machinery and diesel trucks. The city also produces steel, airlines, railroads, and riverboats serve Novosibirsk.

Novosibirsk was founded in 1893 as a settlement for workers building a railroad across Siberia. The city grew as a transportation center. Industry boomed during World War II (1939-1945), when many factories in combat areas in western areas of the country were moved to the safety of Novosibirsk. In 1958, the government built Akademgorodok (Academy City), a suburb of Novosibirsk, as a science research center.

Noyce, Robert (1927-1990), is one of the two inventors of the microchip, or integrated circuit. Such a chip contains all the components of an electronic circuit. Microchips are widely used in computers and other types of electronic equipment.

Noyce made his chip in 1959 while working at Fairchild Semiconductor Corporation, a company he helped found. Jack Kilby, an electrical engineer, developed a similar chip at about the same time, but working independently, Kilby's patent was filed first. But Noyce's design made the connections between components a part of the manufacturing process, while Kilby's did not.

In 1968, Noyce left Fairchild. He and Gordon Moore, a research scientist from Fairchild, founded Intel Corporation, now a leading manufacturer of semiconductor chips.

Robert Norton Noyce was born on Dec. 12, 1927, in Burlington, Iowa. He graduated from Grinnell College in 1949 and earned a doctorate in physics from Massachusetts Institute of Technology in 1953.

Paul N. Edwards

Noyes, noyz, Alfred (1880-1938), was one of the most popular English poets of the early 1900's. He became famous for his ballads and lyric poems about English history. Many of Noyes's poems also show his love of the sea. His reputation has declined since the mid-1900's, but some of his poetry remains popular with children, especially the exciting ballad 'The Highwayman' (1906).

Noyes was born on Sept. 16, 1880, in Wolverhampton. He established himself as a leading poet with the epic Drake (1906-1908). Drake deals with the famous English sea captain Sir Francis Drake. In The Golden Hynde (1908), Noyes filled his poems with colorful images of the sea and sea voyages. Tales of the Mermaid Tavern (1913) describes the adventures of noted Englishmen who lived during the reign of Queen Elizabeth I.

Noyes's most ambitious work was perhaps The Torchbearers, a long three-part poem. It honors the contributions of the great scientists of history. The poem consists of The Watchers of the Sky (1922), The Book of Earth (1925), and The Last Voyage (1930).

In 1927, Noyes converted to Roman Catholicism. His conversion influenced many of his later writings. In The Unknown God (1934), he wrote a prose account of his change from an unbeliever to a devout Christian.

In addition to verse, Noyes wrote biographies, literary criticism, novels, plays, and short stories. Some of his literary essays were collected in Pageant of Letters (1940). Noyes also wrote an autobiography, Two Worlds from Memory (1953).

Nubia, NOO bee uh, was a region of ancient Africa. It covered part of what is now Sudan. Nubia extended along the Nile River from the southern boundary of ancient Egypt almost to present-day Khartoum, Sudan.

The earliest Nubians were probably blacks. The Nubians were controlled by Egyptian rulers at times from about 2000 to 1000 B.C. The Egyptians regarded Nubia as a source of gold and as a trading center for cattle, ivory, and slaves from central Africa. Nubia's association with Egypt greatly influenced Nubian art and religion.

Kush, the most important civilization of Nubia, developed rapidly after 1000 B.C. This Nubian kingdom, which lasted until about A.D. 350, became a center of ironworking, learning, and trade. Kushites ruled Egypt from about 750 to 670 B.C. See Kush.

During the A.D. 500's, the people of Nubia were converted to Christianity. A large part of Nubia remained Christian until the 1300's, when Arab invaders conquered the region. They firmly established Islam, the religion of the Muslims.

John Middleton

Nuclear bomb. See Nuclear weapon.
A nuclear power plant uses the heat of a controlled nuclear reaction to produce steam, which then generates electric energy. The plant shown here, located southeast of Paris on the Seine River, has tall structures called cooling towers to dispose of excess heat.

Nuclear energy

Nuclear energy, also called atomic energy, is the powerful energy released by changes in the nucleus (core) of atoms. The heat and light of the sun result from nuclear energy. Scientists and engineers have found many uses for this energy, including the production of electric power, the explosion of nuclear weapons, and the diagnosis and treatment of medical conditions.

Scientists knew nothing about nuclear energy until the early 1900's, though they knew that all matter consists of atoms. Through further study, scientists learned that a nucleus makes up most of the mass (quantity of matter) of every atom and that this nucleus is held together by an extremely strong force. A huge amount of energy is concentrated in the nucleus because of this force. The next step was to make nuclei let go of much of that energy.

Scientists first released nuclear energy on a large scale at the University of Chicago in 1942, three years after World War II began. This achievement led to the development of the atomic bomb. The first atomic bomb was exploded in the desert near Alamogordo, New Mexico, on July 16, 1945. In August, United States airplanes dropped bombs on Hiroshima and Nagasaki, Japan. The bombs largely destroyed both cities and helped end World War II.

Since 1945, scientists have developed peaceful uses of nuclear energy. The energy released by nuclei creates large amounts of heat. This heat can be used to make steam, and the steam can be used to drive machines that generate electric power. Engineers have built devices called nuclear reactors to produce and control nuclear energy.

A nuclear reactor operates somewhat like a furnace. However, instead of using such fossil fuels as coal or oil, almost all reactors use uranium. And instead of burning in the reactor, the uranium fissions—that is, its nuclei split into two or more fragments. As a nucleus splits, it releases energy that is converted largely into heat. The fission of 1 pound of uranium releases more energy than the burning of 3 million pounds (1,500 tons) of coal. Stated in metric terms, the fission of 1 kilogram of uranium releases more energy than the burning of 3 million kilograms (3,000 metric tons, or 3 kilotons) of coal.

One important peaceful use of nuclear energy is the production of electric power. Nuclear energy also powers some submarines, surface ships, and spacecraft. Nuclear reactions also produce particles and rays called nuclear radiation that have uses in medicine, industry, and science. However, nuclear radiation can be extremely dangerous. Exposure to too much radiation can result in a condition called radiation sickness (see Radiation sickness).

The contributor of this article is Mirela Gavrila, Assistant Professor of Nuclear Engineering at the University of Maryland at College Park.
This article deals mainly with nuclear energy as a source of electric power. To learn about other uses of nuclear energy, see Nuclear weapon; Ship (Nuclear power and automation); Submarine.

The role of nuclear energy in power production

Almost all the world’s electric power is produced by hydroelectric and thermal power plants. Hydroelectric plants use the force of rushing water from a dam or waterfall to generate electric power. Thermal plants use the force of steam from boiling water. The great majority of thermal plants burn fossil fuels—coal, oil, and natural gas—to produce heat to boil water. The remaining thermal plants fission uranium.

Few countries have enough water power to generate large amounts of hydroelectric power, and many regions have already fully exploited their hydroelectric capacity. Most countries depend mainly on fossil fuels. But fossil fuels are a nonrenewable resource, and burning them produces gases that can damage the environment. Therefore, many experts predict that nuclear power will become increasingly important.

Worldwide use of nuclear energy. Nuclear power reactors produce electric power in more than 30 countries. There are more than 435 reactors worldwide. These reactors produce about 17 percent of the world’s electric power. The United States is the world’s leading producer of nuclear energy. In addition to these reactors, there are more than 3,000 nuclear facilities worldwide that are used for applications in research, medicine, industry, and agriculture.

Advantages and disadvantages of nuclear energy.

Nuclear power plants have two main advantages over fossil-fuel plants. (1) Once built, a nuclear plant can be less expensive to operate than a fossil-fuel plant, mainly because a nuclear plant uses a much smaller volume of fuel. (2) Uranium, unlike fossil fuels, releases no chemical or solid pollutants into the air during use.

However, nuclear power plants have three major disadvantages. These disadvantages have slowed the development of nuclear energy in some countries. (1) Nuclear power plants cost more to build than fossil-fuel plants. (2) Because of the need to assure that hazardous amounts of radioactive materials are not released, nuclear power plants must meet certain government regulations that fossil-fuel plants do not have to meet. For example, a nuclear plant must satisfy the government that it can quickly and automatically deal with any kind of emergency. (3) Used nuclear fuel produces dangerous radiation long after it has been removed from the reactor. As a result, safe disposal of nuclear waste presents a challenge.

The full development of nuclear energy. Many experts believe that the benefits of nuclear energy outweigh any problems involved in its production. According to these experts, oil may be so scarce by the mid-2000’s that it will be too expensive to drill. Canada, Germany, Russia, the United States, and some other countries have enough coal to meet their energy requirements for hundreds of years at present rates of use. However, coal releases large amounts of sulfur and other pollutants into the air when it is burned (see Environmental pollution). If nuclear energy were fully developed, it could completely replace oil and coal as a source of electric power.

But a number of problems must be solved before nuclear energy can be fully developed. For example, almost all today’s power reactors use a scarce type of uranium known as U-235. If U-235 continues to be used at

its present rate, the world's supply of it will become so small that it will be too expensive to mine and process by about 2050. Therefore, for nuclear energy to replace other energy sources, it must be based on fuel that is much more plentiful than U-235.

The composition of matter

The process by which a nucleus releases energy is called a nuclear reaction. To understand the various types of nuclear reactions, a person must know something about the nature of matter.

All the matter that makes up all solids, liquids, and gases is composed of chemical elements. The chemical elements, in turn, are composed of atoms. A chemical element consists of a substance that cannot be broken down chemically into simpler substances. There are 115 known chemical elements. Ninety-one of them are found on or in the earth. The other 24 are artificially created. However, one of these 24 elements, plutonium, occurs naturally in tiny amounts.

Scientists rank the elements according to mass, a measure of the quantity of matter in an object. An object's mass is proportional to its weight. Hydrogen is the lightest natural element, and uranium is the heaviest.

Most of the artificially created elements are heavier than uranium.

Atoms and nuclei. An atom consists of a positively charged nucleus and one or more electrons, which are negatively charged particles. The nucleus makes up almost all of an atom's mass. The electrons, which have almost no mass, revolve around the nucleus. Electrons determine the various chemical combinations that an atom enters into with other kinds of atoms (see Chemistry [Fundamental ideas of chemistry]). However, electrons do not play an active part in nuclear reactions.

The nuclei of every chemical element except hydrogen consist of particles called protons and neutrons. An ordinary nucleus of hydrogen, the lightest element, has one proton and no neutrons. The heaviest elements, such as uranium and thorium, have the largest number of protons and neutrons.

Protons carry a positive charge. Neutrons have no net charge. Extremely strong forces, called nuclear forces, hold the protons and neutrons together in the nucleus. The nuclear forces of each type of nucleus determine the amount of energy that would be required to release its neutrons and protons.

Isotopes. Most chemical elements have more than one form. These different forms are called the isotopes of an element. The atoms that make up each of the different forms have different mass numbers. The atoms are also called isotopes.

Mass number is the total number of neutrons and protons in the nucleus of an atom.

Neutron is an electrically neutral (uncharged) particle in a nucleus.

Nuclear radiation consists of high-energy particles and tiny packets of energy called photons that are given off during a nuclear reaction.

Nuclear reaction involves a change in the structure of a nucleus. Fission, fusion, and radioactive decay are the most important types of nuclear reactions.

Nuclear reactor is a device for producing nuclear energy by means of controlled chain reactions.

Nucleus is the core of an atom and carries a positive charge. The nuclei of all elements except hydrogen consist of neutrons and protons. An ordinary hydrogen nucleus has one proton and no neutrons.

Proton is a positively charged particle in a nucleus.

Radioactive decay, or radioactivity, is the process by which a nucleus spontaneously (naturally) changes into the nucleus of another isotope or element. The process releases energy mainly in the form of nuclear radiation.
Nuclear fission is the chief method of producing nuclear energy. It involves using a neutron to split a nucleus of a heavy element, such as uranium, into two fission fragments. Besides heat energy, fission releases neutrons and such radiation as gamma rays. The fragments give off beta particles and gamma rays. Comes another isotope of the same element.

Nuclear reactions

A nuclear reaction changes the structure of a nucleus. The nucleus gains or loses one or more neutrons or protons. It thus changes into the nucleus of a different isotope or element. If the nucleus changes into the nucleus of a different element, the change is called a transmutation (see Transmutation of elements).

Three types of nuclear reactions release useful amounts of energy. These reactions are (1) radioactive decay, (2) nuclear fission, and (3) nuclear fusion. During each reaction, the matter involved loses mass. The mass is lost because it changes into energy.

Radioactive decay, or radioactivity, is the process by which a nucleus changes into the nucleus of another isotope or element. The process releases energy chiefly in the form of particles and rays called nuclear radiation. Uranium, thorium, and several other elements decay naturally and so contribute to the natural, or background, radiation that is always present on the earth. Nuclear reactors produce radioactive isotopes artificially. Nuclear radiation accounts for about 10 percent of the energy produced in a reactor.

Nuclear radiation consists largely of alpha and beta particles and gamma rays. An alpha particle, which is made up of two protons and two neutrons, is identical with a helium nucleus. A beta particle is identical with an electron. It results from the breakdown of a neutron in a radioactive nucleus. The breakdown also produces a proton, which remains in the nucleus. Gamma rays are electromagnetic waves similar to photons or X rays (see Electromagnetic waves).

A chain reaction results in the continuous fissioning of nuclei and so produces a steady supply of energy. To produce a chain reaction, each fissioned nucleus must give off neutrons to fission at least two more nuclei, shown here. Uranium and plutonium are the materials used to produce a chain reaction.

Scientists measure the rate of radioactive decay in units of time called half-lives. A half-life equals the time required for half the atoms of a particular radioactive element or isotope to decay. Half-lives range from a fraction of a second to billions of years. See Isotope (Radioactive isotopes).

Nuclear fission is the splitting of heavy nuclei to release energy. All commercial nuclear reactors produce energy in this way. To produce fission, a reactor requires a bombarding particle, such as a neutron, and a target material, such as U-235. Nuclear fission occurs when the bombarding particle splits a nucleus in the target material into two or more parts called fission fragments. Each fragment consists of a nucleus with about half the neutrons and protons of the original nucleus. The energy is released in many forms. But most of the energy released by fission eventually takes the form of heat.

The bombarding particle must first be captured by a nucleus for fission to occur. Reactors use neutrons as bombarding particles because they are the only atomic particles that are both easily captured and able to cause fission. Neutrons can also pass through most kinds of matter, including uranium.

The target material. Commercial power reactors use uranium as their target material, or fuel. Uranium is abundant in nature and has one of the easiest nuclei to split because of its large number of protons. Protons naturally repel one another, and so a nucleus with many protons has a tendency to "fly apart." It can thus be split with little difficulty.

Uranium also makes a good nuclear reactor fuel because it can sustain a continuous series of fission reac-
ions. As a result, uranium can produce a steady supply of energy. To create a series of reactions, each fissioned nucleus gives off neutrons. Each of these neutrons can hit another uranium nucleus, thus releasing still more neutrons. As this process is repeated over and over, it becomes a self-sustaining chain reaction. Chain reactions can produce an enormous amount of energy. Only nuclei that have many more neutrons than protons, such as uranium nuclei, can produce a nuclear chain reaction. The scarce uranium isotope U-235 is the only natural material that nuclear reactors can use to produce a chain reaction. Nuclei of the much more abundant U-238 isotope usually absorb neutrons without fissioning. An absorbed neutron simply becomes part of the U-238 nucleus.

Neutrons released in fission travel too rapidly to be absorbed by U-235 nuclei in numbers large enough to sustain a chain reaction. Reactors can use U-235 as a fuel because they utilize other materials called moderators to slow the neutrons down. Some reactors use water as a moderator, while others use graphite or heavy water. Heavy water contains an isotope of hydrogen called deuterium in place of hydrogen. Deuterium is also known as heavy hydrogen.

The slowed neutrons travel at a velocity of about 2.2 kilometers per second and are known as thermal neutrons. Reactors that use moderators are called thermal reactors. Most of today's reactors are thermal reactors. Thermal neutrons are highly effective in causing fission in U-235. Therefore, the uranium in a thermal reactor can have a low percentage of U-235 content. Depending on their design, today's power reactors use a U-235 content ranging from 0.71 percent—the percentage in natural uranium—to almost 5 percent. Special purpose reactors may use fuel with a higher percentage of U-235.

Scientists have also developed fast reactors, in which high-velocity neutrons cause the fissions. These reactors use plutonium or uranium 233 fuel. Fast breeder reactors produce more fuel material than they consume. A fast breeder reactor that converts U-238 to plutonium can greatly extend the use of uranium as an energy resource. In addition, a fast reactor can be designed to consume certain radioactive elements that have long lives and are present in used fuel. Such a reactor would reduce the amount of certain radioactive wastes that must be disposed of. The section Research on new types of reactors in this article discusses fast reactors in more detail.

**Nuclear fusion** occurs when two lightweight nuclei combine and form a nucleus of a heavier element. The products of the fusion reaction have less mass than the original nuclei had. The lost mass has therefore been changed into energy.

Fusion reactions that produce large amounts of energy can be created by means of extremely intense heat. Such reactions are called thermonuclear reactions. Thermonuclear reactions produce the energy of both the sun and the hydrogen bomb.

A thermonuclear reaction can occur only in a form of matter called plasma. Plasma is a gaslike substance made up of free electrons and free nuclei (nuclei that have no electrons revolving about them). Normally, nuclei repel one another because of the positive charges of their protons. However, if a plasma containing lightweight atomic nuclei is heated many millions of degrees, the nuclei begin moving so fast that they overcome the force of repulsion and fuse. See Plasma (in physics).

**Problems of controlling fusion.** Scientists have not yet succeeded in harnessing the energy of fusion to produce electric power. In their fusion experiments, scientists generally work with plasmas that are made from the three isotopes of hydrogen—protium, deuterium, and tritium. The most common hydrogen isotope, protium, has a nucleus that consists of a single proton. Ordinary hydrogen is made almost entirely of protium. Deuterium is the second most common isotope. It has a nucleus made up of one proton and one neutron. The nucleus of the rarest isotope, tritium, consists of one proton and two neutrons. Tritium is not found in nature. Scientists produce tritium artificially by bombarding lithium nuclei with neutrons. Of the three isotopes of hydrogen, only tritium is radioactive.

A mixture of deuterium and tritium is an excellent thermonuclear fuel because ordinary seawater contains plentiful stocks of deuterium and lithium. One barrel of seawater contains enough of these substances to produce as much energy as the burning of about one-fifth of a barrel of oil.

To produce a controlled thermonuclear reaction, a plasma of one or more hydrogen isotopes must be heated many millions of degrees. But scientists have yet to develop a container that can hold plasma this hot. The plasma expands quickly. In addition, the walls of the container must be kept at low temperatures to prevent them from melting. But if the plasma touches the walls, it becomes too cool to produce fusion. The plasma must therefore be kept away from the walls of the container long enough for its nuclei to fuse and produce usable amounts of energy.

**Fusion devices.** Most experimental fusion reactors are designed to contain hot plasma in "magnetic bottles" twisted into various shapes. The walls of the bottles are made of copper or some other metal and are surround-
A nuclear power plant uses a nuclear reactor to convert water to steam. The steam drives turbogenerators that produce electric energy. This energy flows through wires to a switchyard, where other wires carry it from the plant. This plant uses a boiling water reactor, which produces steam inside its pressure vessel. After the steam drives the turbogenerators, it is cooled so that it turns back into water. This water is recirculated into the reactor. A steel and concrete containment vessel guards against the escape of radioactive material from an accidental leak in the reactor.

How nuclear energy is produced

All large commercial nuclear power plants produce energy by fissioning U-235. But U-235 makes up about 0.71 percent of the uranium found in nature. About 99.28 percent of all natural uranium is U-238. The two types occur together in uranium ores, such as carnottite and pitchblende. Separating the U-235 from the U-238 in these ores is difficult and costly. For this reason, the fuel used in reactors consists largely of U-238. But the fuel has enough U-235 to produce a chain reaction. Nuclear fuel requires special processing before and after it is used. The processing begins with the mining of uranium ore and ends with the disposal of fuel wastes.

This section deals chiefly with the methods used in the U.S. nuclear power industry. These methods resemble those used in other countries.

Power plant design. Most nuclear power plants cover an area of 200 to 300 acres (80 to 120 hectares). The majority are built near a large river or lake because nuclear plants require enormous quantities of water for cooling purposes.

A nuclear plant consists of several main buildings, one of which houses the reactor and its related parts. Another main building houses the plant’s turbines and electric generators. Every plant also has facilities for storing unused and used fuel. Many plants are largely automated. Each of these plants has a main control room, which may be in a separate building or in one of the main buildings.

The reactor building, or containment building, has a thick concrete floor and thick walls of steel or of concrete lined with steel. The concrete and steel guard against the escape of radioactive material from an accidental leak in the nuclear reactor.

Power reactors that are used in nuclear power plants in the United States consist of three main parts: (1) a reactor vessel, also called a pressure vessel; (2) a core; and (3) a set of control rods. In addition, reactor operations depend upon two substances—moderators and coolants.

The reactor vessel is a tanklike structure that encloses
the other main parts of the reactor. The vessel has steel walls that are typically at least 6 inches (15 centimeters) thick and capable of containing the high pressure exerted in a reactor.

The core contains the nuclear fuel, in which the fission chain reaction occurs. The core sits in the lower half of the reactor vessel. A great many fuel assemblies stand upright in the core between an upper and lower support plate. Each fuel assembly contains a bundle of fuel rods. A fuel rod consists of pellets of fuel inside a metal tube. The pellet material is usually a powder called uranium dioxide. The tubing material is typically zircalloy, a mixture of the metal zirconium and one or more other metals. Neutrons can pass from the fuel through the tube walls, but most other nuclear particles cannot.

The control rods are long metal rods that are used to regulate fission in the fuel. The control rods contain such neutron-absorbing materials as boron, cadmium, hafnium, or silver. A mechanism outside the reactor vessel is attached to the rods. This mechanism inserts the rods into the core and withdraws them when necessary. When inserted fully into the core, the control rods absorb many neutrons and so prevent a fission chain reaction from occurring. To begin operation of the reactor, the control rods are partially withdrawn until a chain reaction occurs at a constant rate. To increase power in the reactor, the rods are withdrawn slightly more. Thus, fewer neutrons are absorbed, and more are available to cause fission. To stop the chain reaction, the rods are inserted all the way into the core to absorb most of the neutrons.

The moderator is a substance that slows down neutrons as they pass through it. Slow neutrons are needed for fission in a nuclear reactor. The moderator fills the space between the fuel rods in the fuel assemblies. It

Parts of a nuclear reactor

![Diagram of a nuclear reactor](General Electric (WORLD BOOK diagram)]

The core is the heart of a nuclear reactor. Nuclear fuel in the core of this boiling water reactor produces heat that converts water to steam. The steam runs machinery outside the reactor. A pressure vessel encloses the core and various other equipment.

How a reactor works

![Diagram showing how a reactor works](General Electric (WORLD BOOK diagram)]

Fuel assemblies in the reactor's core hold individual fuel rods that contain atoms of nuclear fuel. As the fuel nuclei split, they produce energy and release neutrons. Other fuel nuclei split when struck by the neutrons, and thus the reaction continues.

Control rods limit the number of fuel nuclei that can split. Materials in the rods absorb neutrons. When fully inserted in the core, the rods absorb so many neutrons that few nuclei can split. To start the reactor, some rods are partly withdrawn.
sloths down neutrons as they pass from one fuel rod to another.

The coolant is a liquid or gas that carries off the heat created by the fission chain reaction. The coolant circulates throughout the core. It carries the heat from the reactor to an energy conversion system. Thus the coolant keeps the fuel and cladding from getting too hot, and it transfers energy to a place where electric power can be generated.

All commercial power reactors in the United States are light water reactors. In these devices, light (ordinary) water serves as the moderator and the coolant. Canadian reactors are heavy water reactors. They use heavy water as the moderator and the coolant. Heavy water contains deuterium in place of ordinary hydrogen. For more information on reactors, see the section Research on new types of reactors in this article.

**Fuel preparation.** After uranium ore has been mined, it goes through a long milling and refining process to separate the uranium from other elements in the ore. Light water absorbs more neutrons than do other types of moderators. The uranium used in light water reactors must therefore be enriched—that is, the percentage of U-235 must be increased. Neutrons then have a better chance of striking a U-235 nucleus. In the United States, uranium that has been separated from the ore is sent to an enrichment plant.

Enrichment plants increase the proportion of U-235 in the uranium, depending on the intended use of the uranium. Most light water reactors use fuel with about 2 to 4 percent U-235. Much higher amounts of U-235 are needed in nuclear weapons and in the fuel for nuclear ships. The enriched uranium used as reactor fuel is shipped to fuel fabrication plants.

A fuel fabrication plant changes enriched uranium into uranium dioxide. The plant then shapes the uranium dioxide powder into pellets about \( \frac{1}{8} \) inch (18 millimeters) in diameter and \( \frac{1}{8} \) inch (13 millimeters) long. The pellets are inserted into tubes made of zircalloy. Each tube measures about \( \frac{1}{8} \) inch (13 millimeters) in diameter and 10 to 14 feet (3 to 5 meters) long.

After a tube has been filled with uranium dioxide pellets, its ends are welded shut. This sealed tube is called cladding. These fuel rods are then fastened together into bundles of 30 to 300 each. Each bundle, or fuel assembly, weighs 300 to 1,500 pounds (140 to 680 kilograms). Commercial power reactors need 50 to 150 tons (45 to 136 metric tons) of uranium dioxide. The amount depends on the size of the reactor.

**Chain reactions.** A reactor requires a certain minimum amount of fuel to keep up a chain reaction. This amount, called the critical mass, varies according to the design and size of the reactor. Reactors are designed to hold more than a critical mass of fuel to allow for fuel use during operation. The position of the control rods determines the effective mass of the fuel, the amount of fuel taking part in the chain reaction. If the effective mass is decreased below the critical mass, the chain re-
tion will die out and reactor power will decrease. If the effective mass is increased above the critical mass, the chain reaction will become more rapid and reactor power will increase. In an emergency, if the chain reaction became too rapid, the reactor could overheat. However, the control rods are available to slow down the chain reaction if it becomes too rapid.

To prepare a reactor for operation, the fuel assemblies are loaded into the core with the control rods completely inserted. In a light water reactor, the water serves as a moderator to slow down the neutrons that fill the spaces between the fuel assemblies. The control rods are then slowly withdrawn, and a chain reaction begins. The farther the rods are withdrawn, the greater the rate of the reaction because fewer neutrons are absorbed. More neutrons thus are available to cause fission. When the desired power is reached, the control rods are positioned so that the effective mass is equal to the critical mass. The water in the core carries off the heat created by the chain reaction. To stop the reaction, the rods are gain inserted all the way into the core to absorb most neutrons.

Steam production. The light water reactors used by almost all U.S. nuclear plants are of two main types. One type, the pressurized water reactor, produces steam outside the reactor vessel. The other type, the boiling water reactor, makes steam inside the vessel.

Most nuclear plants in the United States use pressurized water reactors. These reactors heat the moderator water in the core under extremely high pressure. The pressure allows the water to heat past its normal boiling point of 212 °F (100 °C) without actually boiling. The chain reaction heats the water to about 600 °F (315 °C). Pipes carry this extremely hot, though not boiling, water to steam generators outside the reactor. These generators transfer heat from the pressurized water to a separate supply of water that boils and so produces steam.

In a boiling water reactor, the chain reaction boils the moderator water in the core. Steam is therefore produced inside the reactor vessel. Pipes carry the steam from the reactor to the plant's turbines.

In producing electric energy, a nuclear plant's steam turbines and electric generators work like those in a fossil-fuel plant. The steam produced by a reactor spins the blades of the plant's turbines, which drive the generators. Many plants have combination turbines and generators called turbogenerators.

After steam has passed through a plant's turbines, it is piped to a condenser. The condenser changes the steam back into water. A reactor can thus use the same water over and over. But a condenser requires a constant supply of fresh water to cool the steam. Most plants pump this water from a nearby river or lake. The water, which becomes warm as it passes through the condenser, is then pumped back into the river or lake. This warm wastewater may heat the water in the river or lake enough to endanger plants and animals that live there.

For this reason, the discharge of the wastewater is sometimes called thermal pollution.

To help solve the problem of thermal pollution, most new nuclear plants have cooling towers. Hot water from the steam condensers is moved through the towers in such a way that the heat passes into the atmosphere. The cooled water is returned to the steam condenser for reuse.

Hazard and safeguards. An ordinary power reactor cannot explode like an atomic bomb. Only a greatly supercritical mass of plutonium 239 or of highly enriched uranium 235 can explode in this way. A supercritical mass contains more than the amount of plutonium or uranium required to sustain a chain reaction.

The chief hazards of nuclear power production result from the great quantities of radioactive material that a reactor produces. These materials give off radiation in the form of alpha and beta particles and gamma rays. The reactor vessel is surrounded by thick concrete
blocks called a shield, which normally prevents almost all radiation from escaping.

Federal regulations limit the amount of radiation allowed from U.S. nuclear plants. Every plant has instruments that continually measure the radioactivity in and around the plant. They automatically set off an alarm if the radioactivity rises above a predetermined level. If necessary, the reactor is shut down.

A plant’s routine safety measures greatly reduce the possibility of a serious accident. Nevertheless, every plant has emergency safety systems. Possible emergencies range from a break in a reactor water pipe to a leak of radiation from the reactor vessel. Any such emergency automatically activates a system that instantly shuts down the reactor, a process called scramming. The usual method of scramming is to insert the control rods rapidly into the core.

A leak or break in a reactor water pipe could have dangerous consequences if it results in a loss of coolant. Even after a reactor has been shut down, the radioactive materials remaining in the reactor core can become so hot without sufficient coolant that the core melts. This condition, called a meltdown, could result in the release of dangerous amounts of radiation. In most cases, the large containment structure that houses a reactor would prevent radioactive material from escaping into the atmosphere. To prevent such an accident from occurring, all reactors are equipped with an emergency core cooling system, which automatically floods the core with water in case of a loss of coolant.

Wastes and waste disposal. The fissioning of U-235 produces more neutrons than are needed to continue a chain reaction. Some of them combine with U-238 nuclei, which far outnumber U-235 nuclei in the reactor fuel. When U-238 captures a neutron, it is changed into U-239. The U-239 then decays into neptunium 239 (Np-239), which decays into plutonium 239 (Pu-239). This same process forms Pu-239 in a breeder reactor. Slow neutrons can fission Pu-239, as well as U-235. Some of the newly formed Pu-239 is thus fissioned during the fissioning of U-235. The rest of the Pu-239 remains in the fuel assemblies.

The fissioning of U-235 also produces many other radioactive isotopes, such as strontium 90, cesium 137, and barium 140. Fuel wastes can remain dangerously radioactive for about 600 years because of the strontium and cesium isotopes. After that time, enough of the strontium and cesium will have decayed into stable isotopes so that they no longer present a severe problem. However, the plutonium and other artificially created elements in the wastes remain radioactive for thousands of years. Even in small amounts, plutonium can cause cancer or genetic damage in human beings. Larger amounts can cause radiation sickness and death (see Radiation sickness). Safe disposal of these wastes is one of the most difficult problems involved in nuclear power.

Most nuclear plants need to replace their fuel assemblies only about once a year. The radioactive wastes generate heat, and so used fuel assemblies must be cooled after removal from a reactor. Nuclear plants cool the assemblies by storing them underwater in specially designed storage pools.

In the United States, the federal government is working on guidelines for the safe and permanent disposal of nuclear wastes. The current U.S. plan calls for isolating long-lived radioactive waste from the environment in underground storage sites. A law passed by Congress in 1982 required the federal government to build two sites for nuclear wastes from commercial power plants. In 1987, the law was changed to require a single site.

A storage site for nuclear waste must lie in a highly stable area that is free of earthquakes, faulting, and other geologic activity. The site must be dry so that the waste containers cannot be corroded and water supplies cannot be contaminated. The site also must be constructed so that future generations do not dig into it and release radioactivity. The government has for several years been studying the suitability of a location in

The main control room of a nuclear power plant contains a variety of computers, switches, recorders, and other devices. Some of these devices help regulate the production of nuclear energy. Others monitor the plant's safety systems.
levada. In the meantime, commercial nuclear power plants in the United States continue to store used fuel ensembles and other wastes in pools of water on the plant grounds.

Other countries, including Japan, Russia, and the United Kingdom, are pursuing a reprocessing plan. Under this plan, nuclear plants would ship their used fuel ensembles to the reprocessing plants for removal of Pu-239 and unused U-235. These radioactive isotopes could then be recycled into fuel for nuclear reactors. However, this method would leave radioactive isotopes in the chemical solutions used for reprocessing. These solutions would have to be changed into a solid form that could be safely stored.

The nuclear energy industry

In every country that has a nuclear energy industry, the government plays a role in the industry. But the government's role varies greatly among countries. This section deals mainly with the U.S. and Canadian nuclear energy industries.

Organization of the industry. Private utility companies own most of the nuclear power plants in the United States. The rest are publicly owned. Private companies also manufacture reactors, mine uranium, and handle most other aspects of U.S. nuclear power production.

Canada's nuclear power plants are all publicly owned. Atomic Energy of Canada Limited (AECL), a government corporation, has overall responsibility for the country's nuclear research and development program. AECL also designs the CANDU (Canada Deuterium oxide-Uranium) light water reactors used by all Canadian nuclear plants. Private companies make the various reactor parts and mine and process the country's uranium. Canada has no uranium enrichment plants because CANDU reactors operate with unenriched uranium fuel.

The industry and the economy. The main economic advantage of nuclear power plants is that this fuel is less expensive than fossil fuels. But nuclear plants cost somewhat more to build than do fossil-fuel plants.

Under normal economic conditions, a nuclear plant's savings in fuel eventually make up for its higher construction expenses. At first, these expenses add to the cost of producing electric power. But after some years, a plant will have paid off its construction costs. It can then produce electric power more cheaply than a fossil-fuel plant can.

The industry and the environment. Unlike fossil-fuel plants, nuclear plants do not release solid or chemical pollutants into the atmosphere. For this reason, nuclear power is expected to play a major role in enabling several countries to meet the objectives of the Kyoto protocol, a 1997 agreement calling for reduced emissions of various heat-trapping gases. However, a nuclear plant releases small amounts of radioactive gas into the air. In addition, the cooling water used in pressurized water reactors picks up a small amount of radioactive tritium in the steam condenser. The tritium remains in this water when it is returned to a river or lake. But these small amounts of radiation released into the environment are not believed to be harmful. Thermal pollution remains a problem at some nuclear plants. But cooling towers help correct this problem.

In a small number of nuclear accidents, hazardous amounts of radiation have been released into the atmosphere. Accidental releases of radioactive substances have occurred in Russia, the United States, and the United Kingdom; and an especially serious accident occurred in 1986 at the Chernobyl nuclear power plant in Ukraine (then part of the Soviet Union). The subsection Hazards and safeguards that appears earlier in this article discusses the main methods of guarding against accidents.

Critics of nuclear power also fear another danger to the environment. As power production increases, the creation of high-level radioactive wastes also increases. The problem of storing radioactive wastes is discussed in the subsection Wastes and waste disposal.

Government regulation. The Nuclear Regulatory Commission (NRC), an agency of the federal government, regulates nonmilitary nuclear power production in the United States. One of the NRC's main duties is to ensure that nuclear power plants operate safely, and it makes and enforces a variety of safety standards. Every nuclear reactor and power plant must be inspected and licensed by the NRC before it may begin operations. The NRC also supervises the manufacture and distribution of nuclear fuels, and controls the disposal of radioactive wastes from commercial production.

The Atomic Energy Control Board, a Canadian government agency, regulates Canada's nuclear energy industry. The board's duties resemble those of the Nuclear Regulatory Commission.

Careers in nuclear energy cover a wide range of occupations and require widely varying amounts of training. A high percentage of the jobs require a college degree or extensive technical education. Many of these jobs are in large research laboratories, which work to improve nuclear processes and to lessen their hazards. Other careers requiring advanced training are in such areas as uranium mining and processing, reactor manufacturing and inspection, power plant operation, and government regulation.

Many colleges and universities offer undergraduate and graduate degrees in such highly specialized fields as nuclear engineering, nuclear physics, and nuclear technology. The industry also employs many workers with college degrees in various branches of engineering and in such fields as biology, chemistry, geology, and medicine. Many vocational and technical schools and some high schools prepare students for specialized jobs in the industry.

The development of nuclear energy

In 1972, scientists discovered that a natural chain reaction had released nuclear energy nearly 2 billion years ago in a uranium deposit in west-central Africa. Two billion years ago, there had been so little radioactive decay that the ore contained enough U-235 for a chain reaction. An accumulation of ground water acted as a moderator to begin the reaction. As heat from the reaction changed the water into steam, less and less water was available to serve as a moderator and the reaction died out. Except for such rare natural occurrences, nuclear energy was not released on a large scale on the earth until 1942. That year, scientists produced the first artificially created chain reaction. Scientific discoveries that have taken place since the late 1800's have led to the
large-scale release of nuclear energy.

**Early developments.** Before the late 1800's, scientists did not suspect that atoms could release nuclear energy. Then in 1896, the French physicist Antoine Henri Becquerel found that uranium constantly gives off energy in the form of invisible rays. He thus became the discoverer of radioactivity. Other scientists soon began experiments to learn more about this mysterious phenomenon.

The beginning of nuclear physics. In 1898, the great New Zealand-born physicist Ernest Rutherford identified two kinds of radioactive "rays," which he called alpha rays and beta rays. He and other researchers later showed that these rays are actually high-energy particles, which became known as alpha and beta particles. Experiments with these particles then led Rutherford to discover the atom's nucleus. This achievement, which Rutherford announced in 1911, marked the beginning of a new science—nuclear physics.

About 1914, scientists began doing experiments to see what happens when nuclear particles collide. The scientists used alpha particles from naturally radioactive materials to bombard the nuclei of light atoms. Light nuclei do not repel positively charged particles, such as alpha particles, as strongly as heavy nuclei do. Rutherford used this method to produce the first artificial transmutations in a series of experiments from 1917 to 1919. He bombarded nitrogen atoms with alpha particles. In rare collisions, a nitrogen 14 nucleus absorbed an alpha particle (a helium 4 nucleus). At the same time, the alpha particle pushed a proton out of the nitrogen nucleus. The nucleus thereby became an oxygen 17 nucleus.

Artificial fission. To produce nuclear reactions in heavy nuclei, scientists needed a particle that heavy nuclei would not repel. In 1932, the British physicist James Chadwick discovered such a particle—the neutron. In 1938, two German radiochemists, Otto Hahn and Fritz Strassmann, reported they had produced the element barium by bombarding uranium with neutrons.

At first, scientists could not explain how uranium had produced barium, which is much lighter than uranium. All previous transmutations had resulted in an element about as heavy as the original one. Then in 1939, the Austrian physicist Lise Meitner and her nephew Otto Frisch showed that Hahn and Strassmann had in fact produced the first known artificial fission reaction. A uranium nucleus had split into two nearly equal fragments, one of which consisted of a barium nucleus. Two neutrons were also emitted. The other fragment consisted of a nucleus of krypton, a somewhat lighter element than barium. These two nuclei, together with the emitted neutrons, are lighter than a uranium nucleus and a neutron. The reaction had therefore produced more energy than it consumed.

Scientists soon realized that if many uranium nuclei could be made to fission, a tremendous amount of energy would be released. The amount of energy could be calculated from a theory developed by the great German-born physicist Albert Einstein in 1905. The theory shows that matter can change into energy and that matter and energy are related by the equation \( E = mc^2 \). This equation states that the energy \( E \) (into which a given amount of matter can change equals the mass \( m \) of that matter multiplied by the speed of light squared \( c^2 \)). The speed of light squared is obtained by multiplying the speed of light by itself. Using this equation, scientists determined that the fissioning of 1 pound (0.45 kilogram) of uranium would release as much energy as 8,000 tons (7,300 metric tons) of TNT. Uranium could therefore be used to make a powerful bomb.

The development of nuclear weapons. World War II broke out in Europe in September 1939. The month before, Einstein had written to U.S. President Franklin D. Roosevelt urging him to commit the United States to developing an atomic bomb. Einstein had fled to the United States from Germany to escape Nazi persecution. He warned Roosevelt that German scientists might already be working on a nuclear bomb. Roosevelt acted on Einstein's urging, and early in 1940 scientists receive the first funds for uranium research in the United States.

The first nuclear reactor was built by scientists at the University of Chicago beneath the stands of the university's athletic field. The reactor, made of tons of uranium oxide and uranium embedded in graphite, produced the first artificial chain reaction in 1942.
The United States entered World War II in 1941. The government then ordered an all-out effort to build an atomic bomb and in 1942 established the top-secret Manhattan Project to achieve this goal (see Manhattan Project).

A group of scientists at the University of Chicago had charge of producing plutonium for the Manhattan Project. The group included such noted physicists as Enrico Fermi, Leo Szilard, and Eugene Wigner, all of whom had been born in Europe and had settled in the United States. Fermi headed the group. Under the scientists' direction, workers built an atomic pile, or reactor, beneath the stands of the university athletic field. The pile consisted of 50 tons (45 metric tons) of natural uranium oxide and uranium embedded in 500 tons (450 metric tons) of graphite. The graphite served as a moderator. The pile was designed to demonstrate a controlled nuclear chain reaction in the uranium. Cadmium rods controlled the reaction. On Dec. 2, 1942, this reactor produced the first artificial chain reaction.

The success of the University of Chicago project led the U.S. government to build a plutonium-producing plant in Hanford, Washington. The government also built a uranium enrichment plant in Oak Ridge, Tennessee. Plutonium and greatly enriched uranium from these plants were used in the two atomic bombs that the United States dropped on Japan in August 1945.

After World War II, scientists began work on developing a hydrogen bomb. The United States exploded the first hydrogen bomb in 1952 and so achieved the world's first large-scale thermonuclear reaction. The Soviet Union tested its first atomic bomb in 1949 and its first full-scale hydrogen bomb in 1953. China, France, India, Pakistan, South Africa, and the United Kingdom have also exploded nuclear weapons. For more information on the development of nuclear weapons, see Nuclear weapon.

The first peaceful uses. While research on nuclear weapons continued, various countries also began experimenting with nuclear reactors. The United States and the Soviet Union had built uranium enrichment plants for nuclear weapons. Both countries therefore started to develop light water reactors, which require enriched uranium fuel. Canada, France, and the United Kingdom worked on reactors moderated by graphite or heavy water. These reactors cost more to build than light water reactors but use unenriched uranium.

The U.S. Congress set up the Atomic Energy Commission (AEC) in 1946 to direct and control all aspects of nuclear energy development in the United States. In 1954, Congress allowed private industry to take over most aspects of commercial nuclear power development. But the AEC became responsible for regulating the nuclear energy industry. It also kept control in such areas as uranium enrichment and waste disposal.

The United States made the world's first full-scale use of controlled nuclear energy in 1954. That year, the U.S. Navy launched the first nuclear-powered vessel, the submarine Nautilus. The world's first full-scale nuclear power plant began operations in 1956 at Calder Hall in northwestern England. In 1957, the first large-scale nuclear plant in the United States opened in Shippingport, Pennsylvania. It supplied electric power to the Pittsburgh area until 1982, when the plant was closed. Canada opened its first full-scale plant in 1962 at Rolphston, Ontario.

The successful start of the nuclear power industry convinced world leaders of the need for international cooperation in the field. In 1957, the United Nations (UN) established the International Atomic Energy Agency to promote the peaceful uses of nuclear energy (see International Atomic Energy Agency; United Nations [Peaceful uses of nuclear energy]). Also in 1957, Belgium, France, Italy, Luxembourg, the Netherlands, and West Germany formed the European Atomic Energy Community (EURATOM). The organization encourages the development of nuclear power among its member countries. Today, the countries that make up the European Union are all members of EURATOM (see European Union).

The spread of nuclear capability. During the 1960s and early 1970s, a number of countries acquired reactors and used them to start nuclear power development. Progress was also made during this period toward limiting nuclear weapons tests and stopping the spread of nuclear weapons. In 1970, for example, a nuclear nonproliferation treaty went into effect. The treaty prohibits the nuclear powers that have agreed to abide by the document from giving nuclear weapons to nations that do not already have them. The nonproliferation treaty also prohibits nations without nuclear weapons from acquiring them.

But the nonproliferation treaty does not prohibit nations from selling or buying nuclear reactors. A reactor can be used not only for peaceful purposes but also to produce plutonium for nuclear weapons. India used a research reactor for this purpose and in 1974 exploded its first atomic bomb. Canada had supplied the reactor to India with the understanding it would be used for peaceful purposes only. Canada has signed the nonproliferation treaty, but India has not. Critics of India's action question the wisdom of supplying reactors to countries that do not already have them.

Meanwhile, the United States had been greatly increasing its nuclear power capacity. But opposition to nuclear power development also increased in the United States during the late 1960s and early 1970s. Critics began to question nearly every aspect of nuclear power production, from the cost of uranium enrichment to the problems of waste disposal.

Many critics of the United States nuclear program charged that the government overlooked various safety risks at nuclear plants to promote nuclear power development. Partly as a result of such criticism, Congress disbanded the Atomic Energy Commission (AEC) in 1974 and divided its functions between two newly formed agencies. The Energy Research and Development Administration (ERDA) took over the AEC's development programs. The Nuclear Regulatory Commission (NRC) took over its regulatory duties. The NRC, it was believed, could better regulate the industry if it was not also responsible for the industry's growth and development. In 1977, Congress abolished ERDA and transferred its responsibilities to the newly created Department of Energy. See Energy, Department of; Nuclear Regulatory Commission.

In 1992, the U.S. Congress passed the Energy Policy Act, opening the way for deregulation of the electric power industry. Since then, many nuclear utilities have
consolidated. In 2000, the NRC began approving extensions of operating life for existing nuclear plants.

**Safety concerns.** There have been a number of accidents at nuclear power plants. Most have not been serious. However, in 1957, a fire at the Windscale plutonium production plant in northern England resulted in the release of a large quantity of radioactivity. The British government banned the sale of milk from cows in that part of England for more than a month after the fire.

In the United States, concerns about the safety of nuclear reactors increased after a serious accident in 1979 at the Three Mile Island nuclear power plant near Harrisburg, Pennsylvania. Mechanical and human failures resulted in a breakdown of the reactor's cooling system and the destruction of the reactor core. Scientists and technicians prevented a failure of the reactor vessel that might have released large amounts of radioactive isotopes into the reactor containment building. Cleanup of the plant was completed in the early 1990’s.

The worst nuclear accident in history occurred in 1986 at the Chernobyl nuclear power plant near Kiev in Ukraine, which was then part of the Soviet Union. An explosion and fire ripped apart the reactor and released large amounts of radioactive isotopes into the atmosphere. Unlike most Western reactors, the Chernobyl reactors lacked an enclosure to prevent radioactive isotopes from escaping. Soviet officials reported that 31 people died from radiation sickness or burns and more than 200 others were seriously injured. The radioactive substances spread over parts of what are now Ukraine, Russia, and Belarus, and were carried by wind into northern and central Europe. Experts expected a significant increase in the number of cancer deaths among those near the reactor. But they predicted that the health effects outside the area would be slight. The last working reactor at Chernobyl was shut down in 2000.

As a result of the accidents at Three Mile Island and Chernobyl, opposition to nuclear power increased in many countries during the late 1980’s. In the United States, the NRC tightened its control of nuclear plants.

Experts have expressed particular concern over the safety of older Soviet-designed reactors now operating in Russia, Ukraine, and several countries of the former Soviet bloc. Western scientists and engineers are helping to remedy some of the most urgent safety problems in these reactors.

As the nuclear power industry has continued to develop, many improvements in plant equipment and operation have increased safety. Nonetheless, some experts insist that the next generation of reactors should take greater advantage of design features that rely less—or not at all—on mechanical equipment such as pumps and valves to remove heat if an accident occurs. Some of these reactors are known as passively safe reactors. The following section on **Research on new types of reactors** describes some of these proposed reactors.

**Research on new types of reactors.** New research on reactors was sparked by fears of a shortage of U-235 to fuel fission reactors. However, during the 1970’s nuclear power production increased less rapidly than expected. Geologists also discovered that there was much more uranium on earth than had originally been estimated. Therefore, the expected near-term shortage did not occur.

Today, scientists seek to develop safer and more efficient reactors. Researchers have concentrated their efforts on the development of a fusion reactor and advanced fission reactors.

**Experimental fusion devices.** Most experiments on controlled nuclear fusion have concentrated on the de-
A tokamak fusion reactor heats hydrogen nuclei so that they fuse (join), releasing energy. Researchers are trying to develop a fusion reactor that can produce commercially valuable amounts of energy.

A tokamak is a chamber, being examined here by a worker, in which hydrogen nuclei are forced to fuse. The tokamak produces fusion by heating a plasma (a mixture of nuclei and electrons) to at least 180,000,000 °F (100,000,000 °C).

One goal of fusion research is to reach the breakeven level, the level of energy production equal to the energy needed to create and heat the plasma. To reach this level, a tokamak of the design presently under development must heat the plasma to at least 180,000,000 °F (100,000,000 °C). Also, each cubic centimeter (0.061 cubic inch) of the plasma must contain about 100 trillion nuclei, and the magnetic field must confine the plasma for about 1 second.

Researchers working with tokamaks have reached three goals, but never in the same experiment. By mid-1990, individual experiments on plasmas made up of deuterium and tritium atoms had achieved about 30 percent of the breakeven level.

Another kind of fusion reactor uses inertial confinement. In this case, no container holds the fuel during fusion. Rather, the fuel's inertia, its natural tendency to remain in the same place, holds it long enough for fusion to occur. In one kind of inertial confinement fusion (ICF) reactor, extremely powerful laser beams strike a cylindrical case made of metal. Inside the case is a pea-sized sphere containing deuterium and tritium gas. The laser beams heat the case, causing it to turn to plasma. The plasma, in turn, bombards the sphere with X rays, rapidly heating the shell of the sphere. As a result, the shell both expands and pushes inward. The inward push compresses the fuel, causing fusion.

The most powerful laser-driven reactor was the Nova device at Lawrence Livermore National Laboratory in Livermore, California. Nova operated from 1985 to 1999. At its peak power, Nova could deliver up to 40,000 joules of energy in a pulse lasting 1 billionth of a second. One joule is the amount of work done when a force of 1 newton moves an object 1 meter in the direction of the force.
An inertial confinement fusion reactor heats a target so rapidly that nuclei fuse before the target can fly apart. Laser beams hit a target in a spherical chamber, above, producing X rays. The rays strike a hydrogen-filled pellet, right, vaporizing its shell and compressing the hydrogen. The hydrogen becomes so hot that nuclei fuse.

Advanced fission reactors. Research, development, and design work on advanced fission reactors has concentrated on advanced versions of today's light-water reactors (LWR's), other types of advanced thermal reactors, and fast reactors. The goals of this work include improved operating efficiency, simplified design, lower cost, and increased use of passive safety systems. A passive safety system is one that does not depend upon mechanical devices, such as pumps and valves, to prevent core damage and remove heat from the core if an accident occurs.

A type of fission reactor that is currently operating in Japan—and which the NRC has certified for use in the United States—is the advanced light water reactor (ALWR). Many ALWR's are smaller than today's LWR's, and they have many passive safety features. One ALWR design relies on gravity, rather than pumps, to circulate a supply of cooling water that would be needed in certain emergencies.

A high-temperature gas-cooled reactor (HTGR) is a small unit that uses a gas, usually helium, as the coolant. The fuel consists of ceramic-coated pellets of uranium oxycarbide. The purpose of this design is to make it impossible for the fissions in a pellet to produce enough heat to rupture the casing, even if the reactor were to lose all its coolant. If the pellets remained intact, radioactive material would not be released.

A group of reactors known as fast reactors have long-term advantages. A fast breeder reactor can be designed to both consume plutonium as a fuel and convert U-238 to more plutonium. The new plutonium, in turn, can be used as reactor fuel. The breeder thus creates more fissionable material than it consumes. Because uranium is plentiful, the use of breeders would extend its potential as an energy resource enormously. Several countries have built experimental breeders. A unit in France, called the Superphénix, is the most powerful. It can produce 1,200,000 kilowatts of electric power.

Fast reactors can also be developed to consume some of the long-lived radioactive materials, such as plutonium and americium, in spent fuel, thus avoiding
the need to contain these materials in a repository for thousands of years.

Other scientists make use of the fact that radioisotopes decay at an exact and uniform rate. One application, known as radiocarbon dating, uses the rate of decay of a carbon isotope to determine the age of ancient plants and animals.

Fission creates energy in a nuclear power plant. In this process, a heavy nucleus, such as a uranium nucleus, absorbs a subatomic particle, then splits into two smaller nuclei. In each fission, a tiny amount of nuclear matter changes into heat energy. Electric generators in the power plant convert the heat to electric energy.

Fusion powers the sun and other stars. In one kind of fusion reaction, two protons come together. One of them emits a positively charged particle called a positron and a neutral particle known as a neutrino. The emissions turn the proton into a neutron, so the resulting nucleus consists of a proton and a neutron. During fusion, some nuclear matter changes into heat energy. Scientists are experimenting with ways to produce electric energy from the energy of fusion.

Nuclear power. See Nuclear energy.

Nuclear reactor is a device in which controlled nuclear fission reactions take place. See Isotope (Artificial radioisotopes); Nuclear energy (Power reactors); Rocket (Nuclear rockets; picture); Submarine (The power plant; pictures).

Nuclear Regulatory Commission is an independent agency of the United States government. The commission, also called the NRC, was organized to ensure that the use of nuclear energy for civilian purposes does not endanger the health and safety of the public and the environment. It licenses and oversees the construction and operation of nuclear reactors that produce electric power. The NRC also regulates the use of radioactive materials in agriculture, industry, and medicine, and the packaging of such materials for transport.

The Energy Reorganization Act of 1974 abolished the Atomic Energy Commission (AEC) and replaced it with the NRC and the Energy Research and Development Administration (ERDA). The NRC began operations in 1973. In 1977, ERDA was abolished and its responsibilities were transferred to the Department of Energy.

Critically reviewed by the Nuclear Regulatory Commission

Nuclear waste. See Nuclear energy (Wastes and waste disposal).

Nuclear weapon is any weapon that gets its destructive power from the transformation of matter in atoms into energy. All nuclear weapons are explosive devices. They are carried in missiles, bombs, artillery shells, mines, or torpedoes. The most powerful nuclear weapons are far more destructive than any conventional (non-nuclear) weapon.

Nuclear weapons can be fission weapons, also called atomic bombs or atomic weapons, or they can be thermonuclear weapons, also known as hydrogen bombs, hydrogen weapons, or fusion weapons. In fission weapons, matter converts to energy when the nuclei (cores) of certain kinds of uranium or plutonium atoms are split. Thermonuclear weapons convert matter to energy by combining pairs of certain kinds of hydrogen nuclei to form single nuclei. Thermonuclear weapons are generally far more powerful than fission weapons. Most nuclear weapons are thermonuclear.

The first nuclear weapons were two fission bombs dropped by the United States on the Japanese cities of Hiroshima and Nagasaki during World War II (1939-1945). The bombs killed from 110,000 to 140,000 people and destroyed large areas of both cities. The terrible destruction caused by the bombs became a major factor in Japan's decision to surrender to the United States and its Allies. Japan's surrender ended the war. The bombs exploded at Hiroshima and Nagasaki are the only two nuclear weapons that have ever been used.

Most experts believe that the threat of nuclear war probably helped keep the peace during the Cold War, a period of intense hostility between Communist and non-Communist nations, and their respective allies, following World War II. To avoid the terrible damage that nuclear weapons could cause, many nations have long sought ways to control such weapons and reduce the risk of nuclear war.

The United States and Russia have most of the world's nuclear weapons. The United Kingdom and France also developed small, potent arsenals (supplies) of nuclear weapons during the Cold War. Other countries that possess nuclear arms include China, India, Pakistan, and South Africa. Several other nations may have the ability to build nuclear weapons.

The growing number of nuclear powers increases the danger that regional tensions could possibly lead to the use of nuclear weapons. An example of such tensions was a crisis between India and Pakistan in the disputed region of Kashmir in 2002. Troops on both sides exchanged artillery fire, and the two countries, both with nuclear weapons, seemed on the brink of war. Tensions also run high in the Middle East. Many experts believe the Middle Eastern nations of Israel, Iraq, and Iran either possess or are close to building nuclear weapons. Other threats may involve terrorist groups without governmental ties that could acquire and use nuclear devices.

How nuclear weapons work

Fission weapons generate their destructive power through the fission (splitting) of atomic nuclei. The only three materials known to be fissionable in weapons are two isotopes of uranium (U), U-235 and U-238, and one isotope of plutonium (Pu), Pu-239. Isotopes are different kinds of atoms of the same element. Each kind has a different mass (total amount of matter). See Isotope.

Nuclear fission occurs when a neutron—a subatomic particle with no electric charge—strikes the nucleus of a uranium or plutonium atom. Splitting the nucleus transforms a small amount of its mass into a large amount of energy. In addition, two or three additional neutrons are released. These neutrons may then split other nuclei. If this process continues, a self-sustaining chain reaction begins in which many neutrons split rapidly, and their combined energies produce a fission explosion.

Generating a self-sustaining chain reaction requires a minimum amount of fissionable material known as the critical mass. A mass too small to support a self-sustaining chain reaction is called a subcritical mass.

A fission weapon uses one of two methods to create...
Nuclear weapons include missiles and artillery shells. The top photograph at the left shows the launching of two long-range nuclear missiles. Such missiles carry extremely powerful thermonuclear devices. The explosion of such a device creates a huge mushroom-shaped cloud like the one shown at the right. A self-propelled howitzer, bottom left, can fire nuclear artillery shells.

Critical mass: (1) the gun-type method or (2) the implosion method. In the gun-type method, two subcritical pieces of material are placed in a device similar to the barrel of a gun. One piece rests at one end of the barrel. The other is some distance from the first piece, with a powerful conventional explosive behind it. The barrel is sealed at both ends. When the weapon's fuse is triggered, the conventional explosive propels the second subcritical mass at high speed into the first. The resulting combined mass immediately becomes supercritical greater than critical), causing a rapid, self-sustaining chain reaction, and thus a nuclear explosion. The United States used a gun-type fission bomb at Hiroshima.

In the implosion method, a subcritical mass is made supercritical by compressing it into a smaller volume. The subcritical mass is in the center of the weapon, surrounded by conventional explosives. When the fuse is triggered, all the conventional explosives go off at the same time. The explosions compress the mass into a high-density supercritical mass. A self-sustaining chain reaction occurs, causing the explosion. The United States used an implosion-type fission bomb at Nagasaki.

Thermonuclear weapons get their power from the fusion (combining) of atomic nuclei under intense heat. The nuclei fused in thermonuclear weapons are of the hydrogen isotopes deuterium (H-2) and tritium (H-3). Fusion reactions require temperatures equal to, or greater than, those found in the sun's core—about 7,000,000 °F (15,000,000 °C). The only practical way to achieve such temperatures is by a fission explosion. Thus, an implosion-type fission device triggers thermonuclear explosions. When the fission device explodes, it also releases neutrons that bombard a compound inside the weapon. This compound, called lithium-6 deuteride, consists of deuterium and lithium-6 (Li-6), an isotope of the element lithium. When struck by the released neutrons, the Li-6 forms helium and tritium. Then, pairs of tritium nuclei, pairs of deuterium nuclei, and pairs of one tritium nucleus and one deuterium nucleus each fuse to form helium nuclei. A small amount of matter from each deuterium and tritium nucleus converts to a large amount of energy, and a thermonuclear explosion occurs. The yield (explosive power) of a thermonuclear weapon can be increased by blanketing the lithium-6 deuteride with the uranium isotope U-238. The U-238 fissions during the hydrogen explosion.

Effects of nuclear weapons

Nuclear explosive devices have different yields. Some older bombs had yields of about 20 megatons, equivalent to the yield of about 1,540 Hiroshima bombs. A megaton is the amount of energy released by 1 million tons (907,000 metric tons) of TNT. Today, most nuclear devices have yields of less than 1 megaton. Most large thermonuclear weapons are about 8 to 40 times as powerful as the Hiroshima bomb.

The effects of a nuclear explosion can vary greatly, depending on a number of factors. These factors include weather, terrain, the point of explosion in relation to Earth's surface, and the weapon's yield. This section describes the possible effects of a large nuclear weapon. The weapon's explosion would produce four basic effects: (1) a blast wave, (2) thermal radiation, (3) initial nuclear radiation, and (4) residual nuclear radiation.

Blast wave. The explosion begins with the formation of a fireball, a cloud of dust and extremely hot gases un-
Under high pressure, a fraction of a second after the explosion, the gases begin to expand and form a blast wave, also called a shock wave. This wave is like a wall of highly compressed air moving rapidly away from the fireball. The blast wave created by a 1-megaton explosion could travel about 12 miles (19 kilometers) from ground zero in just 50 seconds. Ground zero is the point on the ground directly below the explosion.

The blast wave causes most of the explosion's damage. As the wave moves forward, it creates overpressure, atmospheric pressure above the normal level. A 1-megaton explosion can produce enough overpressure to destroy most buildings within 1 mile (1.6 kilometers) of ground zero. This overpressure can also cause moderate to severe damage within 6 miles (9.6 kilometers) of ground zero. Strong winds accompany the blast wave. These winds may reach speeds of 400 miles (640 kilometers) per hour at 2 miles (3.2 kilometers) from ground zero. The blast wave and wind probably would kill the majority of people within 3 miles (4.8 kilometers) of ground zero and some people between 3 and 6 miles (4.8 and 9.6 kilometers) from ground zero. Many other people within 6 miles of ground zero would be injured.

Thermal radiation consists of ultraviolet, visible, and infrared radiation given off by the fireball. Particles in the air rapidly absorb the ultraviolet radiation, and so it does little harm. However, the visible and infrared radiation can cause eye injuries as well as skin burns called flash burns. Flash burns caused from 20 to 30 percent of the deaths at Hiroshima and Nagasaki.

Thermal radiation also can ignite flammable materials, such as newspapers and dry leaves, causing large fires. Some scientists theorize that, in a nuclear war, the smoke from such fires would absorb enough sunlight to lower the temperature for several months or years. These scientists speculate that the lowered temperatures would result in widespread crop failure and famine. The possible effect of nuclear war is called nuclear winter. However, the effects of thermal radiation can vary considerably, depending on a number of condi-

---

**Hiroshima, Japan**, was largely destroyed by a gun-type fission bomb called the Little Boy bomb, top, on Aug. 6, 1945. The bomb was dropped from a B-29 bomber. When the bomb reached 1,850 feet (564 meters), a radar echo set off an explosive inside. This explosive drove a wedge of U-235 into a larger piece of U-235, setting off the nuclear blast. This photograph shows Hiroshima after the explosion.

**Nagasaki, Japan**, was struck by an implosion-type fission bomb called the Fat Man bomb, top, on Aug. 9, 1945. In this bomb, an explosive crushed a hollow sphere of plutonium into a core made up of the chemical elements beryllium and polonium. This core then released neutrons, which triggered a fission chain reaction in the plutonium. This photograph shows Nagasaki after the nuclear blast.
tions at the time of the explosion. In a light atmospheric haze, for example, the effects could be only one-hundredth as strong as they would be in clear air.

A person can be shielded from the direct effects of thermal radiation by solid, nontransparent objects, such as walls, buildings, trees, and rocks. In addition, light-colored clothing reflects heat, and so can help protect a person from flash burns. However, thermal radiation from a 1-megaton explosion can produce second-degree burns (blistering) of exposed human skin up to 11 miles (18 kilometers) from ground zero. The thermal radiation would last only about 10 seconds. Thus it would char, but not completely burn, heavy fabrics and thick pieces of wood or plastic.

Initial nuclear radiation occurs within the first minute beginning at the instant of the explosion. It consists of neutrons and gamma rays, a form of radiation similar to X rays. The fireball emits neutrons and some of the gamma rays almost instantaneously. The rest of the gamma rays are given off by a huge mushroom-shaped cloud of radioactive material formed by the explosion. Nuclear radiation can destroy living cells and prevent normal cell replacement. Large doses of radiation can cause death. For more information about how radiation effects the body, see Radiation (Effects of radiation) and Radiation sickness.

The amount of harm to a person from initial nuclear radiation depends in part on the person’s location in relation to ground zero. Initial radiation decreases rapidly in strength as it moves away from ground zero. In all nuclear explosions, for example, initial radiation at about \( \frac{1}{2} \) mile (0.8 kilometers) from ground zero is only about one-tenth to one-hundredth as strong as radiation at ground zero.

Residual nuclear radiation is given off later than the minute after the explosion. Residual radiation created by fission consists of gamma rays and beta particles (electrons). Residual radiation produced by fusion is made up primarily of neutrons. It strikes particles of rock, soil, water, and other materials that make up the mushroom-shaped cloud. As a result, these particles become radioactive. They fall back to earth and are known as fallout. The closer an explosion occurs to Earth’s surface, the more fallout it produces.

Early fallout reaches the ground within 24 hours of the explosion. Its heavier particles are highly radioactive, and most fall downwind from ground zero. Early fallout lls or severely injures living things.

Delayed fallout reaches the ground from 24 hours to several months after the explosion. It consists of tiny, ten invisible, particles that may fall in small amounts over large areas. Such fallout causes long-term radiation damage to living things. See Fallout.

Types of nuclear weapons

Nuclear weapons can be divided into two main types, depending on the military role for which they are designed. These types are (1) strategic nuclear weapons and (2) theater nuclear weapons.

Strategic nuclear weapons are designed primarily to launch an attack from great distances on targets in an adversary’s homeland. These weapons include bombs and missiles delivered by long-range bomber aircraft. They include missiles that can deliver explosive devices to targets up to 6,500 miles (10,500 kilometers) from the launch site. Some of these missiles are based on land. Others are based underwater on submarines. Strategic nuclear missiles include intercontinental ballistic missiles (ICBMs), submarine-launched ballistic missiles (SLBMs), and cruise missiles. See Guided missile (Ballistic missiles; Nonballistic missiles).

Some strategic nuclear missiles have several nuclear warheads, each of which carries explosive material to a separate target. These warheads are called Multiple Independently Targetable Reentry Vehicles (MIRVs).

Strategic nuclear weapons can destroy or disable a military opponent’s strategic nuclear weapons. They also can disrupt an enemy’s economy or social organization.

Theater nuclear weapons are designed for use within a military theater; a large area in which military operations may be conducted. Smaller or shorter-range theater nuclear weapons are also called tactical nuclear weapons. Theater nuclear weapons can be used to attack conventional forces during a battle or military campaign, or to attack the enemy’s theater nuclear weapons. Theater nuclear weapons include medium-range ballistic and cruise missiles, and short-range guided missiles and unguided rockets. They also include artillery shells, nuclear mines, and torpedoes.

Nuclear weapons in military planning

For nearly 50 years following World War II, nuclear weapons dominated the military planning of the United States. Currently, the United States has an arsenal of more than 10,000 nuclear weapons in its inventory, including both nuclear warheads and delivery systems. The United States and Russia have over 1,000 strategic nuclear warheads, and both countries are committed to reducing their nuclear arsenals.

The nuclear arms race during the Cold War resulted in a massive buildup of nuclear weapons and delivery systems. This race created a sense of mutual destruction, which led to a strategy of nuclear deterrence. Deterrence means that each side is assured that the other side would suffer unacceptable damage if it were to use nuclear weapons.

Today, the United States is focused on reducing its nuclear arsenal and ensuring that it has a balanced mix of nuclear and nonnuclear capabilities. The United States is investing in new technologies, such as advanced missile defense systems, to help protect against the threat of nuclear attack. The United States is also working with other countries to reduce the global threat of nuclear weapons.

In conclusion, nuclear weapons have had a significant impact on global politics and military strategy. The United States is committed to reducing its nuclear arsenal and ensuring that it has a balanced mix of nuclear and nonnuclear capabilities. The United States is working with other countries to reduce the global threat of nuclear weapons.

---

Thermonuclear warhead

A possible design of a thermonuclear warhead is shown here. The fission device explodes and produces hydrogen isotopes from the lithium deuteride. The isotopes then fuse, creating a thermonuclear explosion that fissions the U-238 and increases the warhead’s power.

States and the Soviet Union, the world’s leading military powers. Their national arsenals of nuclear weapons increased and decreased as tensions between the countries grew and declined. But nuclear weapons have changed their military role over time, and several regional military powers have acquired such weapons.

**The United States.** In the mid-1930’s, some U.S. military planners began to see airpower as the best means of ending a war quickly. They favored using bombers to strike a quick, crushing blow against an aggressor’s homeland. During World War II, this airpower theory led the United States to drop many conventional bombs on Germany and Japan. However, the war lasted several years despite the bombing. Germany surrendered only after Allied ground forces defeated its army. Japan surrendered soon after nuclear bombs hit Hiroshima and Nagasaki.

Supporters of the airpower theory thought that Japan’s surrender after the use of nuclear bombs confirmed their theory. As a result—and because it is far cheaper to build and maintain nuclear weapons than conventional forces—nuclear weapons became central to U.S. strategic military power during the Cold War.

In the mid-1950’s, the United States adopted the policy of **massive retaliation.** This policy stated that if Soviet forces struck any area vital to the United States or its allies, the United States might respond with a major nuclear strike against the Soviet Union.

In the early 1960’s, the policy of massive retaliation was replaced by that of **flexible response.** Under this policy, the U.S. response to enemy aggression would match the nature of the aggressor’s attack. The United States could use any type of weapon to stop the attack, including conventional forces or nuclear weapons.

In the 1980’s, advances in conventional military tactical practices and in military technologies made possible a sweeping transformation of strategy that military planners called the **revolution in military affairs** (RMA). The RMA included a shift from large forces and massive bombing to precision strikes, using “smart” munitions, delivered by smaller, more agile forces. The United States and other nations with modern technology turned increasingly to new and highly advanced conventional weapons instead of nuclear arms. In 1990, the United States announced that it would use a nuclear weapon only as a last resort. Elements of the RMA proved effective against Iraq in the Persian Gulf War of 1991 and in operations in Yugoslavia in 1999 and in Afghanistan in 2002.

**The Soviet Union.** Beginning in the 1930’s, Soviet planners based their military strategy on the **deep battle theory.** They stressed the use of all available weapons in a fast, overwhelming, and, when possible, surprise offensive. Most experts believed such a strike could include nuclear weapons. The Soviet nuclear arsenal consisted mainly of large land-based missiles. The Soviet focus on surprise offensives especially concerned U.S. planners, because a portion of the Soviet nuclear arsenal might have crippled U.S. missile and bomber forces in a **first strike** (initial nuclear attack).

**Control of nuclear weapons**

Because of the great dangers associated with nuclear weapons, many nations have made attempts to control them. The chief approaches to control have been strategies of deterrence and the placing of limits on the testing, numbers, and proliferation of nuclear weapons.

**Deterrence** refers to preventing the countries that have nuclear weapons from using them. Theories of deterrence may be offense-based or defense-based.

Offense-based deterrence theory holds that the possession of a strong nuclear force by opposing nations best prevents nuclear war. Forces must be so large that, even if attacked first, a defender would retain enough weapons to devastate an aggressor. The theory relies on a potential aggressor’s belief that, no matter how powerfully it attacks, it will suffer a counterattack and unacceptable destruction in return. The theory was widely called the doctrine of **mutually assured destruction** (MAD).

Offense-based deterrence depends on nations being unable to defeat or seriously limit a nuclear strike against them. In 1972, the Strategic Arms Limitation Talks (SALT) between the United States and the Soviet Union concluded with a treaty called SALT I, which included strict limits on each country’s defenses against nuclear missiles. Such defenses use **antiballistic missiles** (ABMs) to destroy incoming nuclear missiles before they reach their targets. SALT II ABM Treaty limited each nation to one missile **site** (permanent location) with only 100 missiles.

Defense-based deterrence theory agrees with offense-based theory that a major nuclear power will not attack unless it is sure it can destroy a victim’s ability to launch a nuclear counterattack. However, defense-based theory also holds that only an effective defense against a powerful first strike will reliably protect a defender’s ability to counterattack.

In cases of threat from a limited nuclear attack, many military experts hold that an effective defense will either deter the attack or, at least, limit major destruction. However, no country today has an effective defense. From 1983 to 1993, the United States carried out research on a program known as the Strategic Defense Initiative (SDI), a space-based system of defense against missiles. SDI was originally intended as a complete protection against nuclear attack, but in later stages, it aimed to protect against more limited nuclear attacks. See Strategic Defense Initiative.

By 2000, many people in the United States supported the idea of building a limited defense against attacks by small numbers of nuclear weapons that might be launched by terrorist groups or by what some leaders call “rogue nations”—small or medium-sized nations that ignore international law and support terrorism. Others objected that developing such a national missile defense system would violate the 1972 ABM Treaty, a major part of SALT I. Following terror strikes against the United States on Sept. 11, 2001, the United States withdrew from the ABM Treaty in June 2002 and increased spending on a defensive system.

**Limiting testing.** Nations have sought to limit the testing of nuclear weapons to protect people and the environment from nuclear radiation and to slow the development of nuclear weapons. In 1963, the Soviet Union, the United Kingdom, and the United States negotiated the first—and still chief—test limitation treaty, the Limited Test Ban Treaty. They agreed not to test nuclear...
wepons in the atmosphere, in outer space, or underwater. Only underground testing was not banned.

In 1974, the United States and the Soviet Union agreed not to test explosive devices with yields above 150 kilotons. A kiloton is the amount of energy released by 1,000 tons (907 metric tons) of TNT. This agreement, contained in the Threshold Test Ban Treaty, took effect in 1990, the year it was ratified by both countries. But both nations had followed the treaty's guidelines long before ratification.

In 1996, the United Nations approved the Comprehensive Nuclear Test Ban Treaty, which would end all testing of nuclear weapons. To go into effect, the treaty must be ratified by all countries that have nuclear reactors (devices for producing nuclear energy). About three-fourths of the countries with reactors have ratified the treaty.

Limiting numbers. Attempts to limit the number of U.S. and Soviet nuclear weapons began about 1970. The first efforts, under the SALT approach, imposed limits at then-existing levels for some weapons and at higher levels for others. Both nations ratified the 1972 SALT I treaty. However, the U.S. Senate refused to ratify the 1979 SALT II treaty after Soviet forces invaded Afghanistan. See Strategic Arms Limitation Talks.

In 1982, U.S. President Ronald Reagan began the Strategic Arms Reduction Talks (START). These talks aimed for the first time at deep reductions in offensive strategic weapons. The START approach took root in 1987, when Reagan and Soviet President Mikhail S. Gorbachev signed the Intermediate-Range Nuclear Forces (INF) Treaty. This treaty called for the elimination of all U.S. and Soviet ground-launched nuclear missiles with ranges of 500 to 5,500 kilometers (310 to 3,420 miles). It took effect in 1988.

Efforts to limit nuclear weapons quickened following the INF Treaty. From 1989 to 1992, major political reforms in the Soviet Union and Eastern Europe, including the fall of most Communist governments, led to reduced tensions and general arms reductions. In 1990, the United States, the Soviet Union, and 20 other nations signed the Treaty on Conventional Armed Forces in Europe (CFE). The CFE Treaty, which took effect in 1992, called for the destruction of large numbers of tanks and other conventional weapons in Europe.

With international tensions reduced, and the INF and CFE treaties achieved, U.S. President George H. W. Bush and Soviet President Gorbachev in July 1991 signed the first treaty to significantly reduce existing numbers of strategic nuclear weapons. The Strategic Arms Reduction Treaty, now known as START I, aimed to reduce U.S. and Soviet long-range nuclear missiles and bombers from 23,500 to 15,400. START I officially took effect in 1994. Soon after its signing, in September 1991, the United States announced that it would destroy all of its ground-based tactical nuclear weapons and many of those carried by ships and aircraft. The following month, the Soviet Union announced similar steps.

The Soviet Union broke up in December 1991, seemingly ending the immediate threat of large-scale nuclear war. The United States and the four states that controlled portions of the former Soviet Union's nuclear arsenal—Russia, Ukraine, Belarus, and Kazakhstan—recommitted themselves to START I in May 1992.

In 1993, U.S. President George H. W. Bush and Russian President Boris Yeltsin signed START II, a new arms-reduction treaty that aimed to cut the total number of strategic nuclear weapons in the United States and the former Soviet republics to between 6,000 and 7,000. START II also called for the elimination of land-based MIRV's. By late 1996, Ukraine, Belarus, and Kazakhstan had turned over all their nuclear weapons to Russia. In May 2002, U.S. President George W. Bush and Russian President Vladimir Putin signed an agreement to further cut their strategic nuclear arsenals to between 1,700 and 2,200 warheads for each country by 2012.

Limiting proliferation involves preventing the spread of nuclear weapons to nations that do not have them. In 1968, the United Nations approved the Treaty on the Non-Proliferation of Nuclear Weapons. The treaty has since been ratified by nearly all countries.

History

The beginnings. Scientists gained an understanding of the basic structure of the atom during the late 1800's and early 1900's. In 1938, researchers discovered that splitting the nucleus of a uranium atom released much energy. See Atom (Development of the atomic theory); Nuclear energy (The development of nuclear energy).

World War II. By early 1939, only months before the start of World War II, physicists in the United States had become aware of the potential military applications of nuclear energy. They became concerned that Nazi Germany might develop a nuclear weapon.

In August 1939, the German-born physicist Albert Einstein helped alert U.S. President Franklin D. Roosevelt to the potential military applications of nuclear fission. World War II began on Sept. 1, 1939. The United States entered the war in December 1941. In 1942, the U.S. government set up the Manhattan Project to design and build a fission bomb.

On July 16, 1945, Manhattan Project scientists led by the American physicist J. Robert Oppenheimer exploded the first experimental nuclear device. It was a 22-kiloton implosion-type fission device. The test, at the Trinity test site near Alamogordo, New Mexico, convinced U.S. leaders that fission weapons could be built.

The first nuclear weapon used against Japan was a gun-type fission bomb. Its yield was about 13 kilotons. The bomb was dropped from an American B-29 aircraft on the city of Hiroshima on Aug. 6, 1945. Three days later, another B-29 dropped a 22-kiloton implosion-type fission bomb on Nagasaki, Japan. These bombs largely destroyed both cities, but the number of deaths differed greatly. The smaller bomb killed from 70,000 to 100,000 people in Hiroshima, which has a flat terrain. The larger bomb killed about 40,000 in Nagasaki, which has hilly terrain. Other people in both cities died later of injuries and radiation. On Aug. 14, 1945, Japan agreed to surrender, ending World War II.

The Cold War. By the late 1940's, tension between the Soviet Union and the United States led to a bitter struggle known as the Cold War. During the Cold War, many nuclear weapons were developed. See Cold War.

In 1949, the Soviet Union tested its first fission device in the midst of rising tension. In 1952, during the Korean War, the United States exploded the first experimental thermonuclear device. The Soviet Union set off its first
weapons-grade thermonuclear device in 1955. In the mid-1950's, the Soviets built the first submarines equipped with nuclear missiles. In 1957, they test-launched the first land-based intercontinental ballistic missile (ICBM). The first U.S. ICBM became operational in 1959. Also in 1959, the United States commissioned its first submarine equipped with SLBM's. The first MIRV's were acquired in the 1970's, first by the United States and then by the Soviet Union.

After the Cold War. Political developments in Eastern Europe and the Soviet Union from 1989 to 1992 ended the Cold War. Concern in Europe shifted from fear of massive conventional attack to ensuring political—and military—stability. World leaders began to focus on reducing nuclear arsenals and properly controlling them. Following the September 11 terrorist attacks in New York City and Washington, D.C., many nations began to perceive a new threat from terrorists who might gain access to nuclear arms, possibly with support from hostile countries.

Questions

When was the first thermonuclear device exploded?

How does radiation affect human cells?

What kind of bomb was dropped on Hiroshima? Nagasaki?

Why did nuclear weapons become the chief source of U.S. strategic military power after World War II?

What is a subcritical mass?

Why have nations sought to limit nuclear weapons testing?

How are the extremely high temperatures required by fusion reactions achieved?

What is ground zero?

In what ways does an enhanced radiation weapon differ from a typical thermonuclear weapon?

What is a megaton?

Additional resources

**Nuclear winter** refers to the deadly worldwide environmental effects that could result from a major nuclear war. Such a war could bring on nuclear winter by drastically changing the earth's atmosphere and climate.

Nuclear winter could begin to develop from city fires created by the extreme heat of nuclear explosions. Large amounts of smoke from these fires could spread and cover at least half of the earth's surface. The smoke could prevent most sunlight from reaching the ground. Temperatures could drop substantially, and rainfall could be reduced. These conditions might last for several months or years. With greatly reduced sunlight, less rain, and lower temperatures, farming could stop, and worldwide famine could result. Nuclear winter also could reduce the earth's ozone layer, which protects people and other forms of life from the sun's dangerous ultraviolet light.

Scientists estimate that the nuclear explosions in a major nuclear war could kill 500 million people. But 4 billion more people could starve to death in the next year because of nuclear winter. Thus, nuclear winter could endanger every country.

**Nuclear acid.** See DNA; RNA.

**Nucleus.** See Ameba; Atom; Cell; Comet; Nuclear energy; Radioactivity.

**Nuer, NOO uhr,** are a cattle-keeping people of northeast Africa. About 700,000 Nuer live in the grasslands and swamps along the Nile River in southern Sudan and western Ethiopia. They speak a language called Nuer, which belongs to the Nilotic-Saharan family of African languages that also includes Dinka and Masai.

The Nuer played a central role in the social and religious life of the Nuer. A Nuer bridegroom gives a large gift of cattle to his bride's family. The Nuer sacrifice cattle to their supreme god and to lesser spirits. Milk and milk products make up much of their diet, but the Nuer do not eat their cattle for meat.

The Nuer move to higher ground during the rainy season, from May to December, when the Nile River floods. There they raise peanuts, a grain called *millet*, and other vegetable crops. The Nuer build houses of sun-dried mud and make thatched roofs for them. The Nuer are divided into clans whose members have a common ancestor. Until the 1900's, the Nuer were not organized under the control of leaders. A religious expert called the *kuwaarmoon* or *leopard-skin chief* helped settle disputes and presided over religious ceremonies.

The United Kingdom and Egypt made Sudan a protectorate in 1899 and brought many changes to the Nuer, including the creation of tribal chiefs and administrators.

Arabic-speaking Muslims from northern Sudan have controlled Sudan's government since the nation gained...
independence in 1956. In the 1980's, the Nuer joined other black African groups, including the Dinka, to form an opposition group called the Sudan People's Liberation Army (SPLA). Southern Sudan suffered brutal fighting and numerous famines as the SPLA battled for independence from the Muslim north. In the 1990's, the SPLA split into several ethnic divisions. The Nuer continued to fight the Sudanese government, which opposes granting independence to the south.

**Nuevo Laredo**, **nway voh lah RAY doh** or **noo AH voh loo RAY doh**, is a city on the eastern part of Mexico's border with the United States. For location, see Mexico (political map). Three road bridges across the Rio Grande link the city with Laredo, Texas, which is located just north of the border.

Nuevo Laredo is a major point of entry into Mexico. It lies at the northern end of one of the stretches of the Pan American Highway, a major road to Mexico City.

**Nuevo Laredo** lies on Mexico's border with the United States. His photograph shows a main business district of the city.

Each year, millions of American tourists visit the city. They shop in handicraft stores; attend bullfights, dog races, and horse races; and fish in a large lake nearby. The city of Laredo was founded in 1755. It then included what are now Laredo and Nuevo Laredo. Laredo and Nuevo Laredo became separate cities in 1848, when the treaty of Guadalupe Hidalgo established the boundary between Mexico and Texas. **Nuevo** in the name Nuevo Laredo means **new**.

**nullification**, **nul uh fuh KAY shuhn**, is the action of setting aside a law by declaring it **null and void**. The cited States Constitution does not provide any way for law of Congress to be declared unconstitutional after has been signed by the president. Some delegates to the Constitutional Convention believed that the courts could naturally assume this authority. But only in 1803, in the case of **Marbury v. Madison**, did the Supreme Court of the United States flatly assert the right of the courts to pass on the constitutionality of an act of Congress.

The theory that the states, rather than any branch of the federal government, should have the right to **nullify** (declare unconstitutional) a law of Congress, developed slowly. The Kentucky and Virginia Resolutions of 1798 protested the Alien and Sedition Acts passed by Congress. Many people believed that these acts violated the First Amendment. They wanted all the states to declare the acts unconstitutional. But no other state would join in the action. In 1799, the Kentucky legislature stated its belief in the legality of nullification, but merely entered a protest against the Alien and Sedition Acts.

Nullification was next seriously proposed in 1828, when John C. Calhoun prepared a document known as the South Carolina Exposition. Rising industrial interests of the Northeast had persuaded Congress to include in the tariff law of 1828 (the "tariff of abominations") protective duties that the cotton-growing South disliked. Sentiment against the tariff was strongest in South Carolina. There was even talk of secession.

Calhoun's motive in recommending nullification was to provide an alternative to secession. He argued that the federal government had no right to judge the constitutionality of its acts. He also insisted that the states had given certain powers to Congress, and were alone competent to say whether or not Congress had exceeded its powers. Calhoun's reasoning was set forth by Senator Robert Y. Hayne in his famous debate with Senator Daniel Webster in 1830. Webster said nullification would break up the Union, and closed with the words: "Liberty and Union, now and forever, one and inseparable!"

In 1832, Congress again passed a protective tariff act. South Carolina passed an ordinance which declared the tariff laws of 1828 and 1832 null and void in that state. It threatened to leave the Union if the federal government tried to enforce the tariff laws anywhere in South Carolina. President Andrew Jackson warned the people that the laws would be enforced. He also took measures to make sure that the tariff would be collected at the important port of Charleston. After Congress passed a law called a **force bill** to uphold Jackson's position, it became clear that resistance was unwise. Besides, the Compromise Tariff of 1833, engineered through Congress by Henry Clay, greatly reduced the tariff duties.

Nullification was only one manifestation of the doctrine of states' rights, which, insofar as it meant the supremacy of the states over the nation, was ended by the American Civil War.

Robert M. Weir

See also Calhoun, John C.; Force bill; Hayne, Robert Y.; States' rights; Webster, Daniel.

**Numbat** is an Australian marsupial with distinctive striped coloring. It grows about 10 inches (25 centimeters) long and has a bushy tail. The numbat is rusty-red above and white below. The hind third of the back is crossed by about six white stripes. A black stripe runs through the eye from snout to ear. Unlike most female marsupials, female numbats do not have a pouch for carrying their young. Instead, young numbats cling to their mother's body for the first few months of life.

Numbats feed during the day mainly on termites, which they catch by scratching open the insect's underground tunnels. The termites are caught on the numbat's long, sticky, cylindrical tongue. Numbats live in scrub woodland. They shelter at night in hollow logs. The numbat was once common over much of the south-
ern half of Australia but is now found only in the southwestern corner.

Scientific classification. The numbat makes up the numbat family, Myrmecobiidae. It is Myrmecobius fasciatus.

Number, in grammar, is a feature of language that indicates how many persons or objects are referred to. In English, the form of a noun shows whether the reference is to one person, place, object, or idea, or to more than one. The form that indicates only one is called the singular. The form that indicates more than one is called the plural. Some other languages have a singular form, indicating one; a dual form, indicating two; and a plural form, indicating more than two. The plurals of English nouns are formed in regular and irregular ways.

Regular plurals are formed by adding -s or -es to the singular forms of the noun, as in cap, caps and church, churches. Compound nouns form plurals with the addition of -s or -es, but the placement varies. For example, the plural of brother-in-law is brothers-in-law. But the plural of grown-up is grown-ups. And in manservant, both parts take the plural form—menservants.

Irregular plurals are not formed according to any established rule, as are regular plurals. The plurals of some nouns of Old English origin are formed by a vowel change, as in man, men and tooth, teeth. A small number of nouns still have the Old English plural ending -en—for example, ox, oxen and child, children.

About a dozen nouns that end in -f for -fe are changed to -ves in the plural, among them half, halves and wife, wives. But not all nouns that end in -f or -fe follow this pattern. For example, roof and chief form regular plurals—roofs and chiefs.

Some nouns, such as barracks, deer, and sheep, have the same form in both the singular and the plural. A few expressions use a singular form even though a plural is actually called for. These include two-inch nail, six-foot man, and two-gallon bucket.

Some nouns, including cowardice and brilliance, have no plural. They differ from such nouns as deer and sheep because two sheep is correct, but two cowardices is not. The plural of cowardice would usually be expressed by saying something like There are different kinds of cowardice.

Foreign plurals. Words coming into English from foreign languages sometimes keep their foreign plurals. Such foreign plurals are mostly from Greek and Latin words. Some of these are phenomenon, phenomena; criterion, criteria; alumnus, alumn; alumna, alumnae; fungus, fungi; and thesis, theses. There is a strong tendency for such words to go into the regular English plural group. For example, at an earlier period the plural of stadium was the foreign form stadia. Now, however, stadia is the plural form commonly used.

The spelling of plurals in English has many irregularities that are not reflected in speech. Singular nouns that end in -y, following a consonant, are changed to -ies in the plural—for example, lady, ladies; flurry, flurries; and candy, candies. For those ending in -y, preceded by a vowel, -s is added, as in alley, alleys and day, days. Some nouns that end in -o have -s added: silos and pianos. Others, for no special reason, have -es added: tomatoes and heroes. Several even have optional forms, such as zeroes or zeros and ghettos or ghettos.

English pronouns also have plurals, but the relationship is not so consistent as in nouns. We can be called the plural of I, and they the plural of he, she, and it. These is the plural of this, and those the plural of that.

English verbs reflect number by agreeing with the subject. For example, the verb play occurs with a plural subject in the sentence The boys play baseball every day. The verb appears with a singular subject in The boy plays baseball every day. Patricia A. Moody.

See also Declension; Inflection; Noun (Number and case); Pronoun; Verb.

Number and numeral. A number is an idea that is used to refer to amounts of things. People use number
words, number gestures, and number symbols. Number words are said out loud. Number gestures are made with some part of the body, usually the hands. Number symbols are marked or written down. A number symbol is called a numeral. When we read a numeral out loud, we say the number word for that numeral. When we want to write a number, we can write the numeral or the word. For example, we say the word five and write the numeral 5 or the word five. The number is the idea we think of when we see the numeral or when we see or hear the word.

There are several kinds of numbers. Cardinal numbers tell how many things there are, as in "There are five people in my family." Ordinal numbers tell the position of something in an ordered set. For example, "I am sixth in line for lunch." Denominate numbers tell how many units of something there are, as in "I weigh 62 pounds." Denominate numbers are also called measure numbers. See Denominate number. Karen Connors Fouson

**Number theory** is the branch of mathematics concerned with the properties of the natural numbers 1, 2, 3, 4, and so on. Number theory also deals with a type of natural numbers called prime numbers. A prime number, such as 2, 3, 4, 5, or 71, is a natural number that can be divided without a remainder only by itself and 1. About 300 B.C., the Greek mathematician Euclid discussed prime numbers in his book *Elements*. He proved that there are infinitely many prime numbers. Euclid's *Elements* also stated a famous property of natural numbers called the fundamental theorem of arithmetic. This theorem states that every natural number can be written as a product of prime numbers in exactly one way.

The systematic study of number theory began with the work of the French mathematician Pierre de Fermat in the 1600's. A landmark book in number theory was *Disquisitiones Arithmeticae* (1801), by the German mathematician Carl Friedrich Gauss. It developed a comprehensive theory of natural numbers, including a proof of the fundamental theorem of arithmetic. Thomas Butts

See also Fermat, Pierre de; Gauss, Carl Friedrich.

**Numbers, Book of**, is the fourth book of the Bible. Its title, which comes from ancient Greek and Latin versions of the Bible, reflects parts of the book that describe the census, or numbering, of the Twelve Tribes of Israel. The Hebrew title *In the Wilderness* is perhaps more accurate because the book tells about the Israelites during their traditional 40 years of wandering in the wilderness after their departure from Egypt.

The Book of Numbers begins at Mount Sinai with God ordering the Israelite leader Moses to take a census of the Israelites. The book ends with the Israelites camping on the plains of Moab, an area east of the Jordan River, just before they entered Canaan. The book highlights the personal virtue of Moses as the leader of the difficult and rebellious Israelites. An assortment of religious material is interwoven with the main story, including stories that describe the priestly role of the Levites—one of the Twelve Tribes of Israel. Other passages give procedures for such religious rituals as purification rites and sacrificial offerings to God. Carol L. Meyers

See also Pentateuch.

**Numeral.** See Number and numeral.

**Numeration systems** are ways of counting and of naming numbers. They are also called **numeral systems**. We cannot see or touch numbers, because they are ideas. But we can use symbols to stand for numbers. These symbols are called **numerals**. Here are four numerals that represent the number in a half dozen: 6, six, VI, and $\text{IX}$. The most commonly used numeration system has 10 basic numerals, called **digits**: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9. With these symbols we can represent any number. This system is called a **decimal system** because it is based on 10. The word **decimal** comes from the Latin word for ten. Ten is the base or the scale of the decimal system.

**Kinds of numeration systems**

It is possible to use any whole number greater than one as a base in building a numeration system. The number of digits used is always equal to the base. For example, the decimal system, also called the base 10 system, uses 10 digits. The **binary** system that computers use, also known as the base 2 system, has only 2 digits.

The **decimal system** represents numbers in terms of groups of 10. Suppose you wanted to count the pennies you have saved. Instead of counting them one by one, you could count them in groups of 10. First, you would put them in stacks of 10. Then you would arrange the stacks in groups, putting 10 in each group, as shown.

How many pennies are there? You could count them like this: 2 groups of 10 stacks of 10 = $2 \times (10 \times 10) = 200$; 4 stacks of 10 = $4 \times 10 = 40$; plus 8 single pennies. In all, you have $200 + 40 + 8 = 248$ pennies.

If you had counted the pennies one by one, you would have counted the same total. In decimal counting, you use one-digit numerals to count from 1 to 9. Then you use two-digit numerals to count from 10 to 99. In two-digit numerals, the digit on the left stands for the number of groups of 10. The digit on the right shows the number of ones. For example, the numeral 14 stands for 1 group of 10 plus 4 ones. After 99, you use three-digit numerals. The first digit on the left of these numerals stands for the number of hundreds (groups of 10 tens). Thus, the numeral 248 stands for 2 hundreds + 4 tens + 8, as shown in the illustration.

The value of each digit in a decimal numeral depends on its place in the numeral. Each position has a name that tells its value in terms of 10. In the numeral 248, the 8 is in the ones place; the 4 is in the tens place; and the 2 is in the hundreds place. In numerals with more than three digits, the additional positions are called the thousands place, the ten thousands place, and so on. Each position has a value 10 times greater than the position to its right.
Another way of expressing place value is to use powers of 10. The following table shows the meaning of several powers of 10.

<table>
<thead>
<tr>
<th>Place name</th>
<th>Power of 10</th>
<th>Meaning</th>
<th>Symbol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ones</td>
<td>$10^0$</td>
<td>1</td>
<td>$10^0$</td>
</tr>
<tr>
<td>Tens</td>
<td>$10^1$</td>
<td>$10 \times 1$</td>
<td>$10^1$</td>
</tr>
<tr>
<td>Hundreds</td>
<td>$10^2$</td>
<td>$10 \times 10$</td>
<td>$10^2$</td>
</tr>
<tr>
<td>Thousands</td>
<td>$10^3$</td>
<td>$10 \times 10 \times 10$</td>
<td>$10^3$</td>
</tr>
<tr>
<td>Ten thousands</td>
<td>$10^4$</td>
<td>$10 \times 10 \times 10 \times 10$</td>
<td>$10^4$</td>
</tr>
</tbody>
</table>

The 2 in $10^1$, the 3 in $10^2$, and the 4 in $10^3$ are called exponents. The 10 is called the base. The exponent tells the number of times the base is to be used as a factor. For example, $10^m$ means 10 is used as a factor twice, or $10 \times 10$; and $10^n$ means $10 \times 10 \times 10 \times 10$.

The binary system groups numbers by twos and by powers of two. The word binary comes from a Latin word meaning two at a time. This system uses only two digits: 0 and 1. The numeral $10_m$ (one, zero, base two) stands for two, the base of the system. It means "1 two plus no ones."

In binary counting, single digits are used for none and one. Two-digit numerals are used for $10_m$ and $11_m$ (2 and 3 in decimal numerals). For the next counting number, $100_m$ (4 in decimal numerals), three digits are necessary. After $111_m$ (7 in decimal numerals), four-digit numerals are used until $1111_m$ (15 in decimal numerals) is reached, and so on.

In a binary numeral, every position has a value 2 times the value of the position to its right. For example, in the numeral $1010_m$, the 0 on the right means $0 \times 1$; the 1 at the left of this 0 means $1 \times 2$; the next 0 means $0 \times 2 \times 2$; and the 1 at the far left of the numeral means $1 \times 2 \times 2 \times 2$.

The place value of each position can be expressed in terms of powers of 2. The following table shows the meaning of several powers of 2.

<table>
<thead>
<tr>
<th>Base 2 numeral</th>
<th>Meaning</th>
<th>Decimal numerals</th>
</tr>
</thead>
<tbody>
<tr>
<td>$1_m$</td>
<td>1</td>
<td>$1 = 2^0$</td>
</tr>
<tr>
<td>$10_m$</td>
<td>2</td>
<td>$2 = 2^1$</td>
</tr>
<tr>
<td>$100_m$</td>
<td>4</td>
<td>$4 = 2^2$</td>
</tr>
<tr>
<td>$1000_m$</td>
<td>8</td>
<td>$8 = 2^3$</td>
</tr>
<tr>
<td>$10000_m$</td>
<td>16</td>
<td>$16 = 2^4$</td>
</tr>
</tbody>
</table>

In the numeral $1010_m$, the 0 at the right is in the ones place; the 1 next to it is in the $2^1$ place; the next 0 to the left is in the $2^2$ place; and the 1 at the far left is in the $2^3$ place.

Working with numeration systems

The following examples of addition in the decimal and binary systems may help you understand the use of numerals in arithmetic.

Decimal addition. Such statements as $4 + 5 = 9$ and $3 + 4 = 7$ are called arithmetic (or ith MEHT ihk) facts. We use many such facts in addition.

Decimal addition is a way of combining two or more groups into only one group. The principle of place value is used in adding ones to ones, tens to tens, and so on, as in the following example:

$$
\begin{align*}
24 & \quad 2 \text{ tens } + 4 \text{ ones} \\
+12 & \quad +1 \text{ ten } + 2 \text{ ones} \\
36 & \quad = 3 \text{ tens } + 6 \text{ ones}
\end{align*}
$$

In this example, you use the addition fact $4 + 2 = 6$ and the fact $2 + 1 = 3$ (meaning 2 tens + 1 ten = 3 tens, or 30). Therefore, the sum is 3 tens plus 6, or 36. In some problems, the sum in one or more places is 10 or more. Then you must regroup the sum. Regrouping in addition is sometimes called carrying. The next problem shows how to regroup in decimal addition.

$$
\begin{align*}
48 & \quad \text{four tens } + 8 \text{ ones} \\
+25 & \quad +2 \text{ tens } + 5 \text{ ones} \\
73 & \quad +6 \text{ tens } + 13 \text{ ones} \\
& \quad \text{or, after regrouping,} \\
& \quad 7 \text{ tens } + 3 \text{ ones}
\end{align*}
$$

In this problem, the ones add up to 13, which can be regrouped into 1 ten plus 3 ones. So you write 3 in the ones place and a small 1 in the tens place above the 4. Then you add the tens: $1 + 4 + 2 = 7$ tens, or 70. Therefore, the sum is $70 + 3$, or 73.

Binary addition is based on only these facts:

$$
\begin{align*}
0 + 0 &= 0 \\
0 + 1 &= 1 \\
1 + 0 &= 1 \\
1 + 1 &= 0 + 1 \text{ one}
\end{align*}
$$

Here is the way you use these facts to add $11 + 11$:

$$
\begin{align*}
\text{Binary addition} & \quad \text{Meaning} & \quad \text{Decimal addition} \\
11 & \quad 1 \text{ two } + 1 \text{ one} & \quad 3 \\
+11 & \quad +1 \text{ two } + 1 \text{ one} & \quad +3 \\
110 & \quad 10 \text{ twos } + 10 \text{ ones} & \quad 6 \\
& \quad \text{or, after regrouping,} & \quad \text{or, after regrouping,} \\
& \quad 1 \text{ four } + 1 \text{ two } + 0 \text{ ones} & \quad 1 \text{ four } + 1 \text{ two } + 0 \text{ ones}
\end{align*}
$$

First, you use the addition fact $1 + 1 = 10$ (meaning 1 two) to add the ones. Regroup $10_m$ into 1 two plus no ones. Write 0 in the ones place, and a small 1 above the twos column. Then add the twos: $1 + 1 = 10$; $10 + 1 = 11$. Write 1 in the twos place, and 1 in the fours place. Thus, $11_{\text{two}} + 11_{\text{two}} = 110_{\text{two}}$.

History

How numeration systems began. Ancient people had several ways of recording the few numbers they needed. A shepherd could collect pebbles to represent the number of sheep in a flock. Each pebble meant one sheep. A bag of pebbles stood for the whole flock.

Later, people developed other ways to record the number of possessions they owned. They tied knots in a leather thong or scratched tally marks (\text{\textasciitilde}) on the side of a rock. Then they matched the knots or marks against each item. Next, people began to use words to represent numbers. These words described "how many" and helped people match items mentally. For example, people used the word for "wings" to mean two objects. For five items, they used the word that meant "hand."

Finally, people began to count by arranging the names of numbers in a certain order. To count, they spoke or wrote the word that meant "one," next the word for "two," then the word for "three," and so on. In time, people in many parts of the world developed various counting systems. Some were based on 5, others on 10, and still others on 12 or 60. People still use such measures as 12 inches in a foot and 60 minutes in an hour, taken from these ancient systems.

In most early numeration systems, people formed numerals simply by repeating basic symbols and adding
their values to get the number they wanted. The Egyptians, Greeks, and Romans used numeral systems of this kind. The Maya of Central America and the Hindus of India used systems that followed the principle of place value and used a symbol that meant not any. The Hindu system became the decimal numeral system.

The Egyptian numeral system. About 3000 B.C., the ancient Egyptians used hieroglyphics (picture writing) to write numerals, as shown below.

```
1 / Stroke
10 Arch
100 Coiled Rope
1,000 Lotus Flower
10,000 Finger
100,000 Tadpole
```

This system was based on 10. But it did not include a zero symbol, nor did it use the principle of place value. The Egyptians formed numerals by putting basic symbols together. For example, they wrote the numeral 1,326 like this:

```
\[ \text{1,326} \]
```

The Babylonian numeral system used cuneiform wedge-shaped symbols. An early system of about 2100 B.C. was based on 60. In this system, a numeral contained groups of symbols. One group stood for the number of ones, the next group stood for 60's, the next or (60 × 60)'s, and so on.

The Greek numeral system. About 500 B.C., the Greeks developed a system based on 10. This system used a 27-letter Greek alphabet—the present-day 24-letter alphabet plus 3 letters no longer used. The first 9 letters stood for numbers, from 1 through 9. The next 9 letters stood for tens, from 10 through 90. The last 9 letters were symbols for hundreds, from 100 through 900.

The Roman numeral system uses letters as symbols or numbers. But the early Roman system of about 500 B.C. differed from the system we use today. For example, he ancient Romans wrote 4 as IIII and 9 as VIIII. They used the symbol I for 50 and CI for 100. Today, we usually use IV for 4, IX for 9, L for 50, and M for 1,000. The numerals VI, XV, and LX illustrate the additive principle. When the first of two symbols stands for a larger number than the second, you add the value of the first to the second to get the value of the combination. Thus, he Roman numeral VI represents 6, or 5 + 1; XV represents 15 as 10 + 5; and LX represents 50 + 10 = 60.

The numerals IV and IX illustrate the subtractive principle. When the first of two symbols stands for a smaller number than the second, you subtract the value of the first from that of the second to get the value of the combination. Thus, in the Roman numeral IV, you subtract 1 from 5 to get 4.

The Maya numeral system was based on 20. A dot represented the number one, and a bar represented five. The Maya system was a place-value system, and the Maya used a zero before A.D. 300. With these features, the Maya system could have become the basis of a modern, worldwide numbering system. But by the time the Italian navigator Christopher Columbus made his first voyage to America in A.D. 1492, the decimal system was already established in Europe and in the Arabic and Hindu lands of Asia.

The Hindu-Arabic numeral system. Hindu mathematicians of the 300's and 200's B.C. used a system based on 10. The Hindus had symbols for each number from one to nine. They had a name for each power of 10 and used these names when writing numerals. For example, Hindus wrote "1 sata, 3 dasan, 5" to represent the number we write as 135. They wrote "1 sata, 5" for the number we write as 105.

The Hindus gradually developed a way of eliminating place names. They invented the symbol sunya (meaning empty), which we call zero. With this symbol, they could write "105" instead of "1 sata, 5."

During the 700's, the Arabs learned Hindu arithmetic from writings of the Hindus and the Greeks. Then, in the 800's, a Persian mathematician wrote a book that was translated into Latin about 300 years later. This translation brought the Hindu-Arabic numerals into Europe.

Several centuries passed before the Hindu-Arabic system became widely used. After Europeans learned to print from movable type in the 1400's, they published many mathematics textbooks. Most of the books showed calculations using the Hindu-Arabic system. These books brought the system into widespread use.

The binary system. During the late 1600's, the German mathematician and philosopher Gottfried Wilhelm Leibniz developed the binary numbering system. However, mathematicians found no practical use for the system until the 1940's, when computers were developed.

Nadine L. Verderber

Numerology, the practice of using numbers to analyze character and foresee the future. It is based on the belief that the universe is governed by numerical laws and that each number has special powers and qualities. Most scientists believe that numerology has no scientific basis, but many people throughout the world practice it.

Numerologists believe that a person's name is an important clue to that person's character. Each letter in the name is changed to a number using a system based on ancient Greek and Hebrew alphabets. The numbers are added together and the separate figures in the total are combined to arrive at a number from one to nine. Suppose the numbers derived from a person's name total 75. The 75 is broken into a 7 and a 5, which add up to 12. The 12 is separated into a 1 and a 2, which total 3. This number supposedly reflects the person's character. For example, people with the number one are said to be...
ambitious and forceful. Those with the number two supposedly are quiet and shy.

Another number that numerologists believe reveals character is the birth number, which is determined by adding the figures in a person's birth date. Numerologists also combine the birth number with the figures in any year to find a personal year number. This number predicts what is going to happen to the person in that year. Christopher McIntosh

See also Fortunetelling.

**Numidia, noo MIHD ee uh,** was an area in northern Africa during ancient times. It occupied part of what is now Algeria. Numidia was allied with nearby Carthage when the Second Punic War between Carthage and Rome began in 218 B.C. But Massinissa, a Numidian chieftain, sided with the Roman general Publius Cornelius Scipio. In return, as Scipio's ally, Massinissa was rewarded with territory and became king of all Numidia about 200 B.C. The next year, the Numidians helped Scipio defeat the Carthaginians, who were led by Hannibal, at Zama in northern Africa.

Several times after the war, Massinissa seized land from Carthage. Finally, Carthage fought back, helping bring about the Third Punic War (149-146 B.C.). Rome destroyed Carthage in the war but also halted Numidian expansion. By 112 B.C., Jugurtha, adopted grandson of Massinissa, had seized all of Numidia in defiance of Rome. He was defeated by the Roman general Marius in 106 B.C. In 46 B.C., Numidian King Juba I fought Julius Caesar and was defeated. Caesar annexed Numidia and made most of it a Roman province. Henry C. Boren

**Numismatics.** See Coin collecting.

**Nun** is a woman who belongs to a religious community and dedicates her life to carrying out its goals. Various major religions, including Buddhism, Christianity, and Taoism, have orders of nuns. The Roman Catholic Church has more of these orders than any other Christian denomination.

Most Roman Catholic orders of nuns have different requirements for permanent membership, but they all require years of preparation. When a woman enters an order, she begins a period of spiritual training called a novitiate. During this period, which in many orders lasts several years, she becomes thoroughly acquainted with the obligations of religious life (see Religious life). After her novitiate, the woman takes her first vows, and after several more years, final vows. She promises to give up possession of worldly goods, obey her superiors in the order, and remain unmarried. These promises may be either simple vows or solemn vows. Solemn vows are more binding.

A woman who has taken simple vows is known as a sister. One who has taken solemn vows is properly called a nun. But the term sister is commonly used as a form of address for a nun.

The first convents for women were founded in the Egyptian desert during the early 300's by Saint Pachomius. During the Middle Ages, nuns led strictly cloistered (excluded) lives in such convents. In 1633, Saint Vincent de Paul and Saint Louise de Marillac founded the Daughters of Charity (now often called the Sisters of Charity), an order devoted to charity work outside the convent. The members cared for orphans and the sick and taught children and adults.

The nun's way of life was modernized by Vatican Council II, a worldwide council of the Roman Catholic Church held from 1962 to 1965. Many orders now permit their members to live in small informal groups rather than in a convent. Many nuns no longer must wear the traditional robe and veil. Nuns continue to work in charitable and educational fields. They now also counsel youth in juvenile courts and perform other services as well. Anne E. Carr

**Nunavut, NOO nuh voot,** is a huge region in northeastern Canada that became a separate territory on April 1, 1999. On that date, Nunavut was carved out of the eastern part of Canada's Northwest Territories to provide more self-government for the Inuit, who make up most of the population. Nunavut means Our Land in Inuktitut, an Inuit language. Iqaluit is Nunavut's capital and largest town.

Nunavut is part of a vast subarctic region that has long, cold winters and short, cool summers. The territory is sparsely populated due to its harsh climate, but it has rich mineral deposits. The territory covers about 810,000 square miles (2.1 million square kilometers) and makes up about one-fifth of Canada's land area.

**Land and resources**

**Location and description.** Much of Nunavut lies north of the Arctic Circle. The territory is bordered on the south by the province of Manitoba, on the west by the Northwest Territories, and on the north by the Arctic Ocean. To the east lies Greenland, a province of Denmark, separated from Nunavut by Baffin Bay. Many of the island's north of the Canadian mainland are part of Nunavut. The territory's islands include Baffin, Ellesmere, and Southampton islands, all part of a region known as the Arctic Archipelago. Cape Columbia on Ellesmere Island is Canada's northernmost point.

Nunavut consists mainly of treeless, rocky, rugged terrain. Much of the ground beneath the surface is permafrost (permanently frozen ground). Some permafrost in Nunavut is more than 2,000 feet (600 meters) thick. Only the top 6 to 60 inches (15 to 150 centimeters) of ground thaws in the summer.

Glaciers cover parts of Baffin and Ellesmere islands. The two islands also have rugged mountains and deep fiords (long, narrow bays). Ellesmere Island has a high

**Facts in brief**

**Capital:** Iqaluit.

**Government:** Parliament—members of the Senate, 1; members of the House of Commons, 1. Territorial—members of the territorial Legislative Assembly, 19.

**Area:** 808,185 sq mi (2,093,190 km²)

**Elevation:** Highest—Mount Barbeau in the United States Range, 8,584 ft (2,615 m) above sea level; Lowest—sea level along the coast.

**Population:** 2001 census—26,745; density, 3 persons per 100 mi² (1 per 100 km²).

**Chief products:** Fishing and hunting—char, caribou. Manufacturing—fine arts and crafts. Mining—zinc, gold, lead.
Iqaluit is Nunavut's capital and largest town. It stands on Baffin Island, on the shores of Frobisher Bay. Iqaluit had long been used as a seasonal Inuit fishing camp when Europeans arrived in the area in 1576. The town's name in Inuktitut, an Inuit language, means *place of fish.*

Nunavut is Nunavut's capital and largest town. It stands on Baffin Island, on the shores of Frobisher Bay. Iqaluit had long been used as a seasonal Inuit fishing camp when Europeans arrived in the area in 1576. The town's name in Inuktitut, an Inuit language, means *place of fish.*

Nunavut is home to a variety of wildlife. They include caribou, musk oxen, polar bears, wolves, Arctic foxes, and Arctic hares. Caribou have traditionally been important to the Inuit, providing them with food and clothing. Narwhals and other whales swim the icy waters of the Arctic Ocean. Seals and walruses also live there. Ravens, gyrfalcons, and ptarmigan live in Nunavut the year around. Many other birds, such as eider ducks and snowy owls, migrate to the region in the spring. Snow geese nest on Baffin Island.

Nunavut is rich in mineral resources. The territory has large deposits of copper, diamonds, gold, iron, lead, nickel, silver, uranium, and zinc. However, many of these resources have not been developed because of the region's harsh climate and the difficulty of transportation here. Several companies are also exploring for oil and natural gas in the region.

**Climate.** Nunavut has long, cold winters and short, cool summers. Average winter temperatures range from about -20 °F (-29 °C) in the southern part of Baffin Island to below -35 °F (-37 °C) on Ellesmere Island. Summer temperatures range from above 50 °F (10 °C) in southern Nunavut to about 36 °F (2 °C) in the north.

Nunavut has a dry climate. Nearly all of the territory receives less than 12 inches (300 millimeters) of precipitation a year. The northern part of the territory gets so little precipitation that it is often considered a polar desert.

**People**

Most of the people of Nunavut are Inuit. They live in dozens of small communities located mainly on the coasts. The largest populated place in Nunavut is the capital, Iqaluit. Most homes are provided by the Canadian government. Many residents play sports, and most hunt or fish for pleasure as well as for food. The territory has three official languages: an Inuit language called Inuktitut, English, and French.

Nunavut has a number of major social problems. For example, the territory has high rates of unemployment, suicide, and drug abuse.

**Economy**

Nunavut does not have a fully developed economy. The harsh climate and terrain and the great distances
between places hinder access to the areas that are rich in natural resources. The Inuit are making the transition from subsistence hunting to a wage-earning economy, and the training of skilled workers is an important need.

The Nunavut government is the largest employer in the territory. The government has offices in a number of communities in addition to the capital, in part so that people throughout the territory will have access to government employment opportunities.

Mining contributes more to the economy of Nunavut than any other economic activity. The chief mined products include zinc, gold, and lead. Zinc and lead are mined on Baffin Island and Little Cornwallis Island. A gold mine operates at Contwoyto Lake, near Lupin.

The spectacular scenery of the region—mountains, fiords, and glaciers—and its rich array of wildlife attract many tourists to Nunavut. Inuit organizations and communities have begun to establish hotels, motels, outfitters, and guiding services for visitors. Tourists engage in such activities as hunting, fishing, kayaking, hiking, and exploring. Many people visit the territory’s three national parks, Auyuittuq National Park on eastern Baffin Island, Quttinirpaaq National Park on northern Ellesmere Island, and Sirmilik National Park on Bylot Island and northern Baffin Island.

Traditional arts and crafts have long provided income for some Inuit. Galleries around the world sell Inuit soapstone carvings. Prints from Cape Dorset and Pangnirtung are famous. Inuit weavers produce tapestries at weaving centers in Pangnirtung and Clyde River.

The territory has a small fishing industry and a growing construction industry. Hunting and trapping also provide income for some residents.

Nunavut has few roads and no railroads. Airplanes provide the primary means of transportation between towns in the territory. There is regularly scheduled air service to almost all communities. Many people use snowmobiles to cover short distances. The use of modern-day telecommunications and information technologies, such as the Internet, has helped to overcome the problems of distance. All communities have radio and television, which are transmitted by a satellite relay system. Nearly all communities have telephone service.

**Education**

Nearly all Nunavut communities offer schooling through grade 12. Many Nunavut schools teach Inuktitut in the early grades, and English in the later years. Although the territory’s literacy rate is lower than the national rate, an increasing number of students are attending and completing high school.

Nunavut Arctic College provides further education at its campuses in Iqaluit, Rankin Inlet, and Cambridge Bay. The college also has Community Learning Centres
located in every Nunavut community.

The territorial government is working to improve education in the territory. It hopes to reduce the size of classes, train and hire more Inuit teachers, and develop a curriculum that focuses more on Inuit language, culture, and history.

Government

Nunavut is one of Canada’s three territories. The other two are the Northwest Territories and the Yukon Territory. The people of Nunavut elect one representative to the Canadian House of Commons. Nunavut has one representative in the Canadian Senate.

A premier heads the government with the assistance of an Executive Council (cabinet). Nunavut’s Legislative Assembly elects the premier and the council members from among its own members. The council handles relations with the federal government and the provincial government.

The 19-member Assembly makes the laws for Nunavut. The voters elect members to five-year terms. The Assembly governs by consensus—that is, by general agreement. Nunavut has no political parties.

The territorial government has regional operations in 10 communities outside the capital. Local government is carried out by community groups called hamlet councils.

History

Early history. Ancestors of the Inuit have inhabited the Arctic for thousands of years. The pre-Dorset culture, the first Canadian Arctic culture, spread eastward from Alaska 4,000 years ago. About 3,000 years ago, a new culture called the Dorset spread rapidly across the Arctic. The Dorset people adapted well to life in the harsh Arctic climate. They made snow knives from bones and may have been the first to use the snowhouses called igloos. Their houses were heated by stone lamps fueled with animal fat.

About 1,500 to 1,000 years ago, another new culture, called the Thule (THOO lee), spread across the region, and the Dorset culture disappeared. The Thule people lived in villages in houses with stone floors and walls made from whale ribs or boulders covered with turf. The cornerstone of their culture was whaling. After the decline of whaling, these people hunted caribou and seals. The importance of villages then declined, and smaller groups lived in seasonal camps of tents and snowhouses. By about 1700, the Thule culture had become that of the modern Inuit.

Arrival of the Europeans. The Vikings were probably the first Europeans to visit Nunavut. They may have sighted its Arctic shores about A.D. 1000. About the 1500's, the riches of China encouraged many explorers to look for a Northwest Passage, a sea route through the

Fishing is an important source of food for some people of Nunavut. Most residents also hunt and fish for pleasure. These Inuit are fishing in the waters off the southern tip of Baffin Island.

Symbols of Nunavut

The territorial flag

The territorial coat of arms

The floral emblem

Purple saxifrage

The territorial flag and the coat of arms bear representations of an inukshuk—that is, a traditional Inuit stone monument—and the North Star. On the coat of arms, the Inuit stone lamp next to the inukshuk symbolizes the warmth of family and community. An igloo and crown appear at the top, and a caribou and narwhal support the shield. The motto, written in Inuktitut, means Nunavut Our Strength.
Polar bears are among the rich variety of wildlife found in Nunavut. Other animals that make their homes in the territory include Arctic foxes, Arctic hares, caribou, musk oxen, and wolves.

North American continent to Asia. Martin Frobisher, an English seaman searching for the Northwest Passage, became the first known European to reach Nunavut. He arrived at Baffin Island in 1576.

In 1670, King Charles II of England granted part of Nunavut to the Hudson's Bay Company, a British fur-trading company. The company owned a vast area called Rupert's Land. In 1870, the Dominion of Canada acquired Rupert's Land. At the same time, it obtained from the United Kingdom a region called the North West Territory, which lay north, west, and south of Rupert's Land. The Canadian government organized these two new possessions into the North West Territories, later known as the Northwest Territories. The Canadian government became responsible for administering the Territories.

The Territories lost part of the Manitoba area in 1870, when Manitoba became a province. The Yukon Territory was cut off in 1888, and the provinces of Alberta and Saskatchewan in 1905. In 1912, Manitoba, Ontario, and Quebec acquired certain areas that had belonged to the Territories.

Establishment of Nunavut. For many years, the Inuit of the Northwest Territories had called for their own political unit in the east. They argued that their culture and language were distinct from those of the rest of the Northwest Territories. They also said that the territorial capital, Yellowknife, was too far from their own communities. Yellowknife stands near Great Slave Lake, some 1,500 miles (2,400 kilometers) to the west. In 1982, the people voted to divide the Territories into an eastern and a western territory. The federal government approved the division.

In 1992, the people of the Northwest Territories approved a boundary to divide the two territories. The Inuit territory would be called Nunavut. In 1993, the Canadian Parliament passed the Nunavut Land Claims Agreement Act, which gave the Inuit exclusive ownership of nearly one-fifth of Nunavut's land area, about 135,000 square miles (350,000 square kilometers). Parliament also passed the Nunavut Act, which approved the division of the Northwest Territories and the creation of Nunavut. Nunavut came into being on April 1, 1999.

Nuremberg, NOO ruhm BEHRK (pop. 465,255), is an industrial city in southern Germany. For location, see Germany (political map). The city's name is sometimes spelled Nuremburg. Its German name is Nürnberg. The Pegnitz River divides the central part of Nuremberg in half. A wall completed in the 1400s encircles the city's center. Allied bombing attacks during World War II (1939-1945) destroyed or damaged many of Nuremberg's historic buildings. The city's remaining landmarks include the medieval churches of St. Lawrence and St. Sebaldrus, and the restored house of the famous artist Albrecht Dürer. Nuremberg's many industries include the production of automobiles, beer, bicycles, electrical equipment, office machinery, and toys.

Nuremberg's founding date is unknown, but the city dates from at least the 1000's. During the late Middle Ages, Nuremberg became a prosperous trade and cultural city. Nuremberg was a center of Nazi activities in the 1930's. In 1933, the Nazi-controlled German national assembly approved the anti-Jewish Nuremberg Laws, which were drafted in the city. The laws deprived Jews of citizenship and forbade "Aryan" Germans to marry Jews. Nuremberg was the site of Allied trials of Nazi war criminals (see Nuremberg Trials). Melvin Cron

Nuremberg Trials, NOO ruhm BEHRK, were 13 trials held to judge leaders of Germany for their actions during World War II (1939-1945). The trials took place from 1943 to 1949 in Nuremberg, Germany, where the Nazi Party had staged huge rallies. This party, led by dictator Adolf Hitler, ruled Germany during World War II.

Nazi leaders faced charges of committing aggressive acts and war crimes. These crimes included the murder of about 6 million Jews, known as the Holocaust, and about 5 million other Europeans. The Nuremberg Trials were the first war crimes trials conducted by the victors of a war in modern times. They were organized by the United States, the Soviet Union, the United Kingdom, and France.

The trials. The Nazi leaders were charged with crimes in four major areas—conspiracy to commit crimes against peace, crimes against peace, war crimes, and crimes against humanity. Conspiracy to commit crimes against peace included the planning of a war of aggression. The crimes against peace included carrying out a war of aggression. War crimes covered such acts as the murder of prisoners of war and of civilians, and the excessive destruction of land and cities. Crimes against humanity referred to three main offenses: (1) deporting civilians and using them for slave labor, (2) conducting inhumane medical experiments, and (3) perse-
The Katy Matheson caustic, Iprecher, ilea, Trials vering her ten. He received Ubert Jazi. Nureyev Don his, to Nazis five themselves. Goering, sentenced to, emphasized its Lake, received the United States, the Nazis to, his duty, to obey. F. Hess, Jodl, received death sentences. Ten were hanged on Oct. 16, 1946. Goering committed suicide a few hours before. Bormann's whereabouts were unknown at the time, and he was tried in absentia (while absent). Hess, Doenitz, and five others received prison sentences ranging from 0 years to life in Spandau Prison in Berlin. Twelve more trials took place at Nuremberg from 1946 to 1949. They were conducted by U.S. judges. They evicted 185 defendants, including Nazi Party officials, judges, business executives, and doctors. More than half were sentenced to prison, some received death sentences, and others were found not guilty. Reaction. The Nuremberg Trials aroused considerable controversy. Some observers considered a number of the sentences too harsh. Other critics have pointed out that the victorious nations committed some of the same types of acts for which the Nazis were tried. Also, the Nazis on trial were not allowed to use this argument in their defense. Nevertheless, the Nuremberg Trials have had far-reaching effects. They carefully documented the Holocaust and other Nazi crimes. The trials also rejected the argument that orders from superiors relieve people from responsibility for war crimes. Thus, the Nuremberg Trials emphasized the idea that soldiers and citizens have a moral duty to disobey inhumane orders or laws.

Nureyev, nu RAY yuhr, Rudolf (1938-1993), was one of the great ballet dancers of the 1900's. He became known for his exciting stage personality and his strong, expressive dance technique. Nureyev danced more than 100 roles. In 1962, he began a partnership with the famous English ballerina Dame Margot Fonteyn. Nureyev and Fonteyn performed together in such ballets as Giselle, Swan Lake, and Les Sylphides. As a choreographer (creator of dances), Nureyev created versions of such ballets as Don Quixote and The Nutcracker.
Nureyev was born on March 17, 1938, near Irkutsk, in Russia. He joined the Kirov Ballet in 1958 and soon became its principal dancer. In 1961, Nureyev defected to the West while the Kirov Ballet was performing in Paris.

Rudolf Nureyev became one of the most famous ballet dancers of the 1900's. He won praise for his exciting stage personality and powerful leaps in such ballets as Swan Lake, shown here.

He then danced with ballet and modern dance companies throughout the Western world and appeared in several dance films. He was director of the Paris Opera Ballet from 1983 until 1989.

Nurmi, NUR mee, Paavo, PAH vaw 1897-1973, a Finnish athlete, is considered the greatest distance runner in track and field history. His achievements from 1920 to 1932 made him a national hero of Finland. During that period, Nurmi set 29 world records in distances from 1,500 meters to 20,000 meters. He also won 9 gold medals in the Olympic Games of 1920, 1924, and 1928. At the 1924 Games, he won 5 gold medals, a record in track and field. Over his career, he won 12 Olympic medals in 7 events, including gold medals in 6 events. Both achievements also represent Olympic records in track and field.

Paavo Johannes Nurmi was born on June 11, 1897, in Turku, Finland. He was the first distance runner to scientifically plan his races. For example, he used a stop watch to help run at a desired pace. His Olympic career was cut short just before the 1932 games. The International Amateur Athletic Federation declared that he had accepted too much money for expenses during a European tour, making him a professional athlete and therefore ineligible for the Olympics. Nurse. See Nursing.

Nursery produces and raises plants for transplanting in fields, gardens, orchards, and landscaped areas. Nurseries in the United States raise trees, shrubs, ground covers, and other plants, including flowers and vegetables. Some nurseries produce tropical plants. Most nurseries are commercial operations. Certain agencies of the federal and state governments operate nurseries to reforest public lands. Nurseries produce plants from seeds or cuttings,
or by grafting buds or stems from mature plants onto roots. In addition, certain plants are grown from bulbs or other plant structures. Nursery workers care for the plants by fertilizing and irrigating the soil, and by protecting them from disease, insects, and weeds.

Many nursery plants are container-grown and are sold in their containers. Some field-grown plants are sold balled and burlapped—that is, with their roots and soil wrapped in burlap. Others are sold bare-root with their roots packed in moist material to prevent drying.

There are three kinds of commercial nurseries. Wholesale nurseries sell to other nurseries and handle large quantities of a small variety of plants. Retail nurseries sell directly to the public. They handle relatively small quantities of many kinds of plants. Most retail nurseries operate along busy highways, where they can be reached easily. Some provide planting and maintenance service and also offer planting designs for home gardens and yards. Mail order nurseries distribute catalogs that describe the plants they sell. Many of these nurseries grow only a small portion of their plants. They buy the rest from wholesale nurseries. The major nursery association in the United States is the American Association of Nurserymen. The association is headquartered in Washington, D.C.

Nursery rhyme is a rhythmical poem that amuses or soothes young children. Many nursery rhymes also pass along cultural information and values. These poems are a vital form of folk literature. They appeal to children because of their pleasing rhymes and sounds and compelling rhythms. Youngsters often keep time with the musical rhythm of the words by clapping their hands or rocking back and forth. Nursery rhymes help children appreciate the many sounds and rhythms of a language.

The great variety of stories and characters in the verses stimulates the imagination. Children delight in the humor and surprises in such rhymes as "Mary Had a Little Lamb" and "Hey Diddle Diddle." Other rhymes, including "Three Little Kittens" and "Old Mother Hubbard," introduce children to their first stories. A child's familiarity with nursery rhymes can lead to a lasting appreciation of poetry and prose.

Types

The most popular types of nursery rhymes include (1) lullabies, (2) singing game rhymes, (3) nonsense rhymes, (4) rhyming riddles, (5) counting-out rhymes, (6) tongue twisters, (7) verse stories, and (8) cumulative rhymes.

Lullabies are simple, soothing melodies sung to children to help them fall asleep. "Rock-a-Bye Baby" is probably the best-known lullaby in the English language.

Rock-a-bye, baby, on the tree top,
When the wind blows the cradle will rock;
When the bough breaks the cradle will fall,
Down will come baby, cradle, and all.

Singing game rhymes accompany dances or certain games. For example, "Ring-a-Ring O' Roses" is sung by a group of children who join hands and dance in a circle.

Ring-a-ring o' roses,
A pocket full of posies,
A-tishoo! A-tishoo!
We all fall down.

Nonsense rhymes provide a verbal release from the "sensible" requirements of everyday life. This one has the humor and wit typical of such verses.

I eat my peas with honey,
I've done it all my life.
It makes the peas taste funny,
But it keeps them on the knife.

Rhyming riddles ask children to unravel a mystery or identify a certain object from clues in the verse.

Runs all day and never walks,
Often murmurs, never talks;
It has a bed and never sleeps;
It has a mouth and never eats.

The answer is a river.

Counting-out rhymes provide formulas that help children choose sides for games. The verse "One, Two, Three, Four, Five" is an example.

One, two, three, four, five!
I caught a hare alive;
Six, seven, eight, nine, ten!
I let her go again.

Such rhymes may also help children learn the days of the week, the months of the year, and how to count.

Tongue twisters are difficult to say without making a mistake. The playful challenge of these rhymes comes from reciting them accurately as fast as possible, as in the famous tongue twister "Peter Piper."

Peter Piper picked a peck of pickled peppers;
A peck of pickled peppers Peter Piper picked;
If Peter Piper picked a peck of pickled peppers,
Where's the peck of pickled peppers Peter Piper picked?

Verse stories are short dramatic tales that often are longer than other types of nursery rhymes. "The Queen of Hearts" is a popular verse story.

The Queen of Hearts,
She made some tarts,
All on a summer's day;
The Knaves of Hearts,
He stole those tarts,
And took them clean away;
The King of Hearts,
Called for the tarts,
And beat the knave full sore;
The Knave of Hearts,
Brought back the tarts,
And vowed he'd steal no more.

Cumulative rhymes, in each successive verse, repeat the information presented in the earlier verses. Thus, each verse is longer than the previous one. Here is the first verse of "The House That Jack Built."

This is the house that Jack built.
The second verse has two lines.

This is the malt
That lay in the house that Jack built.
The third verse adds another line to the story.

This is the rat
That ate the malt
That lay in the house that Jack built.
This cumulative rhyme then continues for many more verses.

History

For centuries, nursery rhymes have been passed orally from generation to generation. Every culture has its own nursery rhymes, plus additional ones that have been adopted from other societies. The verses have a wide variety of origins. Some nursery rhymes are fragments of ballads, prayers, proverbs, or tavern songs. Others came from ancient customs or rituals. Still others, such as "Old King Cole" and "Hey Diddle Diddle," may have been based on real people and events. Many nursery rhymes developed a number of versions as they passed orally from generation to generation.

Most nursery rhymes probably originated after 1600, but some rhymes may have been created earlier, such as "Little Tom Tucker." One of the earliest English collections of nursery rhymes, Mother Goose's Melody, was brought out in 1781 by an English publisher. This collection was reprinted in 1786 by an American publisher, Isaiah Thomas.

Many nursery rhymes that date from before 1800 were intended to entertain adults, not children. The rhymes that were written especially for youngsters included alphabet rhymes, lullabies, and verses that were used in games.

The term nursery rhyme first appeared in print in 1824 in Blackwood's Edinburgh Magazine, a Scottish periodical. Before then, the rhymes were known as songs or ditties. James Halliwell, a British author, compiled the first large-scale collections of nursery rhymes, called The Nursery Rhymes of England (1842) and Popular Rhymes and Nursery Tales (1849). These books served as the basis of nursery rhyme collections in English until the publication in 1951 of The Oxford Dictionary of Nursery Rhymes. This work was edited by Iona and Peter Opie, a husband-and-wife team of British scholars.

Additional resources

Nursery school is a type of early childhood education program designed chiefly for children 3 or 4 years old. Nursery school helps children develop their intellectual and physical skills and learn to get along with others. In addition, the school helps them develop good health and safety habits and encourages independence. The youngsters learn through a variety of play activities supervised by teachers. Nursery schools are sometimes called pre-school programs or pre-kindergarten programs.

Nursery schools may be privately owned and operated, or publicly owned and supported by the government. Some privately owned nursery schools are operated by community or church groups. Others are run by individuals or corporations for profit. A few private nursery schools are parent-cooperative schools, which are owned and operated by parents. The parents hire a teacher, and perhaps a teacher aide, and take turns doing the other work of the school themselves. The number of nursery schools supported by government funding is increasing. Many are part of public-school systems. Most government-supported nursery schools serve children from low-income families or children with special needs, such as youngsters with disabilities.

Nursery schools differ from day-care centers, also called child care centers, which enroll older children—and sometimes infants—as well as 3- and 4-year-olds. Day-care centers chiefly care for children whose parents work. See Day care.

Nursery school instruction

Teaching methods in nursery schools differ from those of elementary and high schools. The children in nursery schools spend most of their time playing or in activities they have chosen instead of doing work assigned by the teacher.

The classroom of a nursery school also looks different. Instead of rows of chairs and desks, the room has areas called activity centers. Each center has different equipment and materials for the children to use.

Learning through play. A nursery school features long periods of play because young children learn best by playing. Preschool youngsters cannot grasp the meaning of words that represent unfamiliar objects or situations. As a result, these children learn better by direct contact with objects and other experiences than by using words alone. Nursery school children learn the

Nursery rhymes are short poems for children. This picture illustrates the nursery rhyme "Peter, Peter, Pumpkin-Eater," which tells about a man who keeps his wife in a pumpkin shell.
names, characteristics, and uses of things with which they play. The youngsters handle objects, compare them, count them, and move them around. These activities help children understand directions, distances, numbers, shapes, and sizes.

Nursery school children also develop social skills through play. They learn to cooperate with others, to share, and to resolve difficulties in a friendly way. The children also learn to express ideas and to listen to the ideas of others. As children play, teachers may make suggestions to encourage more complex play or may demonstrate problem-solving activities. Teachers ask questions to focus a child's attention on important aspects of the activities.

A number of nursery schools use a teaching technique developed by the Italian educator Maria Montessori. The Montessori method involves special learning activities that children choose for themselves and work with individually. See Montessori method.

A nursery school day provides a balance of active and quiet experiences. The children begin a typical day with an indoor activity period. During this period, they work alone or in groups at activity centers, and the teachers give individual help. Examples of activities include building with blocks or experimenting with objects in a large basin of water. Some children may pretend to be parents, police officers, or other adults. Other children draw, paint, or work with clay. Still others look at picture books or listen to recordings of stories or songs. Children may participate in a variety of activities in a day.

After the indoor activity, the teacher and teacher aide help the children clean up the classroom and put away their materials. The class might then have a snack. Next, the children might sit on the floor or on low chairs and talk with the teacher. They might chat about recent experiences or about an object that the teacher or a child has brought to school, or they may listen to a story. The class might also discuss plans for the rest of the day.

Most nursery schools also have an outdoor activity period, which helps youngsters develop strength and coordination by climbing, jumping, running, and other forms of exercise. The outdoor area might have boards, boxes, and large, movable wooden or plastic shapes that can be built into ramps, enclosures, or structures and combined in different ways for play. Most schools have sandboxes, tricycles, wagons, swings, and a structure for climbing.

The day might end with a music and movement period, during which the children sing, dance, or move to rhythm. When they are ready to go home, they often take samples of their artwork.

The nursery school teacher

The teacher's role is to provide education, care, and affection. The children receive some education directly, as when the teacher gives them information or tells stories. Other education comes indirectly, such as the creation of a learning opportunity that children can use on their own. Nursery school children are so young that the teacher must provide physical care. The teacher must also establish a warm relationship with the children and help them feel good about themselves. Youngsters need much individual attention as well.

A person who wants to be a nursery school teacher should like and respect children from all backgrounds. A teacher needs to be intelligent, well educated, and able to relate warmly to young children. The teacher should understand how children develop and how to help them learn. He or she must know how to work with parents and other adults for the welfare of children. Opportunities and training. The number of nursery schools has increased greatly since the late 1960's. Jobs for teachers are available, though many of these positions involve low salaries. Women far outnumber men as nursery school teachers, but more and more men are entering the field.

Many people prepare for a career in nursery education by studying early childhood education or child development. Most colleges and universities offer four-year programs and many community and junior colleges offer two-year programs. The programs include courses in teaching methods, the history of early childhood education, and practice-teaching. In practice-teaching, a student actually teaches in a classroom under the guidance of an experienced teacher.

History

Institutions similar to nursery schools were established during the 1800's under the name infant schools. In the early 1900's, two British sisters named Margaret and Rachel McMillan set up one of the first institutions called a nursery school. Their school, located in a slum area of London, was designed to give children of poor families the benefits that wealthy children received in home nurseries.

Nursery schools spread to the United States by the 1920's. Many colleges and universities established laboratory nursery schools. At these schools, faculty and students studied young children and tested teaching methods in addition to educating the youngsters.

During the Great Depression of the 1930's, the United States government supported nursery schools under a program called the Works Progress Administration (WPA). The WPA nursery schools provided work for many teachers who had lost their jobs during the depression.

The greatest expansion of nursery school education occurred during the 1960's, when the government established a program called Head Start. Head Start was designed to help children of low-income families prepare for school. Today, it also serves children with disabilities. It provides children with medical, nutritional, and social services as well as education.

Nursery schools in the United States

In all states of the United States, a state agency licenses and regulates nursery schools. Some states only require nursery schools to meet fire, health, and safety regulations to obtain a license, while other states have stricter standards.

Some states require a nursery school teacher to have a bachelor's degree in early childhood education, plus a teaching certificate. Other states require little more than a high school education. Teacher aides, also called teacher assistants, do not need a certificate. The teacher aides help teachers with such tasks as caring for school materials and providing individual help for the children.
Children in nursery schools participate in many activities. These children are listening as their teacher reads a story.

There are two organizations in the United States for nursery school teachers and others interested in the field. These groups are the National Association for the Education of Young Children and the Association for Childhood Education International. Mary Renck Jalongo See also Early childhood education; Head Start.

Additional resources

Nurse's aide is a person who helps nurses in hospitals perform their work. A nurse's aide is also sometimes called a ward helper, a hospital attendant, or a nursing aide.

The nurse's aide does as much of a nurse's work as possible. By doing the jobs that require little or no training, the nurse's aide allows a regular nurse to concentrate on jobs that require special skills. Nurse's aides answer patients' calls; help feed, wash, and care for them; and keep their rooms in order. If patients have to go to some other part of the hospital, nurse's aides may go along. They may help support patients during treatment, or help move them onto or off beds and stretchers. In larger hospitals, nurse's aides may act as diet assistants or as clerks.

There are two kinds of nurse's aides. The Red Cross trains volunteer workers who help out in community hospitals. Many of these volunteers are older women. But many nurse's aides are paid workers who have no training in the field of nursing. Many young people work as nurse's aides in a hospital for a while to find out whether or not they want to become nurses.

Pamela J. Maraldo
See also Nursing.

Nursing. Most nurses work in hospitals taking care of sick people and helping them get well. But nurses also work in other places. Visiting nurses go to the homes of the sick. Some nurses assist in the offices of doctors and dentists. Others work in medical clinics, in schools, in stores and factories, in the armed forces, and on ships, trains, and airplanes. Nurses may be found wherever their skills are needed—in big cities, small towns, and farm areas in all parts of the world.

In addition to caring for the sick, nurses help healthy people stay well. They teach children and adults to protect themselves from disease. Nurses who have had advanced education may also teach in schools and colleges of nursing. Some nurses with advanced clinical skills have started their own clinics, providing patients with such services as physical examinations and nutrition and mental health counseling.

The two main groups of nurses are professional nurses and technical nurses. Professional nurses are usually graduates of four- or five-year college programs. Technical nurses are graduates of two-year community college or three-year hospital programs. Another group of nurses, called practical nurses, complete a training program that generally lasts 12 months. Practical nurses perform many duties that relieve professional and technical nurses for other tasks that require more preparation.

Most nurses are women. More women serve in the field of nursing than in any other profession except teaching. However, more and more men have been entering the nursing profession. Until the 1960's, men made up only 1 percent of the total number of professional nurses. By the early 2000's, men made up over 10 percent of students enrolled in undergraduate professional programs and about 5 percent of all practicing professional nurses.

Professional and technical nurses

Hospital nurses. Most professional and technical nurses work in hospitals. They work with doctors and other medical personnel in caring for patients. Nurses function in a great variety of roles in the hospital. They work as members of the surgical team in the operating room. They work on intravenous therapy teams giving blood transfusions or injections of drugs. Nurses help patients learn to function with disabilities or illness and provide important information to assist patients when they are discharged from the hospital. Nurses also care for newborn babies.

Nurses manage the daily care of patients. They see that patients have a daily bath and that they eat proper foods. They make sure that patients do exercises or have treatments that will aid in recovery. Nurses administer prescribed medicines to patients and teach patients to care for themselves. Nurses keep a watchful eye on patients and keep track of any changes in physical condition, mental attitude, or reaction to drugs or other treatment.

The well-being of patients is of first importance to nurses. They take time to reassure worried patients and boost the patients' morale. Nurses are taught to recognize and understand patients' needs and to provide emotional support as well as physical care. For example, they take time to play with a child, read to a person who cannot see, or write letters for a patient who has a broken arm.
Most nurses work in hospitals, where they help comfort and care for people who are sick, injured, or recovering from surgery. This nurse is taking a patient’s blood pressure.

A nurse manager has charge of the nurses and patients in a unit or in a section of the hospital. With additional education, a nurse may become a supervisor and direct several units or may specialize in one kind of nursing. For example, a neonatal clinician is a nurse who specializes in the care of newborn babies. A cardiovascular specialist specializes in caring for heart patients. Specialization requires a master’s degree, which also prepares a nurse for teaching, supervision, or administration.

In other institutions, such as nursing homes and mental hospitals, nurses perform in much the same way as hospital nurses. Specialized knowledge or training usually is required because of the special needs of the patients.

Private-duty nurses work in hospitals or in private homes. Unlike other nurses, they are employed by the patient rather than by the hospital. Private-duty nurses may devote all their time to only one patient who needs constant care. Sometimes they may care for a small group of patients. Most hospitals keep a registry, or file, of nurses who are available for private duty.

Community health nurses. Community health offers increasing opportunities for nurses. Those who wish to enter this field must take special college courses that are approved for community health work. Community health nurses usually help take care of large groups of people in their homes and communities. Most of these nurses work for government or private agencies.

Visiting nurses are community health nurses. So are the nurses employed by city, county, or state health departments. Community health nurses may go into homes to care for patients who have just returned from hospitals. They often teach patients with chronic illnesses, such as cancer and diabetes, how to care for themselves. They also teach patients and their families about proper diet, personal cleanliness, and other ways of preventing illness. Community health nurses may take part in many community projects, such as polio-vaccination and immunization programs for communicable diseases. Some of them work in schools and summer camps.

Occupational, or industrial, health nurses work in factories, stores, banks, and many business offices. These nurses give first aid to the injured. They give employees physical examinations, screen them for illnesses, and treat them for colds, bruises, and other minor ailments. They also promote programs to prevent accidents on the job.

Nurse practitioners are nurses who have had additional training in a certain area of specialized practice. For example, some nurse practitioners specialize in geriatrics (caring for the aged) and others in pediatrics (caring for children). Nurse practitioners perform many functions that were once done only by physicians. These nurses give physical examinations, diagnose and treat minor illnesses, and advise patients on health problems. By administering much of the daily health care, nurse practitioners free physicians to treat patients suffering more acute ailments. Most nurse practitioners work in private clinics or doctors’ offices, or in a group practice with physicians or other nurse practitioners.

Other nursing careers. Many professional nurses combine the professions of teaching and nursing. To teach in a school of nursing, a professional nurse must

A male nurse gives medication to a patient. Although most nurses are women, more and more men are enrolling in nursing education programs or pursuing careers in practical nursing.
have advanced college preparation. A doctoral degree in nursing is usually required for teaching.

Professional and technical nurses may work in clinics or in doctors' and dentists' offices. Many nurses work as nurse researchers. They conduct research on how to relieve patient suffering. For example, nursing research has discovered how to decrease vomiting in patients who undergo chemotherapy (treatment with drugs). Some nurses hold positions in nursing organizations. Others write books and articles about nursing. Companies that manufacture drugs and medical equipment often employ nurses as consultants on their products. Nurses serve in the Army, Navy, and Air Force. Other branches of the government, such as the Department of the Army and the Department of Veterans Affairs, have nurses on their staffs.

**Practical nurses**

Practical nurses are specially educated men and women who help professional and technical nurses. They may work in hospitals, private homes, nursing homes, public health agencies, and doctors' offices.

Practical nurses often care for mothers and babies, the sick, and chronically ill people. Frequently they are responsible for such tasks as making beds, giving baths, and feeding the helpless.

**Nursing as a career**

Nursing offers daily satisfaction to those who have a genuine desire to help others. It also provides such a wide range of job opportunities that a capable nurse—especially one with an advanced degree—can always be of a job.

Among the rewards of nursing are the challenges it offers. A badly injured person may need immediate and expert care. Medicines and equipment must be rushed to the patient's bedside. The family must be comforted, and the doctor must be given a detailed report on the patient's condition. A nurse's greatest reward oftentimes is the knowledge that his or her skill has helped to relieve suffering or to save a life.

People planning a career in nursing should also consider a number of other factors. Advances are being made steadily in nurses' salaries. Nurses must be active and on their feet a great deal and may have to do some strenuous work, such as lifting patients. Special body mechanics courses taught in nursing schools help the nurse prepare for such activities.

A nurse must like people and want to help them and also must have self-reliance and good judgment. Patience, tact, honesty, responsibility, and ability to work easily with others are valuable traits. Good health is another "must."

Most professional or technical nursing schools accept only candidates who rank in the upper half or upper third of their high-school graduating classes. Entrance requirements for practical nursing are less exacting. High-school graduates are preferred, but many practical nursing schools accept candidates with two years of high-school work or less.

Costs of a nursing education program vary widely. Most hospital schools require an entrance fee and charge tuition. In most college schools of nursing, students pay tuition. They also pay for all or part of their maintenance. People who want to enter nursing should inquire about costs at the schools that they are considering attending.

**Professional and technical nursing education**

Three types of programs provide the necessary training for a career in professional and technical nursing. They are (1) associate degree programs, (2) diploma programs, and (3) baccalaureate programs. The time needed to complete a program ranges from two to five years, depending on the type of program.

Associate degree programs consist of a two-year course of study in nursing care and related subjects. These programs lead to an associate degree in nursing. Many junior and community colleges offer such programs. Students also gain practical experience by working in local hospitals and other health agencies that cooperate in the programs.

Diploma programs are offered by hospital schools. They require two or three years of study, after which the student receives a diploma. Students take nursing courses in classrooms and laboratories, and they work with patients in the hospital and at health agencies.

Baccalaureate programs offered by colleges and universities lead to a bachelor of science degree. The course work requires four to five years. It includes experience with patients in hospitals and health agencies as well as courses in nursing and in the humanities.

All nursing education programs provide both classroom training and practical experience. They prepare the student for obtaining a license to practice as a Registered Nurse.

**Classroom work.** Nursing students study such subjects as anatomy, chemistry, nutrition, pharmacology, physiology, psychology, and sociology, as well as the fundamentals of nursing care. They learn to care for the sick by working in the nursing laboratory. Frequently, the students practice on one another. For example, one
student may take another's temperature, blood pressure, and pulse rate.

Clinical experience. In all schools of nursing, classroom work or theory is interwoven with practice. Clinical experience, or practice, means the time that the student spends in learning to care for different types of patients. As part of their clinical experience, students also learn something about hospital routine and the functions of various departments, and get the "feel" of hospital life.

Nursing students have experience with all types of patients. A teacher who is an expert nurse supervises all their early activities. As students gain experience and knowledge, they work more independently.

Licensing. After graduation from an approved school of nursing, professional and technical nurses in the United States and in some Canadian provinces must pass a written examination. The nurse then receives a license to practice the profession in the state or province. She or he is now a registered nurse (R.N.).

Nurses may advance their careers by additional study and experience. A master's degree is often the step to specialization, teaching, or administration. To advance further, a nurse may earn a doctoral degree as preparation for teaching and conducting research.

Practical nursing courses usually last one year. Like professional and technical nursing education, practical nursing courses combine classroom study with actual experience.

There are two types of schools of practical nursing, public and private. Some public schools teach practical nursing as part of their vocational-training or adult-education programs. Private schools are operated by hospitals, health agencies, and by some junior colleges and universities.

Credits for courses taken at vocational nursing schools cannot be directly transferred to professional or technical nursing schools. However, some nursing school programs allow vocational nurses to obtain a degree without repeating basic courses.

In all the states, and in some Canadian provinces, a practical nurse, like a professional nurse, must obtain a license to practice. He or she then becomes a Licensed Practical Nurse (L.P.N.), sometimes called a Licensed Vocational Nurse (L.V.N.).

Career information. A high-school student who wants to learn about a nursing career should talk with a vocational guidance counselor, school nurse, or other nurses. Many high schools have Future Nurses clubs whose members visit hospitals and schools of nursing and do volunteer work. Serving as a nurse's aide or as an orderly in a hospital is another way to learn more about nursing (see Nurse's aide). Information on professional, technical, and practical nursing may be obtained from the National League for Nursing in New York City.

The history of nursing

Some form of nursing care has probably been practiced for thousands of years. For example, the early Israelites and Egyptians hired women, later called midwives, who assisted at births.

Nurses first organized in groups during early Christian times. Noblewomen, including the wives of the emperors, helped care for the ill in ancient Rome. During the Crusades, military nursing orders of monks and knights tended the sick and wounded.

Many monasteries closed during the Reformation, and there were only a few places where religious orders could nurse the sick. The years from 1600 to 1850 were the darkest period in the history of nursing. Hospitals often were built as charity hospitals and were usually staffed by untrained, sometimes disreputable, women. Wealthy people never went to hospitals. The importance of sanitation and hygiene was unknown. People did not understand how disease spread. Nurses who took care of patients with contagious diseases often contracted these diseases themselves.

Nursing as we know it began in the 1850's with the work of the English nurse Florence Nightingale, the founder of modern professional nursing. Nightingale established the first school of nursing, the Nightingale Training School for Nurses, in London in 1860. Graduates of this school traveled to all parts of the world to teach nursing.

The first nursing schools in the United States were established in 1873 at Massachusetts General Hospital in Boston, Bellevue Hospital in New York City, and the New Haven (Connecticut) Hospital. The American Nurses' Association, Inc., an organization of registered nurses, was organized in 1896.

Many nurses have won world fame. They include Clara Barton, Edith Cavell, Elizabeth Kenny, and Lillian D. Wald.

Donahue, M. Patricia. Nursing, the Finest Art: An Illustrated History. 2nd ed. Mosby, 1996.

Nursing home is a residential institution that provides medical or nonmedical care, chiefly for people who are 65 years old or older. Nearly all homes also accept younger patients. In the United Kingdom, some private maternity hospitals are called nursing homes. The best nursing homes strive to provide a comfortable, home-like environment for their residents.

Most nursing homes are privately owned. Others are operated by federal, state, provincial, or local governments. Some private nursing homes are run by corporations, which try to earn a profit for the owners. Others are sponsored by religious or civic groups, which do not have a primary goal of making money.

Most countries have laws governing the operation of nursing homes and require the institutions to have a license. Inspectors visit the homes periodically to make sure they follow these laws.

Types of nursing homes

There are three types of nursing homes: (1) skilled nursing care homes, (2) intermediate care facilities, and (3) supervised assisted living facilities. They differ according to the types of patients they care for and the
inds of services they offer. **Skilled nursing care homes** provide more extensive services than the other types of nursing homes. For example, they offer diagnostic, laboratory, and medication services; therapy programs; and dental care. Registered nurses supervise the care of patients according to the instructions of the institution's medical director. Physicians visit these homes frequently. Most skilled nursing care homes are run by licensed administrators.

Most of the patients in skilled nursing care homes require medical attention around the clock. Some have serious illnesses or disabilities. Others stay in these institutions after being hospitalized. They receive additional treatment before returning home.

Most skilled nursing care homes have transfer agreements with hospitals, intermediate care facilities, and other health care institutions. Patients who become so ill that they need more medical care than a nursing home can provide are taken to a hospital. Those whose health improves, but who still require some nursing care, are transferred to an intermediate care facility or other health care institution.

**Intermediate care facilities**, also called basic nursing care homes, provide basic nursing services. Registered nurses examine the residents periodically to determine what treatment is needed. Most patients in intermediate care facilities suffer from a long-term illness, such as Alzheimer's disease or Parkinson's disease. However, they require only minor medical care. Doctors visit these nursing homes regularly.

Registered nurses direct the nursing programs in intermediate care facilities, but an administrator runs these institutions.

**Supervised assisted living facilities** provide nonmedical services. These services include preparing and serving the residents' meals and helping the men and women care for themselves. For example, members of the staff assist residents who have difficulty dressing themselves. The institutions also plan outings and other social activities for the residents.

Most residents of assisted living facilities need only routine medical examinations, and physicians visit these homes only when necessary. A supervisor of residential care directs the services provided.

**Selecting a nursing home**

**Quality of care.** In selecting a nursing home, it is important to match both the medical and psychological needs of a person with the resources of the caregiving institution. For example, not all older adults require the same amount of medical care. A study of nursing homes revealed that a number of relatively healthy people lived in institutions that had extensive medical facilities. The study also found that many people who needed medical attention lived in nursing homes that did not have adequate medical services.

Nursing homes also should provide for the psychological needs of their residents. Most people in nursing homes can still lead productive lives. However, some low-quality institutions have few or no activities for residents. The best nursing homes encourage residents to stay active and to participate in a variety of community service and social activities.

**Emotional effects.** Many families feel guilty about placing an elderly relative in a nursing home. In most cases, they agree to this action only as a last resort. They do so when the person's health problems grow too severe and the family's social and financial resources become too strained to keep the relative at home.

Many elderly people suffer stress when they must adjust to the unfamiliar environment of a nursing home. Some older people regard it as the final step before death. The strain of the move can result in depression, increased health problems, and, in certain cases, even death.

There are several ways to lessen the strain on older people, including involving them in the decision to move to a nursing home and in the choice of a facility. The institution should allow patients to keep personal belongings in their new room. It is also important to choose a home where the staff is well trained and concerned about the patients. Nancy P. Kroep

See also Day care; Foster care; Hospital; Old age. **Nut**, Egyptian goddess. See Mythology (Egyptian mythology).

**Nut** is the popular name for many kinds of dry, edible seeds or fruits that grow in a woody shell. The word *nut* can refer to both the shell and the nutmeat, or kernel, inside or to the kernel alone. Nut-bearing plants grow in almost every part of the world.

Botanists define a nut as a dry, one-seed fruit surrounded by a hard shell that does not open on its own. Many edible nuts, including filberts and walnuts, are true nuts. But people also eat other kinds of nuts, such as almonds, coconuts, and peanuts, that are not true nuts. In fact, peanuts are related to peas (see *Peanut*).

**Uses of nuts.** Most people eat nuts as snacks or use them as flavoring in cooking. Many peanuts are used in peanut butter, candies, and cookies. Most nuts are rich in protein and fat, though chestnuts and a few others have more starch than protein. In Italy, bread is sometimes baked with a flour made from chestnuts.

Prehistoric people probably ate nuts as a regular part of their diet. Some nutritionists believe that, because of food shortages, nuts will again become a widely used source of protein.

In addition to their value as food, some nuts provide useful oil. For example, peanut oil and walnut oil are used in cooking. Walnut oil is also used to clean and polish wooden furniture. Jojoba nuts furnish a valuable lubricant for precision instruments. Tung oil is used in paints and varnishes.

**Kinds of nuts.** Hundreds of species of shrubs and trees produce nuts, but only about 25 kinds of nuts are raised as crops. In the United States, nut growers produce more peanuts than any other type of nut. Almonds rank second in production, followed by English walnuts, also called Persian walnuts; pecans; black walnuts; filberts, or hazelnuts; and macadamia nuts.

The leading peanut-growing countries are China, India, Nigeria, and the United States. Growers in Georgia produce most of the U.S. peanut crop. California produces about one-third of the world's almonds, plus large crops of English walnuts and pistachios. Pecans, a type of hickory nut, are raised in many Southern and Western states. Pecans are also raised in Australia, Mexico, South Africa, and the Middle East.

Black walnuts grow in the Midwest and East. Unlike most kinds of commercial nuts, which are raised in orchards, black walnuts are collected from wild trees. Filberts grow on large shrubs or small trees and are a major crop in Oregon and in Italy, Spain, and Turkey.

Chestnuts are produced in China, Italy, Japan, Korea, and Turkey. A disease killed almost all American chestnut trees during the early 1900s.

Macadamia trees were first brought to Hawaii from Australia in the late 1800s. Today, Hawaii ranks as the world’s chief producer of macadamia nuts. Brazil nuts grow in the Amazon River region of South America. Other tropical nuts include cashews and coconuts.

Nut growing. Most kinds of nut trees produce nuts only if they have been cross-pollinated—that is, pollinated by flowers from another tree of the same species.

Nut growers raise new trees by grafting certain parts of one tree to the roots of another (see Grafting).

Nut trees—and nuts themselves—may be damaged by a number of pests and diseases. For example, mice, squirrels, weevils, and some species of birds eat nuts and feed on nut crops. Nut trees can be harmed by certain insects and diseases that attack the leaves, stems, or nuts. Nut growers commonly protect their crops from insects and diseases by spraying the trees with pesticides. They use firearms, mechanical barriers, poisons, repellents, traps, and various other means to control birds and rodents.

Nutcracker is the name of two species of birds. Clark nutcracker lives in evergreen forests in the mountains of western North America. It is gray with black and white wing and tail feathers and is 12 inches (30 centimeters) in length. The Eurasian nutcracker is found in similar regions in Europe and Asia. It is reddish-brown with white markings, and it has black wings. Nutcrackers have a strong, direct flight.

Clark’s nutcracker feeds chiefly on the seeds of pine cones. It holds the cones in its sharp, heavy, curved claws while opening them with its bill. The Eurasian nutcracker feeds on the seeds of pine cones and hazelnuts. Both species also eat insects, berries, and the eggs of other birds. They often store seeds and nuts for use during the winter.

Clark’s nutcracker hides its nest at the top of a tall pine. During winter, the female lays from three to five speckled, grayish-green eggs. Both Clark’s nutcracker parents care for the eggs and the young.

Sandra L. Vehrencamp

Scientific classification. Nutcrackers belong to the crow family, Corvidae. The scientific name for Clark’s nutcracker is Nucifraga caryocatactes. The Eurasian nutcracker is N. caryocatactes.

Nuthatch is the name of a group of tree-climbing songbirds. They are common throughout the temperate regions of the world. Nuthatches get their name from their habit of wedging nuts into cracks in tree bark and then hatching (opening) them with repeated strokes of the bill. Unlike other climbing birds, nuthatches often creep down tree trunks headfirst.

- The best-known North American species is the white-breasted nuthatch. This bird lives year-round in the United States and southern Canada and can be found in...
woodlands, orchards, and yards. It measures about 5 to 6 inches (13 to 15 centimeters) in length. The top of its head and upper neck are black, its back is dark gray, and its underparts are white.

White-breasted nuthatches eat nuts and grain, as well as insects and insect larvae that they find underneath the bark of trees. In winter, these birds are easily attracted to feeding stations, where they eat sunflower seeds and suet (animal fat). The white-breasted nuthatch builds its nest in holes in trees or stumps. The female lays from 5 to 10 white eggs that are speckled with reddish-brown or lavender markings.

Other North American nuthatches are the red-breasted nuthatch, which lives in southern Canada and the northern and western parts of the United States; the brown-headed nuthatch, found in the Southern States; and the pygmy nuthatch, found in western North America and in Mexico. These species are smaller than the white-breasted nuthatch.

Scientific classification. Nuthatches belong to the nuthatch family, Sittidae. The scientific name for the white-breasted nuthatch is Sitta carolinensis. Martha Hatch Ralph

See also Bird (pictures: Birds of forests and woodlands; Birds’ eggs).

Nutmeg is a tropical tree that is grown commercially for the spice it provides. The spice, also called nutmeg, comes from the inner part of the tree’s brown seeds. The seeds develop in small fruits that look like golden-yellow pears when ripe. Nutmeg trees are native to the Molucca (Spice) Islands. They are now raised in Indonesia, the West Indies, Brazil, India, and Sri Lanka.

The nutmeg tree grows up to 70 feet (21 meters) tall and is an evergreen. It has gray-green leaves that are long and pointed with well-marked veins. The small, pale-yellow flowers droop in clusters and develop into fruit. As the fruit ripens, the fleshy part becomes rather hard. It finally splits open showing a bright-scarlet membrane that partly covers the kernel of the seed. The spice called mace comes from this membrane (see Mace). Nutmeg is made by grating or grinding the kernels. It has a sweet, spicy flavor.

Nutmeg trees do not bear fruit until they are about nine years old. Each tree produces from 1,500 to 2,000 seeds yearly. The fleshy part of the fruit is sometimes preserved and eaten like candy. A clear oil called oil of nutmeg is made from the kernels.

Scientific classification. Nutmeg trees belong to the nutmeg family, Myristicaceae. Their scientific name is Myristica fragrans. David S. Seigler

Nutmeg State. See Connecticut (Colonial life).

Nutria, NOO tree uh, or coypu, K0Y poo, is a large rodent that lives near water. Nutrias are native to South America. They were introduced into many parts of Europe and North America to be raised for their fur. How-

Nutrias are large aquatic rodents that originated in South America. The animals are valued for their brown, beaverlike fur. ever, most attempts to raise nutrias commercially have not been profitable.

The nutria has brown fur with a whitish-tipped muzzle. It has small ears; webbed hind feet; and a long, scantly haired tail. The tail makes up nearly half the total body length, which measures up to 40 inches (100 centimeters). Wild nutrias may weigh up to 20 pounds (9 kilograms).

Nutrias live along the banks of lakes, marshes, ponds, and rivers. They are excellent swimmers. They feed chiefly on water plants. Female nutrias give birth to an average of four or five young at a time.

Nutrias are serious pests in some regions of the Southeastern United States. They dig holes in earthen dams and dikes and disrupt the balance of nature by destroying water plants. They also damage rice and sugar cane crops.

Nutrias are trapped in Louisiana. The fur is made into coats and gloves. The meat is used for pet food.

Scientific classification. The nutria belongs to the family Myocastoridae. Its scientific name is Myocastor coypus. Hugh H. Genoways
A balanced diet is the key to good nutrition. It supplies all the food substances the body needs. The family shown here enjoys a breakfast that includes fruit, cereal, bread, and milk. The daily diet should include several servings of these foods.

Nutrition

Nutrition is the science that deals with food and how the body uses it. People, like all living things, need food to live. Food supplies the energy for every action we perform, from reading to running. Food also provides substances that the body needs to build and repair its tissues and to regulate its organs and systems.

What we eat directly affects our health. A proper diet helps prevent certain illnesses and aids in recovery from others. An improper or inadequate diet increases the risk of various diseases. Eating a balanced diet is the best way to ensure that the body receives all the food substances it needs. Nutrition experts recommend that the daily diet include a certain number of servings from each of the five major food groups: (1) breads, cereals, rice, and pasta, (2) vegetables, (3) fruits, (4) milk, yogurt, and cheese, and (5) meat, poultry, fish, dried beans and peas, eggs, and nuts. Fats are also essential, but, like sweets, should be eaten in small quantities.

Workers in the field of nutrition oversee school food services, plan menus for hospitalized patients, and provide nutrition counseling for individuals. They administer international food programs and investigate the relationship between diet and health. They seek improved ways of processing, packaging, and distributing foods, and they create new foods.

How the body uses food

Food provides certain chemical substances needed for good health. These substances, called nutrients, perform one or more of three functions: (1) They provide materials for building, repairing, or maintaining body tissues; (2) They help regulate body processes; and (3) They serve as fuel to provide energy. The body needs energy to maintain all its functions.

The body breaks food down into its nutrients through the process of digestion. Digestion begins in the mouth. As food is being chewed, saliva moistens the particles. The saliva begins to break down such starchy foods as bread and cereals. After the food is swallowed, it passes through the esophagus, a tube that leads into the stomach. In the stomach, digestive juices speed up the break down of such foods as meat, eggs, and milk.

The partly digested food, called chyme (pronounced kym), passes from the stomach into the small intestine. In the small intestine, other juices break down the food into molecules that pass through the walls of the intestine and into the blood.

Blood distributes nutrients throughout the body. In the body’s cells and tissues, the nutrients are broken down to produce energy, or are used to rebuild tissues or to regulate chemical processes. Some nutrients are stored in the body, and others are used over and over again. But most of the nutrients undergo chemical changes as they are used. These chemical changes produce waste products, which go into the bloodstream.

Some of these wastes are carried to the kidneys, which filter them from the blood. The body expels these wastes in the urine. The liver also filters out some wastes and concentrates them into a liquid called bile. Bile addition to concentrating certain wastes, bile helps digest fats.

Bile is stored in the gall bladder until it is needed to aid in digestion. Then the gall bladder empties bile into the small intestine. Bile then passes into the large intes-
Nutritionists classify nutrients into six main groups: (1) water, (2) carbohydrates, (3) fats, (4) proteins, (5) minerals, and (6) vitamins. The first four groups are called macro-nutrients, from a Greek prefix meaning large, because they provide energy. Food energy is measured in units called kilocalories. A kilocalorie is equal to 1,000 calories. A calorie is the energy required to raise the temperature of one gram of water one Celsius degree. However, kilocalories are often referred to as simply "calories." The "calories" mentioned in this article are actually kilocalories.

Water is needed in great amounts because the body consists largely of water. Usually, between 50 and 75 percent of a person's body weight is made up of water.

The body requires large quantities of carbohydrates, fats, and proteins because these nutrients provide energy. Food energy is measured in units called kilocalories. A kilocalorie is equal to 1,000 calories. A calorie is the energy required to raise the temperature of one gram of water one Celsius degree. However, kilocalories are often referred to as simply "calories." The "calories" mentioned in this article are actually kilocalories.

Although minerals and vitamins are needed in only small amounts, they are as vital to health as any other nutrients. Minerals and vitamins are needed for growth and to maintain tissues and regulate body functions.

Proteins provide energy—4 calories per gram, as carbohydrates do—but more importantly, proteins serve as the main building materials of the body. Muscle, skin, cartilage, and hair, for example, are made up largely of proteins. In addition, every cell contains proteins called enzymes, which speed up chemical reactions. Cells could not function without these enzymes. Proteins also serve as hormones (chemical messengers) and as antibodies (disease-fighting chemicals).

Proteins are large, complex molecules made up of smaller units called amino acids. The body must have a sufficient supply of 20 amino acids. It can manufacture enough of 11 of them. Nine others, called essential amino acids, either cannot be made by the body or cannot be manufactured in sufficient amounts. They must come from the diet.

The best sources of proteins are cheese, eggs, fish, lean meat, and milk. Proteins in these foods are called complete proteins because they contain adequate amounts of all the essential amino acids. Cereal grains, legumes (peanuts and other plants of the pea family), nuts, and vegetables also supply proteins. These proteins are called incomplete proteins because they lack adequate amounts of one or more essential amino acids. However, a combination of two incomplete proteins can provide a complete amino acid mixture. For example, beans and rice are both incomplete proteins, but together they provide the correct balance of amino acids.

Minerals are needed for the growth and maintenance of body structures. They are also needed to maintain the composition of digestive juices and the fluids that are found in and around cells. People need only small amounts of minerals each day.

Unlike vitamins, carbohydrates, fats, and proteins,
minerals are inorganic compounds—that is, they are not created by living things. Plants obtain minerals from the water or soil, and animals get minerals by eating plants or plant-eating animals. Unlike other nutrients, minerals are not broken down by the body.

Required minerals include calcium, chlorine, magnesium, phosphorus, potassium, sodium, and sulfur. Calcium, magnesium, and phosphorus are essential for healthy bones and teeth. Calcium is also necessary for blood clotting. Milk and milk products are the richest sources of calcium. Cereals and meats provide phosphorus. Whole-grain cereals, nuts, legumes, and green leafy vegetables are good sources of magnesium.

Still other minerals are needed only in extremely tiny amounts. These minerals, called trace elements, include chromium, copper, fluorine, iodine, iron, manganese, molybdenum, selenium, and zinc. Iron is an important part of hemoglobin, the oxygen-carrying molecule in red blood cells. Copper helps the body make use of iron to build hemoglobin. Manganese and zinc are required for the normal action of various enzymes. Green leafy vegetables, whole-grain breads and cereals, seafood, and liver are good sources of trace elements.

Vitamins are essential for good health because they regulate chemical reactions in which the body converts food into energy and tissues. There are 13 vitamins: vitamin A; the vitamin B complex, which is a group of 8 vitamins; and vitamins C, D, E, and K. Scientists divide vitamins into two general groups, fat-soluble vitamins and water-soluble vitamins. The fat-soluble vitamins—vitamins A, D, E, and K—dissolve in fats. The vitamins of the B complex and vitamin C dissolve in water. Small amounts of these compounds are needed daily.

Vitamin A is necessary for healthy skin and development of strong bones. Sources of this vitamin include liver, green and yellow vegetables, and milk.

Vitamin B₁, also called thiamine, is necessary for changing starches and sugars into energy. It is found in meat and whole-grain cereals.

Vitamin B₂, also known as riboflavin, is essential for complicated chemical reactions that take place during the body's use of food. Milk, cheese, fish, liver, and green vegetables supply vitamin B₂.

Vitamin B₃, also called pyridoxine, and two other B vitamins known as pantothenic acid and biotin all play a role in chemical reactions essential for growth. Liver, yeast, and many other foods contain these vitamins.

Vitamin B₆, folic acid, and biotin, also called folate, are both needed for forming red blood cells and for a healthy nervous system. Vitamin B₆ is found in animal products, especially liver. Folic acid is present in green leafy vegetables. Doctors recommend that all women who are capable of becoming pregnant consume small amounts of folic acid each day to reduce the risk of spina bifida, a serious birth defect.

Niacin is also part of the B complex. Cells need niacin to release energy from carbohydrates. Liver, yeast, lean meat, fish, nuts, and legumes contain niacin.

Vitamin C, also called ascorbic acid, is needed for the maintenance of ligaments, tendons, and other supportive tissue. It is found in fruits and in potatoes.

Vitamin D is necessary for the body's use of calcium. It is present in fish-liver oil and vitamin D-fortified milk. Vitamin D also forms when skin is exposed to sunlight.

Vitamin E, also known as tocopherol, helps maintain cell membranes. Vegetable oils and whole-grain cereals are especially rich in this vitamin. It is also found in small amounts in most meats, fruits, and vegetables.

Vitamin K is necessary for proper clotting of blood. Green leafy vegetables contain vitamin K. It is also manufactured by bacteria in the intestine.

Nutrition guidelines

Eat a balanced diet. The key to good nutrition is a varied diet that includes every kind of nutrient. To aid in planning a balanced diet, nutritionists have devised systems that group foods according to nutrient content. The Food Guide Pyramid pictured in this article is one such system, developed by the United States Department of Agriculture (USDA). The pyramid shape calls attention to the recommended amounts to eat from each of the major food groups. The groups at the broad base of the pyramid—that is, grains, fruits, and vegetables—should form the largest part of a healthful diet. Fewer daily servings should be chosen from meat and dairy groups near the top. Fats, oils, and sweets, at the narrow tip of the pyramid, should be eaten sparingly.

In the United States, the Food and Nutrition Board of the National Academy of Sciences Issues Recommended Dietary Allowances (RDA's). RDA's are estimated amounts of various nutrients needed daily to avoid deficiency and maintain good nutrition in healthy people. The board issues a standard called adequate intake (AI) in cases where the board's experts feel there is insufficient evidence to establish an RDA. RDA's and AIs for particular nutrients may vary, depending on a person's sex or age. This article includes a table of certain RDA's.

RDA's and AIs are part of a larger category of standards called dietary reference-intakes (DRIs). DRIs also include guidelines called tolerable upper intake levels (UL's). UL's define the maximum daily intake that is unlikely to harm health. DRIs are being developed in a joint effort by the U.S. Food and Nutrition Board and Health Canada. The World Health Organization is creating a set of similar standards.

The Nutrition Labeling and Education Act of 1990 requires that all packaged and processed food sold in the United States carry labels with nutritional information. These labels help people compare the nutritional content of the foods they eat with their daily dietary needs. Nutrition labels list the amounts of fats, carbohydrates, cholesterol, and certain other nutrients in one serving of the labeled food. The nutrients listed are those considered most important to health, as determined by the U.S. Food and Drug Administration (FDA). The label also provides a Daily Value percentage for each nutrient to show how it fits into a healthful diet. The percentages are based on guidelines called Daily Reference Values (DRV's); which the FDA established as the amounts of these nutrients that a healthy person should consume each day.

In addition, health claims, such as "reduces risk of heart disease," and descriptive terms, such as "fresh" and "low fat," can appear on food packages only in accordance with FDA regulations. A list of some of these descriptive terms and an illustration of a standard nutrition label accompany this article.

People vary in their needs for energy. A person who
The U.S. Department of Agriculture developed the Food Guide Pyramid to show recommended proportions of the major nutrient groups in a healthful diet for people 6 to 70 years old. People should eat more servings from groups at the bottom of the pyramid—grains, fruits, and vegetables—than from the meat and dairy groups near the top. Fats, oils, and sweets should be eaten in the smallest amounts.

**Fats, oils, and sweets group:** provides essential fatty acids and energy
Use sparingly

**Milk, yogurt, and cheese group:** provides vitamin A, vitamin B₂, calcium, and protein
2 to 3 servings daily
One serving equals:
1 cup (236 milliliters) skim or low-fat milk
1 cup (236 milliliters) low-fat yogurt
1 ½ ounces (43 grams) natural cheddar or other hard cheese

**Vegetable group:** provides vitamin A, the B vitamins, vitamin C, calcium, iron, and fiber
3 to 5 servings daily
One serving equals:
1 cup (236 milliliters) salad greens
½ cup (118 milliliters) cooked vegetable
½ cup (118 milliliters) raw, nonleafy vegetable
½ cup (177 milliliters) vegetable juice

**Meats, poultry, fish, dry beans, eggs, and nuts group:** provides protein, iron, and vitamin B₂
2 to 3 servings daily
One serving equals:
1 egg
2 to 3 ounces (57 to 85 grams) cooked chicken or other lean meat
2 tablespoons (30 milliliters) peanut butter
½ cup (118 milliliters) cooked dried beans

**Fruit group:** provides vitamin C and fiber
2 to 4 servings daily
One serving equals:
1 apple, banana, or similar whole fruit
½ cup (118 milliliters) canned fruit
½ cup (177 milliliters) fruit juice
½ cup (59 milliliters) raisins or other dried fruit

**Bread, cereal, rice, and pasta group:** provides complex carbohydrates, an important source of energy
6 to 11 servings daily
One serving equals:
1 slice bread
1 ounce (28 grams) breakfast cereal
½ cup (118 milliliters) cooked rice or pasta
2 pancakes
plays sports daily, for example, needs more calories than someone who does little physical work. Children need more calories than their size would indicate because they are growing. Pregnant women need extra calories to provide enough nutrients for a healthy baby.

**Include fiber.** Dietary fiber consists of complex carbohydrates that cannot be absorbed by the body. Fiber passes out of the body as waste. Fiber moves food along through the stomach and intestines, thus helping to prevent constipation (difficulty in emptying the bowels). Many experts believe that fiber also helps reduce the risk of such rectal and intestinal disorders as hemorrhoids, diverticulitis, and, possibly, cancers of the colon and rectum. Good sources of fiber include whole-grain breads and cereals, beans, peas, vegetables, and fruit.

**Limit intake of saturated fats, trans fats, and cholesterol.** Health experts recommend a diet that is low in saturated fats, trans fats, and cholesterol, a waxy substance found in many animal foods. Consumption of these substances raises the level of cholesterol in a person's blood, which increases the risk of heart disease. Animal products are the source of all dietary cholesterol and most saturated fats except coconut oil and other tropical oils. To reduce intake of saturated fats and cholesterol, experts suggest choosing lean meats, fish, poultry with the skin removed, and low-fat dairy products. They also advise using fats and oils sparingly. Trans fats occur chiefly in solid margarines and certain processed foods. Nutrition labels do not list trans fats. But the words **partially hydrogenated** in a product's ingredients often indicate that trans fats are present.

**Limit intake of sodium and sugar.** A diet that includes a great deal of sodium may increase the risk of high blood pressure. Sodium is found in many foods, including canned vegetables, frozen dinners, pickles, processed cheese, table salt, and such snack foods as pretzels, chips, and nuts. One way to reduce sodium intake is to use herbs and other seasonings instead of salt in cooking and at the table. Another way is to select fresh foods rather than canned or frozen items.

Foods that contain much sugar are often high in calo-

**Obesity** may result from poor nutrition. Medical personnel should be consulted to develop and monitor a weight-loss program involving both diet and physical exercise.

**Ries and fat but low in minerals, proteins, and vitamins.** Nutritionists sometimes call these foods "empty calorie" foods, because they may make a person feel full but provide few nutrients. In addition, sugar that remains in and around the teeth contributes to tooth decay. Foods that have a large amount of sugar include candies, pastries, many breakfast cereals, and sweetened canned fruits. In place of sugary foods, nutritionists advise people to snack on fresh fruits and vegetables. They also recommend that people drink unsweetened juices instead of soft drinks.

**Beware of alcohol.** Alcoholic beverages supply calories, but they provide almost no nutrients. In addition, alcohol is a powerful drug, and habitual drinking can lead to serious health problems. Health experts recommend that people who choose to drink alcoholic beverages consume only small amounts. They further recommend that certain people avoid alcohol altogether, including children and adolescents; pregnant women; people who are about to drive; anyone who is taking medicine; and individuals who are unable to limit their drinking.

Above recommendations designed for the maintenance of good nutrition of practically all healthy people in the United States.

*Adapted from (A). The AI is a value based on experimentally derived intake levels or approximations of observed mean nutrient intakes by a group or groups of healthy people. Because there is less information on which to base allowances, these figures are not classified as RDA's.

**Food labels**

All packaged and processed foods sold in the United States must carry a label with the title *Nutrition Facts*. An example of a standard food label is illustrated below. Foods in small packages or foods that contain limited nutrients may carry a simplified version of this label. Fresh fruits and vegetables, single-ingredient raw meats, and a few other foods are not required to carry labels.

**Calories per gram:**

| Fat 9 • Carbohydrate 4 • Protein 4 |

---

**Serving size** reflects the amount people customarily eat as one portion. It must be stated in both household and metric measures.

The list of nutrients consists of those nutrients considered to be of special importance to the health of people in the United States, as determined by the Food and Drug Administration. In general, Americans need to avoid getting too much of certain nutrients, particularly fat, rather than too few vitamins and minerals. The nutrients shown here must be listed on all full-sized labels. They are measured in grams (g) and milligrams (mg), rounded to the nearest whole number.

---

Daily Value is the total amount of the nutrient that a person should eat in one day as part of a healthy diet. Daily Values are provided for diets of 2,000 and 2,500 calories a day. The values for fats, cholesterol, and sodium are the maximum amounts a person should eat each day. The values for carbohydrates are the minimum amounts.

---

**Terms used in labeling food**

Certain descriptive terms can appear on food packages only if the food meets requirements set by the Food and Drug Administration. A list of some of these terms follows.

- **ree** means the food contains nutritionally insignificant amounts of the specified nutrient. For example, a can of chicken soup labeled "sodium-free" must contain no sodium or an insignificant amount of sodium.
- **resh**, as in 'fresh orange juice,' means the food is raw, contains no preservatives, and has not been processed, heated, or canned.
- **healthy** means the food is low in fat and saturated fat and contains no more than 480 milligrams of sodium and 60 milligrams of cholesterol per serving.
- **igh**, as in "high in fiber" or "high in protein," means the food provides 20 percent or more of the Daily Value of the specified nutrient per serving.
- **san** applies to meats, poultry, and seafoods that contain fewer than 10 grams of fat, 4 grams of saturated fat, and 95 milligrams of cholesterol per serving.
- **less** means the food contains at least 25 percent less of the specified nutrient than does a similar, specified food. For example, a package of pretzels could be labeled "less fat than potato chips," provided that the pretzels have at least 25 percent less fat.
- **Light** or **lite**, as in "lite sour cream," means the food has been altered during processing to contain one-third fewer calories or one-half less fat or sodium than the regular product.
- **Low**, as in "low fat" or "low sodium," means the food can be eaten frequently without exceeding Daily Value guidelines for the specified nutrient.
- **More** means the food contains at least 10 percent more of the Daily Value for the specified nutrient than does a similar, specified food. For example, grapefruit juice could be labeled "more vitamin C than orange juice," provided the grapefruit juice has at least 10 percent more vitamin C.
- **Source of** or **good source of**, as in "source of calcium" or "good source of fiber," means a serving has 10 to 19 percent of the Daily Value of a particular nutrient.
Do not overeat. When people consume more calories than they need, their bodies store most of the extra calories as fat. Accumulation of fat can result in obesity, a condition in which a person has too much body fat for good health. Obesity increases the risk of such diseases as adult-type diabetes, stroke, high blood pressure, gall bladder disease, heart disease, and certain cancers. Conditions such as osteoarthritis and low back pain may be worsened by the pressure of excess weight.

A number of techniques may help people avoid obesity. Most health experts recommend that people exercise regularly to help control their weight. Another strategy is to avoid using food as a reward or as a way to overcome loneliness or boredom. Experts also advise against snacking on foods that are high in fat or sugar. Instead, they recommend such choices as fruits or vegetables, unsalted crackers, nonfat yogurt, and unsweetened fruit juice, skim milk, or sparkling water.

Store and cook foods properly to retain their nutritional value. For example, many fresh foods should be kept in the refrigerator. They should be washed thoroughly and eaten as soon as possible. Frozen foods must be kept frozen in a freezer.

Vegetables should be cooked quickly in as little water as possible to minimize vitamin loss in the water. Avoid frying meats and other animal foods. Instead, cook them by broiling, stir-frying, braising, or poaching. These methods result in food that is tasty but free of added fat and extra calories. Microwave cooking reheats food quickly and keeps nutrient values high.

Evaluate claims about foods and dietary supplement carefully. People should use caution, common sense, and critical thinking to evaluate popular ideas or advertising claims about foods and dietary supplements. Some ideas about foods and supplements become popular even though they are wrong. For example, some people believe that they need not eat a balanced diet if they take a vitamin pill every day. But, in fact, people who rely on vitamin pills may not get all the calories, minerals, or proteins that they need.

Although labeling and advertising claims are regulated by federal agencies, people may develop mistaken ideas from claims that meet legal requirements. For example, some people think they can eat unlimited quantities of foods labeled "low fat." In fact, careful comparison of labels shows that many low-fat foods contain almost as many calories as do versions not labeled low-fat.

People should carefully consider the source of nutritional claims. Reliable sources of information include state, provincial, and national health and nutrition agencies; public departments of agriculture; and universities with expert knowledge in health and nutrition.

Nutrition and disease

An improper or inadequate diet can lead to a number of diseases. On the other hand, good nutritional habits can help prevent certain diseases.

Heart disease in its most common form is called coronary artery disease (CAD). CAD narrows coronary arteries and so reduces the blood supply to the heart. It can lead to crippling attacks of chest pain and, eventually, to life-threatening heart attacks. High blood pressure and high levels of blood cholesterol are two of the major risk factors for CAD. In many cases, people can lower these risk factors with good nutritional practices.

Many people can reduce mild high blood pressure by limiting their intake of salt and calories. Similarly, many people can lower their blood cholesterol level by reducing the amount of fat—particularly saturated fat—cholesterol, and calories in their diet. They can achieve these reductions by avoiding such foods as butter, cakes, cookies, egg yolks, fatty meats, tropical oils, and whole-fat dairy products.

Cancer. Scientists have found that heredity, environment, and lifestyle all play a role in causing cancer. They have also learned that good nutrition can help prevent certain kinds of cancer in laboratory animals. Large doses of vitamins A and C have been shown to prevent some cancers in animals. Many scientists believe that certain foods contain substances that may help prevent some cancers in people. Such foods include broccoli, cabbage, carrots, cauliflower, fruits, spinach, whole-grain breads and cereals, cooked tomatoes, and some seafood. Lessening intake of fats and increasing the intake of fiber may also help prevent some cancers.

Deficiency diseases result from an insufficient amount of certain nutrients in the diet. Such diseases can usually be eliminated when adequate amounts of the nutrient are provided. Deficiency diseases are most widespread in less developed countries, where people may lack adequate food. These diseases are less common in most developed countries, where a variety of foods are available all year, and many foods are fortified with vitamins and minerals.

Protein-calorie malnutrition, also called protein-energy malnutrition, occurs when the diet is low in both proteins and calories. If the diet is especially low in proteins, the condition is called kwashiorkor. Signs of kwashiorkor include changes in the color and texture of the hair and skin; swelling of the body; and damage to the intestines, liver, and pancreas. The disease, which is common in some less developed nations, usually attacks children who are suffering from an infectious disease. Kwashiorkor is fatal unless the patient is given protein along with food providing calories. If the diet is especially low in calories, the condition is called marasmus. Marasmus usually attacks infants and young children, and it causes extreme underweight and weakness.

Vitamin deficiencies. The signs and symptoms of

A diet especially low in proteins may cause kwashiorkor, a disease that generally strikes children. In severe cases, the muscles waste away and the skin swells with body fluids.
vitamin deficiencies vary according to the missing vitamin. Vitamin C deficiency, also called scurvy, causes sore and bleeding gums, slow repair of wounds, and painful joints. Vitamin D deficiency, also called rickets, causes abnormal development of bones. A deficiency of niacin and the amino acid tryptophan, found in protein, causes pellagra. The early symptoms of pellagra include weakness, lack of appetite, diarrhea, and indigestion.

**Mineral deficiencies.** The most common mineral deficiency disease is iron-deficiency anemia. In this disease, lack of iron prevents formation of enough oxygen-carrying red blood cells. As a result, the blood cannot supply the tissues with sufficient oxygen. Thus, the person feels weak or tired. Other symptoms include dizziness, headaches, rapid heartbeat, and shortness of breath. A lack of iodine can cause goiter, a disease in which the thyroid gland becomes enlarged.

**Other diseases** may result from poor nutritional habits. For example, excessive intake of alcohol causes some forms of liver disease. The risk of osteoporosis (loss of bone tissue) is higher for people—especially women—whose intake of calcium and level of physical activity are low. To prevent osteoporosis, physicians recommend a lifelong combination of regular exercise and a diet with adequate calcium.

**Careers in nutrition**

Nutrition offers a variety of careers in work settings that range from restaurants to research laboratories. Jobs in this field require at least a high school education. Some positions require a two-year associate’s degree or a bachelor’s degree. High school students interested in a career in the field of nutrition should take such science courses as biology and chemistry. College students preparing for a career in nutrition study physiology—the science that deals with how the body works—as well as biochemistry—the science of the chemical reactions that take place in living things. Other required courses include bacteriology and general chemistry. Students interested in careers in medical nutrition learn how diseases affect the body. Students pursuing careers in food service take such courses as food preparation, food purchasing, accounting, and personnel management.

Work as a *dietetic technician* requires an associate’s degree. Dietetic technicians work as members of a food service staff or a health care team, under the supervision of a *registered dietitian*. These technicians supervise support staff, develop nutrition care plans, and provide nutrition counseling for individuals or small groups.

A bachelor’s degree and a period of supervised practice are necessary to become a registered dietitian. Candidates must also pass a registration examination. Many registered dietitians manage food services in schools, nursing homes, and restaurants. Others work in hospitals or clinics, planning special diets for patients who are ill. Some registered dietitians coordinate disease prevention programs for public health organizations or work with community food programs. Others work for corporations, helping to develop food products. A number of registered dietitians offer personal nutrition counseling directly to the public.

People with advanced degrees in nutrition and food science may teach; conduct research projects for government, business, industry, and health care institutions; or hold administrative positions in international food or agricultural programs. These experts may investigate the effect of diet on health or develop improved methods for processing and packaging food. Some create new foods, such as artificial sweeteners, fat substitutes, or foods used in space exploration.

Nutting, Mary Adelaide (1858-1948), was a leader in the development of professional nursing in the United States. She helped establish professional standards in nursing education and the practice of nursing. She developed a model training program that supplemented practical experience in a hospital with practical instruction in nursing principles.

Nutting was born in Quebec, Canada. In 1889, she went to Baltimore to enter the first class of the Johns Hopkins Hospital Training School for Nurses. After graduating in 1891, she served as a head nurse at the school. In 1894, she became the school's principal. Nutting held this position until 1907. That year, she joined the faculty of Teachers College at Columbia University in New York City and became the world's first professor of nursing. Nutting headed the Department of Nursing and Health at the college from 1910 until she retired in 1925.

Kenneth R. Manning

Nyasa, Lake. See Lake Nyasa.

Nyasaland. See Malawi.

Nye, Bill (1850-1896), was a popular American humorist. He became famous for his clever essays and anecdotes (brief stories) on a variety of subjects ranging from the American West to journalism. Nye was also a successful comic lecturer.

Nye was born in Shirley, Maine. His full name was Edgar Wilson Nye. In 1876, Nye moved to Wyoming. He first gained national fame as a columnist for the Laramie Boomerang, a newspaper he founded in 1881. In 1886, Nye moved to New York City and wrote humorous columns for the New York World newspaper. His books include Bill Nye's History of the United States (1894) and Bill Nye's History of England (1896). Both were widely popular for their satirical treatment of the past. Nye and the American poet James Whitcomb Riley wrote Nye and Riley's Railway Guide (1888), a book of poems and witty prose sketches.

David B. Kesterson

Nyerere, nih RAIR ee, Julius Kambarage, kahn BAH rah guh (1922-1999), was president of Tanzania from 1964 until he retired in 1985. Tanzania consists of Tanganyika, a region on the African mainland; and Zanzibar, a nearby island group. Tanganyika and Zanzibar were formerly ruled by the United Kingdom. Nyerere led the movement that resulted in Tanganyika's independence from the United Kingdom in 1961. He became the president of Tanganyika in 1962. He also helped unite Tanganyika and Zanzibar to form Tanzania in 1964, and he became the new country's president. He was first elected president in 1965 and was reelected in 1970, 1975, and 1980. Nyerere retired as president in 1985 and as chairman of the only legal political party in 1990. But he remained a major influence in Tanzania until his death.

As Tanzania's president, Nyerere became a leading spokesman for cooperation among black African nations, and he helped unite Tanzania's many ethnic groups. In 1979, Nyerere sent Tanzanian troops to Uganda, after Uganda had invaded Tanzania. The Tanzanian troops helped overthrow the dictatorship of Idi Amin Dada in Uganda.

Nyerere was born near what is now Musoma, Tanzania. He was educated at various schools in what are now Tanzania and Uganda and at the University of Edinburgh in Scotland. Robert I. Rotberg

See also Tanzania (History).

Nylon is the general term for a group of synthetic products. These products are made from chemicals derived from coal, water, air, petroleum, agricultural by-products, and natural gas. Nylon is one of the most important chemical discoveries. It is a tough elastic substance that can be formed into fibers, bristles, sheets, rods, and tubes. It also can be made in powdered form for use in molding operations.

Nylon fibers and fabrics are noted for their strength, ability to be dyed, low shrinkage, silk-like appearance, and resistance to abrasion, mildew, and insects. They are not harmed by most kinds of oil and grease or by household cleaning fluids. Nylon fabrics dry rapidly because nylon absorbs little water.

Uses. Nylon is used primarily in fibers and fabrics. It was the first synthetic fabric thought to be superior to natural fabrics. Nylon hosiery came on the market in 1939. Since then, many uses have been found for nylon. Carpets, tires, upholstery, dresses, underwear, bathing suits, lace, and parachutes are among the many nylon products. Single threads of nylon are used for fishing line and for bristles in brushes. Surgeons use nylon thread to sew up wounds.

Nylon is also important in the plastics industry. Nylon plastics are noted for their electrical properties, toughness, and resistance to chemicals, fire, and wear. They are used in such products as electrical equipment, gears, tubing, and sporting equipment. Plastic nylon body panels have replaced steel on some automobiles.

How nylon is made. Most nylon produced in the United States is made from two chemical compounds—hexamethylenediamine and adipic acid. Both of these compounds contain carbon and hydrogen. Manufacturers combine the compounds to form hexamethylene diammonium adipate, commonly called nylon salt.

Most nylon factories make the substance by placing a solution of nylon salt in a machine called an autoclave.
The autoclave heats the solution under pressure. The water is removed, and the molecules that make up each of the compounds combine to form large molecules. This process of making large molecules from smaller ones is called polymerization. In some factories, the newly formed nylon comes out of the machine as a plastic ribbon. The ribbon is cooled, hardened, and cut into chips that are used in making a variety of nylon products. See Plastics (How plastics are made).

Nylon fibers are made by forcing molten nylon through tiny holes in a device called a spinneret. In some factories, the molten nylon travels to the spinneret as soon as the polymerization process is completed. Other factories melt nylon chips and pump the melted nylon through the spinneret. The streams of nylon harden into filaments when they strike the air. Then they are wound onto bobbins. From 1 to as many as 2,520 filaments are united into a textile nylon yarn. Nylon fibers are drawn (stretched) after they cool. Some factories draw nylon after it has been spun into yarn. Others spin and draw the yarn in one operation. Drawing involves unwinding the yarn or filaments from one spool and winding them onto another. The winding rate is four or more times as fast as the unwinding rate. The pull between the spools stretches the fibers. Drawing makes the molecules in each filament fall into parallel lines. This process gives the fiber strength and elasticity. After being drawn, the yarn may be twisted a few turns per yard or per meter as it is wound onto spools. It may also be treated to give it a special texture or bulk.

The size of nylon yarn is measured in deniers. A denier is the weight in grams of 9,000 meters (9,843 yards) of the yarn. For example, if 9,000 meters of a nylon yarn weigh 15 grams, the yarn is called 15-denier yarn. History. Wallace H. Carothers, a chemist of the DuPont Company, was a leader in the development of nylon. In the late 1920's, he began to experiment with polymerization. He used a machine called the "molecular still," which made it possible to make longer molecules than had been made before. Carothers found that many of the fibers made from compounds that he polymerized could be pulled out to several times their original length after they were cooled. This pulling process made the fibers much stronger and more elastic. But most compounds that Carothers had made so far melted at a temperature too low to make them practical for textiles that must be ironed. Then, in 1935, he polymerized hexamethylenediamine and adipic acid. The product was called polyhexamethylene adipamide. This material had a melting point of 482°F (250°C), which is satisfactory for textiles. The new fiber was named nylon and was hailed as a great discovery. Later, chemists referred to this original kind of nylon as nylon 66 because both chemicals used in making it had six carbon atoms. Before nylon could be produced for the public, scientists had to find a way to make large amounts of hexamethylenediamine and adipic acid. Researchers at DuPont eventually developed a method for making these chemicals from petroleum, natural gas, and agricultural by-products. Nylon production began in 1938, and the first products made from nylon were introduced in 1939. Most manufacturers in the United States have continued to produce nylon 66. However, other types of nylon have also been developed. Nylon 6, made from a six-carbon chemical called caprolactam, is a major fiber produced in the United States and numerous other countries. A silklike nylon with the trademark Qiana is a popular fiber that is used for clothing.

**Nymph**, in entomology. See Larva. **Nymph**, *nymphl* was a lovely maiden of Greek and Roman mythology who guarded the different realms of nature. *Oreads* watched over the hills and mountains, and *Nereids* kept watch over the Mediterranean Sea. The *naiads* were the nymphs of the rivers, brooks, and streams. The ocean was protected by the *Oceanids*. The *dryads* and *hamadryads* took care of the trees and forests.

Many of the naiads watched over springs that were believed to inspire those who drank their waters. The naiads were thought to have powers to prophesy and to inspire people. The oreads were also known by names that came from the hills or mountains where they lived.

Nymphs were sometimes shy. But at other times, they were passionate lovers. They were generally friendly and kind to mortals but occasionally punished people who offended them. Nymphs are represented with fauns and satyrs in the forest, or playing around the keels of ships. Nymphs lived for a long time, but they were not usually considered immortal.

See also Arethusa.

**Nystagmus**, *nihs TAG muhs*, is an involuntary, rhythmic movement of the eyes. The eyes may move from side to side, up and down, in a circle, or in a combination of these movements. The motions may be rapid or slow, and jerky or smooth. Nystagmus occurs normally, as when a person watches scenery from a moving train. This condition may also be produced by diseases of the eye, the ear, or the brain. Some people are born with nystagmus.

A type of nystagmus known as *miner's nystagmus* is caused by darkness and occurs among miners. *Positional nystagmus* occurs only when the patient's head is placed in an abnormal position or level. *Spontaneous ocular nystagmus* occurs as a result of complete blindness or from defective central vision. *Vertical nystagmus* is an up-and-down movement of the eyes. *Latent nystagmus* occurs when one eye is covered.

**Nzinga Nkuwu**, *ehn ZIHNG ah ehn KOO woo?* (1?1506), was the ruler of the Kongo kingdom in west-central Africa. His subjects believed he was God in human form.

After the first Portuguese trading ships came to Kongo in 1485, Nzinga Nkuwu welcomed trade with Portugal and established a friendly relationship with the Europeans. Portugal sent carpenters, farmers, traders, and other specialists to Kongo. But eventually the Europeans became more interested in developing the slave trade than in aiding the Kongoleses.

After Christian missionaries came to Mbanza, Kongo's capital, Nzinga Nkuwu accepted Christianity as one of Kongo's religions. He was baptized in 1491 and took the name John I, or *Joao*, the name of Portugal's king. However, he gave up Christianity around 1495 because of disputes in his court between supporters and opponents of Christianity. Nzinga Mbemba, Nzinga Nkuwu's son, gained power shortly after Nzinga Nkuwu's death in 1506. A Christian supported by the Portuguese, Nzinga Mbemba took the name Afonso I. Kevin C. MacDonald

The letter **O** is the 15th letter in our alphabet. It also appeared in the alphabet used by the Semites, who once lived in Syria and Palestine. They called the letter 'ayin', their word for eye. For a symbol, they used a stylized picture of an eye. They probably borrowed it from an Egyptian **hieroglyphic** (picture symbol). The Phoenicians borrowed the letter from the Semites. Later, the Greeks borrowed it from the Phoenicians. They called it **omicron**. See Alphabet.

**Uses.** O or o is about the fourth most frequently used letter in books, newspapers, and other printed material in English. In chemistry, O stands for the element oxygen. On maps, the letter is the abbreviation for ocean, as well as Ohio. In modern numbering, it represents the cipher, or zero. In medieval Roman numerals, O represented the number 11 and 0, 11,000. It may also be used as the abbreviation for **old, octavo** (a size of book or method of folding a printed sheet), or **ohm** (a unit used in measuring electrical resistance).

**Pronunciation.** The letter o is a vowel, and has several sounds in English. The main pronunciations are illustrated in the words November (long o), not (short o), off (open o), and out, which scholars consider a diphthong (combination of short o and u sounds). Double o also has several sounds in English. When pronounced as a single vowel, it may have the sounds represented in the words blood, food, and good. There are some words in English in which each o is pronounced separately, as in cooperate. See Pronunciation.

Marianne Cooley

---

**Development of the letter O**

The ancient Egyptians, about 3000 B.C., drew this symbol of an eye.

![Eye symbol](image)

The Semites simplified the Egyptian symbol about 1500 B.C. They named the letter 'ayin', their word for eye.

![Semites symbol](image)

The Phoenicians, about 1000 B.C., drew the letter as a circle.

![Phoenicians symbol](image)

The Greeks borrowed the letter from the Phoenicians about 600 B.C. The Greek letter was called **omicron**.

![Greek symbol](image)

The Romans, about A.D. 114, gave the letter o this graceful shape.

![Roman symbol](image)

**O Canada** is the national anthem of Canada. The Canadian Parliament adopted the song as the national anthem on June 27, 1980. Calixa Lavallée, a Canadian musician, composed the music in 1880. The song has both French and English lyrics. Sir Adolphe Basile Routhier, a Canadian judge, wrote the French lyrics in 1880. Another Canadian judge, Robert Stanley Weir, wrote the English words in 1908. In 1968, some of the wording in the English version was changed. The English lyrics are not a translation of the French lyrics.

The first stanza of the English lyrics is given below, followed by the first stanza of the French lyrics.

O Canada! Our home and native land!
True patriot love in all thy sons command.
With glowing hearts we see thee rise,
The True North strong and free!
From far and wide, O Canada,
We stand on guard for thee.
God keep our land glorious and free!
O Canada, we stand on guard for thee.
O Canada, we stand on guard for thee.
O Canada! Terre de nos âieux,
Ton front est ceint de fleurons glorieux!
Car ton bras sait porter l'épée,
Il sait porter la croix!
Ton histoire est une épopée
Des plus brillants exploits.
Et ta valeur, de foi trempe,
Protégera nos foyers et nos droits,
Protégera nos foyers et nos droits.

Valerie Woodrige Goertzen

**Oahu.** See Hawaii (The islands).

**Oak** is any of a large variety of trees or shrubs that bear acorns. There are more than 600 species of oaks, all of which grow naturally only in the Northern Hemisphere. Most species of oaks are found in tropical and warm regions. Only a few species grow in Canada and other regions that have short summers and long winters. Oaks thrive in forests throughout the continental United States except for Alaska. They also are important in forests of China, Japan, and central and southern Europe.

Oaks vary widely in size and in the way they grow. Some oaks never become taller than small shrubs. Others reach heights of more than 100 feet (30 meters).

Many oaks that grow in warm climates do not lose their leaves in the autumn. They are called evergreens. But most oaks found in regions with cold winters are deciduous—that is, they shed their leaves each autumn. The leaves of many deciduous oaks turn beautiful colors, such as deep red or golden brown, in early autumn.

In the spring, oaks produce small, yellowish-green flowers. The male flowers, which form in dangling clusters called catkins, produce large amounts of pollen. The wind carries the pollen to the female flowers and fertilizes them. Once fertilized, a female flower will become an acorn. The acorn is the fruit of the oak. Acorns vary in length from less than ½ inch (13 millimeters) to more than 2 inches (51 millimeters).

Oaks grow slowly and usually do not bear acorns until they are about 20 years old. But these trees live a long time. Most oaks live for 200 to 400 years.

Oaks are an important source of lumber. Oak wood is heavy, hard, and strong, and it has a beautiful grain. Manufacturers use it for furniture, barrels, and railroad ties. The wood and bark of some oaks contain tannin, a bitter substance used in the preparation of leather. Cork comes from the bark of certain oaks. Acorns are an important source of food for wildlife. In the past, many Indians of North America used acorns for food. Today, oaks are grown as ornamental trees worldwide.

**North American oaks**

More than 300 species of oaks are native to North America. Only about 60 of these grow north of Mexico. Botanists divide oaks into two groups: (1) white oaks and (2) red oaks, sometimes called black oaks. The trees in these two groups differ chiefly in the shape of their leaves and in how long it takes their acorns to mature.

White oaks have lobed leaves, and the tips of the lobes are rounded. Many red oaks also have lobed leaves, but these leaves have pointed tips that end in a hairlike bristle. Some red oaks have unlobed, oval leaves with a sharp tip.

The acorns of white oaks form in the spring, mature during the summer, and are shed in the autumn. The acorns of red oaks need two growing seasons to mature. In general, white oak acorns taste less bitter than do red oak acorns.

White oaks thrive throughout deciduous forests of eastern North America. A species that is named the white oak is especially common. It is easily recognized by its grayish bark, which forms shinglelike plates about 20 to 30 feet (6 to 9 meters) up the trunk. Its leaves usually have seven or nine lobes. The wood of the white oak makes excellent furniture.

Several other white oaks are important members of eastern deciduous forests. The post oak grows in dry soils. It has gray bark and leaves with five lobes. The overcup oak, the swamp chestnut oak, and the swamp white oak are common in swampy areas. The leaves of these three species usually have more than seven lobes. The bur oak ranges from the eastern part of the Great Plains east to New Brunswick and Nova Scotia. This species produces large acorns.

Only a few species of white oaks grow in western North America. The California white oak is common along streams and in moist valleys of California, where it provides shade for livestock. This oak has leaves with 7, 9, or 11 lobes. It bears long, slender acorns. The Oregon white oak is found in river valleys and warm, dry areas from central California to southwestern British Columbia. The leaves of the Oregon white oak resemble those of the California white oak, but it has much plumper acorns. The Oregon white oak also grows as a low shrub along the Oregon coast and in mountainous regions. This oak may be found as high as 4,000 feet (1,200 meters) above sea level.

Red oaks are common in forests of eastern North America. The northern red oak grows from the southern Appalachians north to Ontario and Nova Scotia, and west into Arkansas and Missouri. It is often found along with two other red oak species, the black oak and the scarlet oak. These three species look similar and even experts sometimes confuse them. All three species usually have leaves with seven or nine lobes. But the leaves of black oaks have yellow hairs on the underside. Most scarlet oak leaves have sharply pointed tips and deep notches between the lobes. These oaks are an important source of timber and tannin.
Many red oaks grow only in certain soils or locations. For example, the blackjack oak grows in soils that contain much clay. This oak has pear-shaped leaves with golden hairs on the underside. The turkey oak is found in sandy soils of the Atlantic coastal plain. Its leaves have deeply notched edges.

Evergreens in the red oak group are often called live oaks. The live oak of the Southern States grows in the Gulf and Atlantic coastal plains. Its large, spreading branches are often draped with Spanish moss. In coastal dune areas, these trees grow as shrubs. Live oaks are also common in dry regions of Texas. The California live oak grows on hillsides along the southern California coast, where little rain falls during the summer.

A number of shrubby, evergreen oaks grow in dry areas of California and the Southwest. The California scrub oak is found in regions that have frequent wildfires. Some reach a height of only 3 to 4 feet (0.9 to 1.2 meters). The roots of this oak have many buds. Following a fire, these buds sprout and grow into new shrubs. The shrub live oak is one of several species of shrubby oaks found in the deserts of the Southwestern United States and of Mexico. The shrub live oak is common on mountain slopes.

**Other oaks**

In Britain and northern Europe, two common deciduous trees are the English oak and the sessile oak, also called the durmast oak. These two species of oaks are easy to tell apart by the way their acorns grow. The acorns of English oaks grow on long stalks. The acorns of sessile oaks attach directly to twigs. Both of these oaks may grow to a height of more than 110 feet (34 meters). Some have lived more than 800 years. The wood of these oaks is used for beams and shipbuilding.

Several deciduous species of oaks also grow in the mountain forests of southern Europe. These include the Hungarian oak and the Pyrenean oak. Both are used for ornament and shade in gardens worldwide.

Live oaks grow in regions of southern Europe that have mild winters. The holm oak looks much like the live oaks of the Southwestern United States. It is an important timber tree and an excellent source of charcoal. The holm oak is grown in parks and along roads throughout the world. The cork oak is found chiefly in Spain and Portugal. Cork comes from the bark of this tree.

Many oak species grow in the forests of central and eastern Asia. The Lebanon oak is common in mountainous regions of the Middle East. The Mongolian oak is an important timber tree in eastern Asia, including Japan. Both of these species can be found in parks and gardens in the United States.

**Scientific classification.** Oaks are in the beech family, Fagaceae, and make up the genus Quercus. The scientific name for the white oak is Quercus alba, the northern red oak is Q. rubra, the live oak of the Southern States is Q. virginiana, and the English oak is Q. robur. —Norman L. Christensen, Jr.

other nonnuclear sources of energy. In addition, scientists study how the use of various forms of energy affects the environment and human health.

Oak Ridge National Laboratory was established in 1943 as part of the World War II Manhattan Project to build the atomic bomb. The main objective of the laboratory's wartime activities was to develop a process for separating plutonium, an explosive material used in atomic bombs, from uranium. Today, the University of Tennessee and Battelle Memorial Institute, a research and development organization, operate the laboratory under contract with the U.S. Department of Energy.

Toni Grayson Joseph

Oakland (pop. 399,484; met. area pop. 2,392,557) is one of the busiest shipping centers in California. The city lies on the eastern shore of San Francisco Bay, an inlet of the Pacific Ocean. Oakland is 3 miles (4.8 kilometers) across the bay from San Francisco (see California [political map]). Oakland was founded after the discovery of gold in California in 1848. The city was named for the oak trees that grew on its hills.

Description. Oakland, the seat of Alameda County, covers about 54 square miles (140 square kilometers). The Oakland metropolitan area covers 1,624 square miles (4,206 square kilometers). Lake Merritt lies in the heart of downtown Oakland. The Lake Merritt Nature Center and Wildlife Refuge, the oldest wildlife refuge in North America, opened in 1870. Jack London Square includes the bay waterfront that was visited frequently by the author for whom it was named.

Attractions in the city include the Oakland Museum of California, the Chabot Space and Science Center, the Oakland East Bay Symphony, and the Oakland Ballet. The African American Museum and Library at Oakland includes letters, diaries, and photographs that share the experiences of blacks in California. Colleges in Oakland include California College of Arts and Crafts, Holy Names College, Mills College, and Patten College. Oakland is home to the Oakland Athletics baseball team of the American League, the Oakland Raiders of the National Football League, and the Golden State Warriors of the National Basketball Association.

Economy. Oakland is a major transportation center. The Port of Oakland is one of the world's busiest ports for container ships. The western terminals of several freight railroad systems are in Oakland. Passenger trains link Oakland with other cities in the United States. The Bay Area Rapid Transit system (BART), a regional rail system, has its headquarters in the city. Air travelers use Oakland International Airport.

A majority of Oakland's workers are employed in service industries. Important economic activities in the city include business and health care services, food processing, and transportation.

Government and history. Oakland has a council-manager form of government. The voters elect a mayor and eight council members to four-year terms. The council appoints a city manager to carry out its policies.

Ohlone, also called Costanoan, Indians lived in what is now Oakland before European settlers arrived. In the 1770's, Spanish explorers and missionaries became the first Europeans to reach the region. In 1820, Luis María Peralta, a Spanish soldier, received a land grant that included most of the area that is now Alameda County. By 1849, merchants, loggers, and gold seekers had begun to settle the region. Oakland was incorporated as a town in 1852 and as a city in 1854.

Oakland's population grew rapidly after it was chosen as the western terminus (end) of the first transcontinental railroad in 1869. About 65,000 people settled in the city in 1906 after fleeing the San Francisco earthquake. Industrial expansion took place through the 1920's. Many automobile manufacturers and food processing and steel companies were established in the city. Oakland became a major port and shipbuilding center during World War II (1939-1945).

In the 1970's, the city began several urban renewal projects in the downtown area. Construction on Oakland City Center, a complex of office buildings and retail stores, was completed in 1990. Preservation Park, a showplace of historic homes that were moved from other parts of the city, opened in 1991.

In October 1989, a strong earthquake struck Oakland and the surrounding area. As a result of the earthquake, a portion of the upper level of the city's double-decked Nimitz Freeway, or Interstate Highway 880, collapsed onto the lower level. The earthquake caused 43 deaths and extensive property damage in Alameda County. In

Oakland, California, lies on the eastern shore of San Francisco Bay, 3 miles (4.8 kilometers) across the bay from San Francisco. Lake Merritt, foreground, is a large saltwater lake in the heart of downtown Oakland.
October 1991, a brush fire in Oakland killed 25 people and caused much property damage.

Redevelopment programs continued into the 2000's. In the late 1990's, businesses and residents began relocating from an overcrowded San Francisco to Oakland.

Betty Marvin

Oakley, Annie (1860-1926), was a famous American sharpshooter who starred in Buffalo Bill's Wild West show for over 16 years. She was assisted by her husband, Frank Butler, and part of her act was to shoot a dime out of his hand or a cigarette out of his mouth. Oakley also could hit a playing card thrown into the air 90 feet (27 meters) away from her. She gained world-wide fame on European tours for such daring deeds as shooting a cigarette held in the mouth of the German Crown Prince Wilhelm.

Annie Oakley was born Phoebe Ann Moses in Darke County, Ohio. She learned to shoot at the age of 8 and helped support her family by killing game for a hotel in Cincinnati. At age 15, she defeated Butler, a professional marksman, in a shooting exhibition. In 1876, she and Butler married. She then adopted the stage name Annie Oakley and took part in shooting exhibitions.

Oakley was only 5 feet (150 centimeters) tall. She was called "Little Sure Shot" by the famous Sioux Indian chief Sitting Bull, who toured briefly with Buffalo Bill's Wild West show. Oakley joined the show in 1885, and Butler became her manager. In 1901, she was injured in a train accident and resigned from the show. She joined a theatrical group and starred in The Western Girl (1902). During World War I (1914-1918), she gave shooting exhibitions and instruction to American soldiers.

The popular musical comedy Annie Get Your Gun (1946), which has songs by composer Irving Berlin, is loosely based on Oakley's life. It portrays her as an outspoken tomboy. In reality, she was a quiet, simple person who did needlepoint in her free time.

Oared. See Rowing.

Oarfish is the longest bony fish. It normally measures 16 to 35 feet (5 to 11 meters) long. However, people have reported seeing oarfish more than 55 feet (17 meters) in length. The fish live in temperate (mild) and warm seas, normally at depths of 1,000 to 2,000 feet (300 to 610 meters). They have flat-sided, silvery bodies with bright red fins. On the underside of an adult's body, two long pelvic fins end in blade-shaped swellings. These fins resemble the oars of a rowboat, giving the fish its name. Oarfish have no teeth and feed chiefly on tiny shrimp-like creatures called krill. The fish swim in a snakelike motion. Occasionally, they travel to the ocean surface. Because of their size and appearance, oarfish probably inspired many "sea serpent" myths. Scientists know little about oarfish because the fish live in deep water and have never been kept in aquariums. John E. McCosker

See also Fish (picture: Fish of the deep ocean).

Scientific classification. The oarfish is in the family Regaleidae. It is Regalecus glesne.

OAS. See Organization of American States; France (France under de Gaulle).

Oasis is a fertile, vegetated area in a desert where underground water comes close enough to the surface for

---

Annie Oakley became famous as one of the world's most accurate shots with pistol, rifle, and shotgun.
On an artificially created oasis in southern California, above, jojoba plants are grown for their seed oil.

wells and springs to exist. Water that occurs at an oasis originally fell as rain or snow in distant mountains or hills. After seeping into the ground, the water slowly filters through the underground rocks toward low places in the desert. It then reappears at the surface to form springs or is shallow enough to be found in wells. Fertilized, vegetated areas along permanent streams in deserts are sometimes also called oases.

Soil in desert regions is generally fertile but lacks the moisture to encourage plant growth. Because oases have water, almost all of them are areas of farming and settlement. Some oases are small and can support only a few people, but others are large enough to support millions of people.

Oates, oats. Joyce Carol (1938- ), is an American author. She gives most of her novels and short stories a nightmarish quality and emphasizes sex and violence. However, her most significant subjects are society and the insanity it generates. At the core of her work is a moral vision. Oates has written about 40 books. Some critics argue she would profit from polishing her fiction, but most agree that her pictures of society are accurate.

Often Oates's characters are mentally ill. For example, in Expensive People (1968), a teen-ager has difficulty distinguishing reality from fantasy and confesses to his mother's murder, though he may not have committed the crime. The hero of Wonderland (1971) and the heroine of Do with Me What You Will (1973) have mentally ill fathers. Oates's novella Black Water (1992) portrays actions of a politician who belongs to a powerful dynasty and reveals himself to be violent and a victimizer of the narrator.

Oates's stories have been collected in By the North Gate (1963), The Wheel of Love (1970), Last Days (1984), Raven's Wing (1986), Heat (1991), and Will You Always Love Me? (1996). Her Twelve Plays was published in 1991. She has also written scholarly essays and poetry.

She was born in Lockport, New York.

Victor A. Kramer

Oath is a pledge or promise. The judicial oath is probably the most common form. It is used in a court of law, at a deposition, or before a notary public or other judicial officer (see Deposition; Notary public). A witness taking a judicial oath swears that all of his or her statements are true. Often the person must lay a hand on the Bible while taking the oath. This gesture means that the person is making a declaration through God. A person swearing to the truth of an affidavit may be given the following oath: "You do solemnly swear that the contents of this affidavit by you subscribed are true, so help you God."

A person who takes an oath in court and then makes a dishonest statement while under oath is guilty of perjury, a crime punishable by a fine or jail sentence.

All of us are familiar with oaths in everyday life. For example, a person who promises to give up a bad habit is said to "take an oath." This kind of oath is called extra-judicial because it has no force in a court of law. Oaths taken to show good faith are also extra-judicial.

Affirmation. Some religious groups, such as the Quakers, do not approve of swearing by an oath. They believe in the Bible's command "Swear not at all." When members of such groups testify in court, they take an affirmation instead of an oath. The affirmation binds them to the truth as strongly as an oath would. If a person violates an affirmation, he or she becomes guilty of perjury.

Oath of office. Many officials must take a pledge when they enter a public office. This oath of office is a promise to carry out the duties of the office honestly and faithfully. According to the Constitution of the United States, the nation's president must take the following oath at the inauguration: "I do solemnly swear (or affirm) that I will faithfully execute the Office of the President of the United States, and will to the best of my ability, preserve, protect and defend the Constitution of the United States."

All United States officers lower in rank than the president take oaths much like the one above. An officer taking over a state public office promises to protect the state constitution as well as the U.S. Constitution.

In Canada, many government officials take a pledge upon entering public office. Officials appointed to the federal Senate or elected to the House of Commons, and members of the legislative bodies of the provinces, take the following oath: "I do swear (or affirm) that I will faithfully execute the Office of the President of the United States, and will to the best of my ability, preserve, protect and defend the Constitution of the United States."

Military oaths are taken by people who enter the armed forces. Before a person enters the service, he or she must take the following oath: "I do solemnly swear (or affirm) that I will support and defend the Constitution of the United States against all enemies, foreign and domestic; that I will bear true faith and allegiance to the same; and that I will obey the orders of the President of the United States and the orders of the officers appointed over me, according to regulations and the Uniform Code of Military Justice. So help me God." Members of the armed forces of Canada, the United Kingdom, and other countries take a similar oath.

Oatmeal is a food product prepared from oats. It is commonly eaten as a cooked breakfast cereal. Oatmeal is made by removing the outer husk of the oat kernel. The groats, or inner portion of the kernel, is scoured to remove some of the outer skin. Then it is partially cooked by steaming, and rolled to form flakes.

Oatmeal is a good source of B vitamins and iron. One cup (240 grams) of cooked oatmeal contains about 23 grams of carbohydrates, 5 grams of protein, and 2 grams of fat. One cup is made up of about 85 percent water and has 130 calories.

Oats are an important grain crop. Farmers grow them mainly to feed livestock, but oats also provide nourishing food for many people. The seeds of oat plants are processed and used in such foods as oatmeal, oatcakes, cookies, and ready-to-eat breakfast cereals.

Oats are a cereal grain and belong to the same family of plants as wheat, rice, corn, and barley. Oats have a higher food value than any other cereal grain. They are rich in starch and high-quality protein, and they provide a good source of Vitamin B. Some nutritionists believe that the addition of oat bran (the seed covering of oats) to the diet helps reduce cholesterol.

About 60 percent of the oats grown in the United States are used as feed for livestock. Oats are the best grain to feed horses. Many farmers use the straw from oats as bedding for their livestock.

Russia is, by far, the leading oat-growing country. The world's annual production of oats totals about 33 million tons (30 million metric tons).

The oat plant has a stem that grows from 2 to 4 feet (60 to 120 centimeters) high. The stem ends in a head called a panicle, which consists of many small branches. Each branch ends in a single spikelet (flower cluster). The majority of oat plants have from 40 to 50 spikelets. Most spikelets contain two seeds, each enclosed by a husk called the hull. The hull must be removed before the seeds can be processed into oatmeal or other food products. The oat seed, called a groat, is usually the same color as the hull. Different varieties of oat seeds

---

**Oatmeal**

The food value of oatmeal makes it a nourishing breakfast cereal. One cup of oatmeal has about 130 calories.

---

**Oat plants** have heads called panicles. Each panicle has many flower clusters called spikelets, which contain the seeds. Each seed is enclosed by a hull.

---

**Planting oats.** Many farmers plant oats with a machine called a grain drill. Planting takes place in early spring in most regions.

---

**Harvesting oats.** a farmer may use a combine. This machine cuts down the stalks and separates the grain from them.
may be white, yellow, red, gray, or black.

The chief kinds of cultivated oats include common oats, red oats, side oats, and hull-less oats. Common oats are the type most widely grown in the United States. Red oats have reddish seeds. Side oats have all their branches on one side of the stalk. Hull-less oats, unlike the other types, have loose husks that separate from the seeds during harvesting.

**Growing oats.** Oats can be grown in a variety of climates and soils. But they grow especially well in areas that have a cool, moist climate and fertile soil. Farmers may add fertilizer to poor soil to increase the yield.

Farmers grow two types of oats, spring oats and winter oats. Spring oats are planted in early spring and harvested in summer. The date of planting and harvesting depends on the climate of the area. Spring oats account for more than 85 percent of the U.S. oat crop. Winter oats are planted in fall and harvested the next summer. They start growing before the weather turns cold. Growth stops in the winter and begins again in spring. Winter oats are not as hardy as other winter grains, and so they are grown chiefly in areas with mild winters.

Oats are planted either by simply scattering the seeds over the field or by sowing the seeds with a grain drill. This machine drops the seeds into furrows and covers them with soil. The seeds are planted in rows about 6 to 7 inches (15 to 18 centimeters) apart and covered with about 2 inches (5 centimeters) of soil. Most farmers use sowing rates of 60 to 90 pounds per acre (65 to 100 kilograms per hectare) of land.

**Harvesting oats.** Oats are harvested after the plants become dry and yellow and the seeds harden. The grain should not contain more than 12 to 14 percent moisture when harvested. Farmers can take samples of the seed to a grain elevator for a moisture test.

Some oats are grown for hay or silage. Silage consists of chopped plant stalks, which are stored in a silo and used to feed livestock during the winter. Oats grown for hay or silage are harvested while the plants are still green and the seeds are soft.

Most farmers harvest oats with a machine called a combine, which cuts the stalks and separates the grain from the chaff (stiff, strawlike bits surrounding the grain). Before oat grain is made into human food products, the hulls are removed from the seeds at processing plants. Hulls are not removed from grain used as livestock feed. The average yield of oats in the world is about 1,500 pounds per acre (1,700 kilograms per hectare). The United States average is about 1,800 pounds per acre (2,000 kilograms per hectare).

**Diseases and insect pests.** Various diseases sometimes attack oats and sharply reduce the yield. They include smuts, rusts, septoria, and barley yellow dwarf. Oat crops can also be damaged by such insects as aphids, army worms, cutworms, cereal leaf beetles, and grasshoppers. Aphids are especially troublesome because they spread the barley yellow dwarf disease.

Some farmers use chemical sprays to control diseases and insects. But the best protection comes from planting resistant varieties of oats. Researchers continually develop new varieties that are more resistant to diseases and insects. The new varieties also produce higher yields and better grain. See Smut; Rust; Aphid; Army worm; Cutworm. 

**Scientific classification.** Oats belong to the grass family, Poaceae or Gramineae, and to the genus *Avena*. Common oats belong to the species *A. sativa*.

for handicrafts. The city's economy relies largely on tourism and the sale of cattle, dairy products, and hardwoods. The ruins of two ancient Indian cities, Mitla and Monte Albán, lie near Oaxaca. Some historians believe the Mixtec founded Oaxaca in 1486. But the Zapotec and the Mixtec Indians had lived in the area since the time of the early Christians. The people of colonial Oaxaca produced impressive architecture.

Roderic A. Camp

See also Mixtec Indians; Zapotec Indians.

Ob River, ahb, awb, or oha, is one of the chief rivers of Russia in Asia. It rises in the Altai Mountains of western Siberia and flows northwest for 2,268 miles (3,650 kilometers) before it empties into the Kara Sea through the Gulf of Ob (Obskaya Guba). For location, see Russia (terrain map). The river drains about 1.130,000 square miles (2,930,000 square kilometers).

The navigable waterways of the Ob and its tributaries total about 19,000 miles (30,600 kilometers). The lower part of the river is 2 to 4 miles (3 to 6 kilometers) wide, while the estuary averages about 35 miles (55 kilometers) in width. It is blocked with ice from October to June. In summer, the Ob River is an important water route for shipping grain, dairy products, livestock, wool, and meat. Most of these products move to the railways for shipment to the western part of Russia, but some are exported by way of the Arctic Ocean.

Craig ZumBrunnen

Obadiah, on buh D' uh, Book of, is a book of the Hebrew Bible, or Old Testament, named for an Israelite prophet. The book is the shortest in the Bible, consisting of 21 verses. It was probably composed after the destruction of Jerusalem in 587 or 586 B.C.

The Book of Obadiah has three sections. They deal with the destruction of Edom (verses 1-9), the misdeeds of Edom against Israel (10-14), and the restoration of Israel at the expense of other nations (15-21). Verses 1-9 closely parallel the Book of Jeremiah (49:7-21), but Obadiah appears to preserve the original form of this prophesy. The author's familiarity with prophetic themes, such as "The Day of the Lord" (15-21), places him in the mainstream of late biblical prophecy.

Eric M. Meyers

See also Bible (Books of the Hebrew Bible).

Obelisk, AHB uh lihsk, is a great, upright, four-sided stone pillar. The sides slope slightly so that the top is smaller than the base. The top is shaped like a pyramid and ends in a point. The Washington Monument in Washington, D.C., is a good example of an obelisk.

Ancient Egyptians erected huge obelisks that were cut from single blocks of granite. Most obelisks had inscriptions in hieroglyphics (picture writing). They were often erected in pairs at entrances to temples. Two obelisks, now known as Cleopatra's Needles, were originally at Heliopolis, Egypt. In the 1800s, one was taken to New York City, and the other to London (see Cleopatra's Needles). An obelisk from the temple of Luxor, Egypt, is now in Paris' Place de la Concorde.

Obelisks were cut right at the quarry. The ancient Egyptians first made a horizontal, three-sided form by cutting deep trenches all around the form. Then they split away the fourth side either by inserting copper or wooden wedges, or by pounding through the underside with balls of diorite, a hard rock. Finally they polished the obelisk. Still unexplained is exactly how they raised the huge stone pillar to an upright position at its final site.

Oberammergau, on buh AR nuhr cow (pop. 4,664), is a Bavarian village 45 miles (72 kilometers) southwest of Munich in southern Germany (see Germany [political map]). It is famous for its performances of the Passion Play, which normally take place every 10 years. This pageant, which attracts thousands of tourists, portrays the suffering and death of Jesus. Residents perform all the parts. The play was first performed in 1634 (see Passion Play).

Oberammergau lies in a valley at the foothills of the Bavarian Alps. Bible scenes cover the outside walls of many of the village's buildings. Some of these painted scenes date back to the 1600s. Many people of Oberammergau produce fine wood carvings. Much of the village's income comes from the tourist trade and the sale of carvings.

John W. Boyer

Oberlin College, OH buhr lihn, is a privately controlled, coeducational liberal arts school at Oberlin, Ohio. It was the first coeducational college in the United States. Oberlin College has a college of arts and sciences and a conservatory of music. Courses lead to bachelor's and a few master's degrees. Oberlin was founded in 1833. In 1841, it became the first United States school to award college degrees to women. See also Coeducation.

Oberammergau residents perform the town's famous Passion Play, which portrays the suffering and death of Jesus. The play was first staged in 1634 and is normally presented every 10 years.
Obesity. See Weight control.

**Oboe** is the smallest and highest-pitched of the double-reed woodwinds. The name comes from two French words: *haut*, meaning *high*, and *bois*, meaning *wood*. The oboe is about 21 inches (53 centimeters) long. It was developed in the 1600s, probably by two French musicians, Jean Hotteterre and André Philidor.

The range of the oboe is almost three octaves. The tone is produced by means of a small double reed. Predecessors of the oboe, called *shawms*, had a raucous, penetrating sound. But today the oboe is known for its smooth and beautiful tone.

The oboe is important in symphony orchestras, concert bands, and small ensembles. Composers who wrote works for the oboe include Ludwig van Beethoven, George Frideric Handel, and Wolfgang Amadeus Mozart. The English horn is an alto oboe, a fifth lower in pitch than the oboe.

**Obote, oh BOH tee, Apollo Milton, uh PAHL oh** (1926- ), served as president of Uganda from 1966 until 1971 and from 1980 until 1985. Obote was born in the Lango district of Uganda. In 1958, he was elected to the Ugandan legislature. In 1960, Obote became leader of the Uganda People's Congress, a new political party he had helped create. He led Uganda, then a British protectorate, to independence in 1962. He then served as the first prime minister of the nation. In 1966, Obote seized full control of the government and declared himself president. The people elected him president in 1967.

As president, Obote abolished the country's separate local kingdoms and ruled with absolute power. He put industry under government control. A military revolt overthrew him in 1971, and he went into exile. Idi Amin Dada, who led the revolt, ruled Uganda until 1979. In 1980, Obote returned to Uganda and was elected president. Military leaders again overthrew him in 1985, and he went into exile. Robert I. Rotberg

See also Uganda (History).

**Obregón, oh bray GAHN, Álvaro, AHL vah roh** (1880-1928), was president of Mexico from 1920 to 1924. He succeeded Venustiano Carranza as president, after Carranza was killed in a revolt led by Obregón. As president, Obregón distributed some land among the peasants, built many schools, and supported a strong labor union movement. He was reelected president in 1928 but was assassinated before he could take office.

Obregón was born in the municipal district of Navojoa in Sonora. In 1912, he raised a force of Yaqui Indians and defended President Francisco Madero during a revolution against the government. In 1913, Victoriano Huerta murdered Madero and seized the presidency. That same year, Obregón joined Venustiano Carranza in a revolt against Huerta and, in 1914, fought Pancho Villa to help Carranza become acting chief of Mexico. Obregón later opposed Carranza after Carranza refused to support his efforts to become president. W. Dirk Raat

See also Mexico (Economic and social changes); Carranza, Venustiano; Villa, Pancho (with picture).

**O'Brien, Lawrence Francis** (1917-1990), served as postmaster general of the United States from 1965 to 1968. He helped modernize the postal system and turn the Post Office Department into a semiprivate corporation. From 1961 to 1965, he was a special assistant in charge of congressional relations to Presidents John F. Kennedy and Lyndon B. Johnson. O'Brien served as chairman of the Democratic National Committee in 1968 and 1969, and from 1970 to 1972. O'Brien served as commissioner of the National Basketball Association (NBA) from 1975 to 1984. He was born in Springfield, Massachusetts.

James I. Lengle.

**O'Brien, Robert C.** (1918-1973), was the pen name of Robert Leslie Conly, an American author of children's books. O'Brien won the 1972 Newbery Medal for *Mrs. Frisby and the Rats of NIMH* (1971). This novel tells about a widowed mouse who willingly faces many dangers to save her invalid son. She receives aid from superintelligent rats who have escaped from a laboratory at the National Institute of Mental Health (NIMH).

**Obscenity and pornography** are terms used to designate written, recorded, or pictorial material—including motion pictures—that many people consider indecent and thus find offensive. The term *obscenity* can also refer to any language or behavior believed to corrupt public morals. The term *pornography* refers chiefly to written or sexually explicit pictorial material intended primarily to cause sexual stimulation. Some people use the term to refer to written or pictorial material that glorifies violence against women or degrades women. In many cases, however, the terms *obscenity* and *pornography* are used interchangeably.

In the United States, most states and cities have laws against publishing, distributing, or selling obscene
materials. There are also federal laws against the interstate sale and distribution of such material and against the presentation of obscene material on radio or television. But these laws have been hard to enforce, in part because it is difficult to determine what is obscene according to the law.

The nature of obscenity and pornography and the laws governing them have been a continuing source of controversy. Some people are convinced that the distribution of pornographic material corrupts public morality. Others focus on the extent to which some printed or photographic material portrays violence against women—and the degradation of women—as appropriate behavior. From this perspective, the problem is not in the portrayal of sex, but in the portrayal of women as existing for the sexual satisfaction of men. Others believe existing antiobscenity laws and proposed antipornography laws violate the rights of free speech and press guaranteed by the First Amendment to the U.S. Constitution.

Congress passed the first federal law against obscenity as part of the Tariff Act of 1842. This law made it illegal to bring what it called "indecent and obscene" material into the country. The Comstock Law, passed in 1873, prohibited the mailing of indecent materials.

In 1957, in the case of Roth v. the United States, the Supreme Court ruled that freedom of speech and the press—as guaranteed by the First Amendment—restricted prosecution to only those materials that a court had determined to be legally obscene. But the Supreme Court provided only loose guidelines for the definition of legally obscene material.

In 1973, in the case of Miller v. California, the Supreme Court held that material could be considered legally obscene only if (1) the average person, applying contemporary community standards, would find that the material, taken as a whole, appeals to the prurient (sexually arousing) interest; (2) the material shows, in a clearly offensive way, sexual conduct specifically described in the applicable law; and (3) the material lacks serious literary, artistic, political, or scientific value, when evaluated in accordance with national standards. In 1974, in Jenkins v. Georgia, the Supreme Court unanimously determined that local standards play a very limited role in the determination of what is to be considered obscene. Today, as a result of Jenkins v. Georgia, Miller v. California, and other cases, obscenity prosecutions are rare.

A national Commission on Obscenity and Pornography reported in 1970 that it found no reliable evidence that pornography caused crime among adults or delinquency among young people. The commission recommended repeal of all laws prohibiting the sale of pornography to consenting adults. But it also recommended that each state adopt laws against the sale of obscene pictorial material to young people. In 1986, however, the Attorney General's Commission on Pornography determined that a relationship existed between sexually violent or degrading materials and the amount of sexual violence in society. It also recommended increased prosecution of cases dealing with child pornography—that is, pornographic materials that involve photographs of children.

In other countries. Many nations have antiobscenity laws. In some, including Ireland and Italy, such laws are strictly enforced. In Canada, antiobscenity groups have fought for years for stricter laws and stricter enforcement. Many members of these groups seek recognition of the harm resulting from materials that endorse sexual violence against women. But some nations have repealed their obscenity laws. In the late 1960's, for example, Denmark dropped all legal barriers against pornography for adults. Frederick Schauer

Additional resources

Observatory is a research institution where astronomers study planets, stars, galaxies, and other celestial objects. An observatory has at least one telescope or other kind of observation device. Most such devices are housed in structures built on the ground, but observation equipment is also used underground, in airplanes, and in satellites. Certain satellites that house telescopes are also known as observatories.

The term observatory can also refer to certain ancient structures that people probably used to keep track of important days of the year. One such structure, Stonehenge, in Wiltshire, England, consists of large stone slabs set in the ground. People may have used Stonehenge to determine, for example, when summer began. At the beginning of summer, the sun would rise above an imaginary line between a certain pair of slabs.

Observatories with telescopes
Where observatories are built. Earth's atmosphere influences the selection of sites for telescopes. Telescopes work with visible light and other forms of electromagnetic radiation sent out by objects in space. The radiation travels in waves, and the forms differ in wavelength, distance between successive wave crests. The forms of electromagnetic radiation are—from the shortest to the longest wavelength—gamma rays, X rays, ultraviolet rays, visible light, infrared rays, and radio waves.

The atmosphere blocks gamma rays and X rays as well as certain wavelengths of infrared and ultraviolet rays. Telescopes built to work with such radiation must therefore operate aboard satellites. The atmosphere also partially blocks other infrared and ultraviolet wavelengths. However, telescopes on high mountains can detect some infrared and ultraviolet rays. Telescopes in aircraft that fly at high altitudes can observe more infrared wavelengths. To "see" the remaining infrared and ultraviolet wavelengths, a telescope must operate in space.

Visible light and radio waves pass readily through the atmosphere. So optical telescopes—those that detect visible light—and radio telescopes can be on the ground.

Ground-based observatories. Optical telescopes are built on mountaintops or high plains to avoid air pollution, illumination from city lights, and the distorting effect of the atmosphere. The distorting effect, which also causes the stars to twinkle, blurs images of stars and
Mauna Kea, on the island of Hawaii, has some of the largest optical telescopes in the world. The two spherical structures in the left center of this photo are the W. M. Keck Observatory of the United States. In the cylindrical building beside them is the Subaru telescope of Japan.

other heavenly objects. A high-altitude location will also more likely offer a large percentage of clear nights because it is above low-lying clouds.

Radio telescopes must be shielded from radio waves that are used for communications. So some radio observatories are built in valleys so that the surrounding hills shield them. Others are on mountaintops or high plains. One of the chief mountain sites is Mauna Kea, a volcano that rises 13,796 feet (4,205 meters) above sea level on the island of Hawaii. Major optical telescopes on Mauna Kea include Keck I and Keck II, operated by a partnership of the University of California and the California Institute of Technology (Caltech); and Subaru, operated by Japan’s National Astronomical Observatory.

A radio telescope known as the Robert C. Byrd Green Bank Telescope (GBT) is in a valley in Green Bank, West Virginia. A group of 27 radio telescopes called the Very Large Array (VLA) stands on a high plain near Socorro, New Mexico. The National Radio Astronomy Observatory of the United States operates the GBT and the VLA.

Airborne observatories. From 1975 to 1995, the Gerard P. Kuiper Airborne Observatory (KAO) made observations at infrared wavelengths. The KAO was a modified C-141 cargo plane equipped with a telescope whose light-gathering mirror was 36 inches (91 centimeters) across. The craft flew at altitudes as high as 45,000 feet (13.7 kilometers). The National Aeronautics and Space Administration (NASA) of the United States operated the KAO.

Satellite observatories. The best-known satellite observatory is the Hubble Space Telescope, launched in 1990 to observe infrared, visible, and ultraviolet radiation. It was the first of NASA’s four “Great Observatories” to go into orbit. The second was the Compton Gamma Ray Observatory, which circled Earth from 1991 to 2000. The third is the Chandra X-ray Observatory, launched in 1999. The last of the four, the Space Infrared Telescope Facility, was due to be launched in 2003.

How observatories are operated. The staff of a ground-based, telescopic observatory consists of astronomers, engineers, technicians, telescope operators, computer programmers, optics experts, and administrators. But astronomers who are not on the staff do most of the research.

Teams of astronomers share time on the major telescopes. Teams wishing to use a telescope must submit research proposals to a special committee. The committee approves certain proposals and divides up the time that is available on the telescope. In general, a given team will have limited access—often only a few nights of use a year.

Large ground-based telescopes are so complex that a telescope operator is usually present at the observatory. However, an astronomer does not necessarily have to go to the observatory to use one of its telescopes—the astronomer can work via computer links. Computer-controlled light detectors mounted on the telescope convert the results of the observations to electric signals, so the data can be transferred over the links. Orbiting observatories are operated by radio commands sent from a control center on the ground.

Other kinds of observatories

Neutrino observatories detect subatomic particles called neutrinos that come from space. Neutrinos rarely interact with other kinds of matter, so a neutrino observatory must use a huge quantity of matter as a neutrino target. Neutrino observatories are built beneath Earth’s surface because large numbers of other particles would interact with a target on the surface.

The target at the Sudbury Neutrino Observatory (SNO) in Greater Sudbury, Ontario, is 1,100 tons (1,000 metric tons) of heavy water held in an underground tank. Heavy water is slightly heavier than ordinary water because it contains deuterium, a hydrogen atom that weighs more than the ordinary hydrogen atom. SNO is operated by Sudbury Neutrino Observatory Institute, an organization with representatives from Canada, the United Kingdom, and the United States.

Gravitational observatories. Astronomers are building ground-based observatories to detect gravitational waves. According to the general theory of relativi-
ty announced by the German-born American physicist Albert Einstein in 1915, gravity can travel in waves. However, such waves have not yet been directly detected.

To detect them directly, the observatories will use objects that are large enough to be measurably affected by them. The Laser Interferometer Gravitational-Wave Observatory (LIGO) will have three detectors, two in Hanford, Washington, and one in Livingston, Louisiana. Each detector will use two metal tubes, each 2.5 miles (4 kilometers) long. When a wave passes through the tubes, it will change their lengths. A laser device will detect the changes. Caltech and the Massachusetts Institute of Technology will operate LIGO.

Obsessive-compulsive disorder is a common mental illness in which people feel burdened by unwanted thoughts or forced to repeat troublesome actions. Unwanted thoughts, called obsessions, often include unreasonable fear of dirt or germs. Another common obsession involves fear of losing control and hurting oneself or others. Many patients also feel a need to perform repeated actions, called compulsions, to prevent harmful events. Some wash their hands excessively to avoid infection. Unreasonable repetition of everyday routines—for example, checking that faucets or stoves are turned off—is also common.

Most people have certain routines and habits that they find comforting. For example, a person may like to get dressed or prepare for bed in a certain way. But most people can change their routines when the need arises. People with obsessive-compulsive disorder feel trapped and unable to change, even though they know that their obsessions and compulsions are unrealistic.

Many experts believe that obsessive-compulsive disorder involves an imbalance in serotonin, one of the brain’s most important messenger chemicals. Doctors may treat the disorder with medicines that correct serotonin levels. People may also be helped by behavior therapy, which teaches patients ways to resist their unreasonable thoughts and actions.

Donald W. Black

Obsidian, ahb SIHD ee uhN, is a natural glass formed when hot lava flows onto the surface of the earth and cools quickly. Obsidian has the same chemical composition as granite, but it is quenched to make glass rather than cooled slowly to form crystals. Most obsidian is black, or black with red bands. It is brittle. Indians used it to make arrowheads and knives. See also Granite; Igneous rock.

Marilyn M. Lindstrom

Obstetrics and gynecology, ahb STEHT uhk, is a branch of medicine that deals with women’s health. Obstetrics is concerned with pregnancy, childbirth, and the six-week period following delivery. Doctors who practice obstetrics are called obstetricians. Gynecology deals with diseases of the female reproductive organs. Doctors who practice gynecology are called gynecologists.

During a woman’s pregnancy, an obstetrician is responsible for the health of both the mother and the fetus (unborn child). The obstetrician must take special care to avoid harming the fetus when treating diseases in the mother. During childbirth, the obstetrician helps deliver the baby. Thereafter, the obstetrician examines the mother periodically to make sure she recovers from the changes that occurred in her body during pregnancy.

A gynecologist deals with disorders involving the uterus, the ovaries, the fallopian tubes, and other organs of the female reproductive system. Such disorders may be present at birth, or they may result from infections, tumors, injuries, or improper balances of hormones (body chemicals). The gynecologist may prescribe drugs, use radiation, or perform surgery to treat the patient.

Ocarina, uhk uh REE nuh, is a small wind instrument of the whistle type. It is made of molded clay or plastic, and is shaped like an elongated egg or a sweet potato, which it is often called in the United States. It has a mouthpiece through which air is blown and 8 to 10 holes that sound a simple scale. Its tone is pleasant and soft. An Italian named Giuseppe Donati developed the standard Western ocarina in the 1860’s, but forms of the ocarina were known in ancient China. Varieties of the ocarina are often used to play folk music.

Andre P. Larson

O’Casey, Sean, shawn (1880-1964), was perhaps the greatest Irish playwright of his time. Born in the Dublin slums and largely self-educated, he gained fame when Dublin’s Abbey Theatre staged three of his plays—The Shadow of a Gunman (1923), Juno and the Paycock (1924), and The Plough and the Stars (1926). Each play deals with the violence in Ireland from 1916 to 1924, during and after its fight for independence from England. O’Casey showed egotism, slogans, and abstract ideals such as patriotism as the enemies of life and happiness. The plays are full of colorful characters and speech and are written in a vivid, realistic style.

O’Casey left Ireland for England in 1926, after The Plough and the Stars provoked rioting during its opening week. Some of the audience thought the play slandered Ireland’s patriots and womanhood. O’Casey broke with the Abbey Theatre in 1928 after it refused to stage his play The Silver Tassie. Like his earlier work, this play was antiwar in tone, and shows war as the destroyer of individuality and heroism. The play also developed expressionist tendencies found in O’Casey’s earlier work Symbolism and expressionism became more important in O’Casey’s later plays.
Most of the plays O'Casey wrote during the 1930's and early 1940's have revolutionary heroes and call for a radical transformation of society. These works include *Purple Dust* (published in 1940) and *Red Roses for Me* (published in 1942).

O'Casey returned to Irish themes late in his career. He presented an Ireland that had exchanged British domination for domination by the Roman Catholic Church of Ireland and the new commercial class. Plays of this period include *Cock-a-doodle Dandy* (1949), *The Bishop's Bonfire* (1955), and *The Drums of Father Ned* (completed in 1958). O'Casey's most important nondramatic work is an autobiography in fictional form. He died on Sept. 18, 1964.

Edward Hirsch

**Occam, William of.** See William of Ockham.

**Occultism,** uh KUHL ihz uhm, is a term that refers to a wide range of beliefs and practices involving magic or forces outside the natural world. Occultism includes astrology, fortunetelling, magic, and spiritualism—the belief that spirits of the dead communicate with the living. People who believe in occultism consider it to be based on hidden knowledge that ordinary people do not have.

Some scientists reject all occult practices. Others believe in mind reading and certain other occult powers, which they call paranormal/outside normal awareness. Opinion regarding some practices has changed through the years. Until the late 1800's, for example, most scientists considered hypnotism an occult practice. However, many scientists accept hypnotism today and use it in medicine and psychology.

Belief in occultism is most common in isolated, nonindustrial societies. But since the mid-1900's, there has been a widespread revival of occultism in the Western world.

**Occupancy, AKH yuh puhn see,** is a legal method by which a person or nation acquires title to something that no one owns. Occupancy was first recognized by the civil law of ancient Rome. It later became part of English common law.

To gain title to a thing by occupancy, a person or nation must take possession of the thing with the intention of keeping it. In some places, a person who captures a wild animal and keeps it may become the animal's owner. A person who finds lost property can gain title to it if the person who lost the property fails to reclaim it before a certain time has passed. English settlers claimed Bermuda for England by occupancy in 1609, when the islands had no other inhabitants.

Linda Henry Elrod

**Occupation.** See Careers.

**Occupational disease.** See Disease (Environmental and occupational diseases).

**Occupational medicine** is the branch of medicine that deals with diseases caused by hazards that people encounter on the job or at their workplace. Doctors in this specialty may work independently, or for a hospital or clinic. Others may have jobs with a large company, providing care for its employees. Although some specialists in occupational medicine treat workplace-related injuries and illnesses, most focus on preventing these problems by modifying the work environment.

Two important tools of occupational medicine are **epidemiology** and **toxicology.** Epidemiology is the science of investigating the causes, distribution, and control of disease by studying groups of affected people. Toxicology is the study of poisonous materials and their effects on living things.

Doctors who practice occupational medicine are always on the alert to identify diseases caused by chemicals or industrial processes. For example, one doctor noticed that several workers with a rare type of liver cancer worked with vinyl chloride, a gas used to make plastic. Using epidemiologic techniques, he showed that the workers' exposure to vinyl chloride caused this cancer. Companies worldwide took steps to prevent the disease by reducing workers' exposure to the gas.

By using knowledge of toxicology, occupational medicine specialists try to predict the diseases that chemicals could cause. Then they tell companies that use the chemicals how to protect their employees. These employees undergo periodic testing to ensure that they are not getting sick from their exposure at work. Because the doctors identify the hazards early, companies can take steps to prevent disease by reducing exposure and monitoring workers' health.

This focus on the health of both the individual and the group is a special feature of preventive medicine, the branch of medicine concerned with prevention of disease. This combined approach distinguishes an occupational medicine specialist from the other medical specialists who may treat workplace-related illnesses and injuries. Specialists in occupational medicine can save lives by identifying the cause of a disease and then sharing their discovery.

Occupational medicine is a recognized specialty in many developed countries, and the demand for specialists is great. A doctor who decides to specialize in occupational medicine receives advanced training in toxicology, epidemiology, statistical methods, and public health. The doctor can then become certified by demonstrating the level of professional competence required by national authorities.

**Occupational Safety and Health Administration (OSHA)** is an agency of the United States Department of Labor that promotes safe and healthful working conditions. OSHA's chief responsibility is the development and enforcement of job safety and health regulations. The agency also works to educate employers and employees about industrial hazards.

OSHA regulations deal with fire prevention, protective garments and railings, and many other safety matters. The rules also establish maximum levels of exposure to asbestos, lead, and other substances that could endanger the health of workers. OSHA inspectors check factories and other sites for violations, and employers who fail to make required changes are fined.

The agency encourages the states to develop their
own health and safety programs to replace OSHA itself. Many states have programs approved by the agency. The federal government pays half the cost of such programs.

OSHA was established by the Williams-Steiger Occupational Safety and Health Act of 1970 and began operating in 1971. Many leaders of both business and labor have criticized the agency's performance. Executives complain that OSHA demands too much paperwork and too many costly changes that do not increase safety. Labor leaders charge that the agency lags in developing new regulations and fails to enforce existing ones. To improve the agency's performance, OSHA began additional training programs for inspectors and planned more efficient procedures.

Occupational therapy is a form of treatment that uses everyday activities to help people with illnesses or disabilities recover, develop, or maintain practical skills. Doctors often recommend occupational therapy for patients with health problems that interfere with their ability to perform daily tasks at home, school, or work. For example, a person who uses a wheelchair may need to learn how to get around in the kitchen and prepare a meal from a sitting position. A person who has lost sight or the use of an arm or leg may need to learn new ways to bathe or dress. Occupational therapy is often called curing by doing because patients improve their own physical and mental well being by carrying out activities themselves.

Professionals called occupational therapists plan and supervise treatment activities for their patients. Occupational therapy assistants work under the supervision of an occupational therapist and do much of the hands-on work with patients, helping them learn and practice skills. Occupational therapists and assistants work in such settings as hospitals, rehabilitation centers, mental health centers, schools, facilities for older adults, and day care centers. Many occupational therapists also provide treatment in people's homes.

How occupational therapy helps patients

An occupational therapist first needs to evaluate a patient's health problems, background, and interests. The therapist uses this information to plan an individual program that will meet each patient's needs and make the most of each patient's abilities.

Helping people with physical disabilities. People who have a serious illness or injury may lose strength and coordination. For example, a person with multiple sclerosis (MS) may become weak and have difficulty balancing because the disease damages the nerves that control muscles. An occupational therapist will help an MS patient learn activities that preserve strength and maintain the greatest possible range of useful activities. In addition to teaching activities, the therapist may make a splint for the person's hand, arm, or leg to prevent weakened muscles from stretching or shrinking.

Occupational therapy plays a vital part in helping people with permanent disabilities, such as blindness or the loss of a limb. A blind person might learn to travel to a commercial district and shop alone. The therapist may help a patient find resources, such as special tools or equipment, to replace lost skills or functions. For example, someone whose arm or leg was amputated might learn to drive a specially equipped car.

Specially designed computers enable people with spinal cord injuries, blindness, hearing impairment, or cerebral palsy to communicate, operate household equipment, and find and hold a job. An occupational therapist may suggest rearranging furniture or equipment in a patient's home to make him or her more independent. The therapist may also recommend structural changes, such as widening doorways, lowering sinks and counters, and installing automatic door openers for people who use wheelchairs.

Occupational therapy helps people with chronic illnesses, such as emphysema or heart disease, redirect their interests into activities within their physical limits. For example, someone recovering from a heart attack might substitute walking for tennis.

Occupational therapy also aids people who become injured at work or develop health problems that affect their ability to do their jobs. Modifications to an employee's work environment or job responsibilities may enable the person to return to work and avoid reinjury.

Occupational therapy can also aid the growth and development of children. Many children receive treatment at school. Occupational therapists help these children interact with others, develop self-confidence, and take full advantage of opportunities in the classroom and playground. Therapists also work closely with the children's family members and teachers.

Occupational therapy for children often includes playing with toys or participating in games. A child with learning disabilities may have difficulty recognizing colors and shapes. He or she may play games that involve matching objects of different size, shape, texture, and color. A child with cerebral palsy may have difficulty
dressing. An occupational therapist might provide the child with a toy that features zippers and buttons. Playing with the toy helps the child develop the skills needed to get dressed.

Helping people with mental illness. Occupational therapists also help people who have mental and emotional illnesses, such as anxiety, depression, and schizophrenia. These illnesses may interfere with a person's ability to cope with daily life. People with mental illness may need to learn how to plan their day, how to manage stress, or how to communicate effectively with family and co-workers. A therapist can help a patient identify the most significant problem areas in his or her life. Together, the therapist and patient can plan a program of strategies to help the patient gain a sense of accomplishment and satisfaction. For example, a person who is depressed might create a daily schedule of goals and activities and check off those that have been completed.

History

Occupational therapy as a profession dates back only to the early 1900's, but people have long known that work and other activities speed recovery from illness or injury. In A.D. 172, the Greek physician Galen said, "Employment is nature's best medicine and essential to human happiness."

During the late 1700's, physicians in several countries began to prescribe useful activities as treatment for patients with mental illnesses. These doctors included Philippe Pinel in France, Johann Christian Reil in Germany, and Benjamin Rush in the United States. As early as 1798, medical professionals at the Pennsylvania Hospital for the Insane in Philadelphia taught patients such skills as carpentry, needlework, and shoe repair.

Modern occupational therapy developed from a nursing course called Invalid Occupations. This course was first offered to student nurses in 1906 by Susan E. Tracy, a Boston nurse. American architect George E. Barton originated the term occupational therapy. He himself received this form of treatment after one of his feet was amputated. The need to help disabled veterans of World Wars I (1914-1918) and II (1939-1945) stimulated the growth of occupational therapy. The World Federation of Occupational Therapists was established in Liverpool, England, in 1952.

Careers

Anyone who is interested in a career as a professional occupational therapist must first earn a bachelor's or master's degree in occupational therapy from an accredited college or university. Accredited programs include courses in biology, psychology, sociology, and occupational therapy theory and practice. All programs require students to complete a period of supervised clinical training. Most teaching, research, and administrative positions in occupational therapy require a master's or doctor's degree.

A person who wants to become an occupational therapy assistant must complete an associate degree program. Associate's programs also include academic coursework and supervised clinical training.

Upon completion of the program, graduates must pass a certification examination. Assistants must also take an exam. The American Occupational Therapy Association, Association of Occupational Therapists in Ireland, British Association of Occupational Therapists, Canadian Association of Occupational Therapists, Singapore Association of Occupational Therapists, and similar professional groups in other countries can provide information on training programs and careers.

Ocean waters cover most of Earth’s surface. This satellite view shows the Indian Ocean, partly bordered by Africa, Asia, and Australia, and below it the Southern Ocean surrounding Antarctica.

Ocean

Ocean is the great body of water that covers nearly 71 percent of Earth’s surface. People also call it the sea. The ocean serves as a source of food, energy, minerals, and recreation. Ships sail the ocean to carry cargo between continents. The sea also plays a major role in Earth’s climate system by regulating the air temperature and by supplying the moisture for rainfall. If there were no ocean, life could not exist on our planet.

The ocean contains about 97 percent of all the water on Earth. Most of the remaining water occurs frozen in ice sheets and other ice formations. The rest is underground, in the air, or in such bodies of water as lakes and rivers.

The bottom of the ocean has features as varied as those on land. Huge plains spread across the ocean floor, and long mountain chains rise toward the surface. Volcanoes erupt from the ocean bottom, and trenches and valleys plunge to great depths.

Scientists called oceanographers work to discover the

Dana R. Kester, the contributor of this article, is Professor of Oceanography at the University of Rhode Island.
ocean's secrets. They study how the ocean moves and how it affects the atmosphere. They investigate the chemical composition of seawater and monitor the forces that shape the sea floor. They also study how organisms live in the sea and how people affect the ocean.

The world ocean

The ocean forms one great connected body of water often called the world ocean or the global ocean. Geographers and oceanographers divide the world ocean into five major parts. They are the Pacific Ocean, the Atlantic Ocean, the Indian Ocean, the Southern Ocean, and the Arctic Ocean. Each ocean includes smaller bodies of water called seas, gulfs, or bays, which lie along the ocean margins. For example, the Caribbean Sea and the Mediterranean Sea are part of the Atlantic, and the Bering Sea and the South China Sea are part of the Pacific. The word sea also refers to the ocean in general.

Area. The world ocean covers about 71 percent of Earth's surface. Most of the ocean lies in the Southern Hemisphere—that is, south of the equator. The Southern Hemisphere consists of about 80 percent ocean, and the Northern Hemisphere about 60 percent.

The Pacific Ocean ranks as the largest ocean by far. It covers about 66 million square miles (171 million square kilometers)—about one-third of Earth's surface. Near the equator, the Pacific stretches about 11,000 miles (17,700 kilometers) from Panama to the Malay Peninsula. North and South America border the Pacific on the east, and Asia and Australia lie to the west. To the north, the Bering Strait links the Pacific with the Arctic Ocean. See Pacific Ocean.

The Atlantic Ocean covers about 34 million square miles (88 million square kilometers). Europe and Africa lie east of the Atlantic, and North and South America lie west. See Atlantic Ocean.

The Indian Ocean has an area of about 26.6 million square miles (69 million square kilometers). Africa lies to the west. Australia and Indonesia lie to the east. Asia borders this Ocean on the north. See Indian Ocean.

The Southern Ocean covers about 8.5 million square miles (22 million square kilometers). It surrounds the continent of Antarctica. See Southern Ocean.

The Arctic Ocean covers about 4.6 million square miles (12 million square kilometers). It is bounded by Asia, Europe, and North America. See Arctic Ocean.

Depth. The world ocean has an average depth of 13,000 feet (4,000 meters), but parts of the ocean plunge

---

Interesting facts about the ocean

**Life began in the ocean** according to most scientists. Fossils of one sea creature, pictured here, which belongs to a group of soft-bodied animals called mollusks, show that the organism has remained unchanged for over 500 million years.

**There is a bit of “ocean” inside us.** The body of an adult male contains about 19 quarts (18 liters) of salt water. The composition of this fluid is similar to seawater.

**The Atlantic Ocean’s floor spreads** about 0.6 inch (1.5 centimeters) yearly, widening the ocean basin. The Pacific floor spreads about 5 inches (13 centimeters) yearly. The edges of this floor sink under continents, so the basin does not widen.

**The world ocean would rise** about 200 feet (60 meters) if the Greenland and Antarctic ice sheets should suddenly melt. New York City would be submerged, with only the tops of the tallest buildings above water.

A tsunami—a powerful wave caused by an earthquake or underwater landslide—can reach a speed of 600 miles (970 kilometers) per hour and travel across an entire ocean.

**Giant kelp,** a large seaweed, may grow up to 200 feet (60 meters) long. Great underwater forests of kelp exist in many parts of the ocean. These forests provide shelter for numerous animals, including fish. Other animals, such as sea otters, roam the kelp forests in search of food.
much deeper. The deepest areas occur in trenches—long, narrow valleys on the sea floor. The deepest known spot is in the Mariana Trench in the western Pacific Ocean, near the island of Guam. It lies 35,840 feet (10,924 meters) below sea level. If the world’s highest mountain, 29,035-foot (8,850-meter) Mount Everest, were placed in that spot, more than 1.3 miles (2.1 kilometers) of water would cover the mountaintop.

The Java Trench is the lowest point in the Indian Ocean. It lies 23,812 feet (7,258 meters) deep. The deepest point of the Atlantic lies in the Puerto Rico Trench at 28,232 feet (8,605 meters) below the surface. In the Southern Ocean, the deepest point exists 23,737 feet (7,235 meters) below sea level at the southern end of the South Sandwich Trench. The Arctic’s deepest point lies in a deep plain north of the islands of Svalbard and
measures 13,305 feet (4,665 meters) below sea level.

**Temperature.** The surface temperature of the ocean varies from about 28 °F (−2 °C) near the North and South poles to about 86 °F (30 °C) near the equator. In polar regions, surface seawater freezes. The western tropical Pacific has the warmest surface water. Ocean currents affect surface temperature. Some currents carry warm tropical water toward the poles. Other currents bring cold surface waters from the poles toward the equator.

Ocean temperature also varies with depth. In general, the temperature falls as the depth increases. The warm surface waters extend to depths of about 500 to 1,000 feet (150 to 300 meters). Below the surface waters, the temperature decreases rapidly, forming a layer called the thermocline. The thermocline varies in thickness, from about 1,000 to 3,000 feet (300 to 900 meters). From
the thermocline to the sea floor, the temperature decreases more slowly. Ocean temperature ranges between 34 and 39 °F (1 and 4 °C) near the bottom. In some regions, colder and deeper water rises to the surface, lowering the surface water temperature.

**Composition.** The ocean likely contains every natural chemical element. But the sea is best known for its salts. On average, the weight of seawater contains about 3.5 percent salts. Eleven ions, or molecules with electrical charges, account for the ocean’s salinity (saltiness). They are, in order of concentration, chloride, sodium, sulfate, magnesium, calcium, potassium, bicarbonate, bromide, borate, strontium, and fluoride. The most abundant form of salt consists of the ions sodium and chloride.

Many ions in the ocean come from the dissolving of rocks on land. As rocks break down, rivers carry the resulting ions to the ocean. Volcanoes and undersea hot springs also contribute ions to the ocean. Evaporation and precipitation further affect ocean salinity. Evaporation removes fresh water from the ocean surface, leaving behind salts. Precipitation, however, returns fresh water to the ocean. Evaporation in subtropical areas is greater than precipitation, so these areas have especially salty surface waters. Closer to the equator, precipitation is greater than evaporation, making surface waters less salty there. Rivers also bring fresh water to the ocean, which lowers the salinity of seawater near river mouths.

**The importance of the ocean**

**As a wealth of resources.** The ocean provides many major resources. They include (1) food, (2) sources of energy, (3) sediments, and (4) medicines.

**Food** from the ocean consists mainly of fish and shellfish. Most of the catch comes from coastal waters. The world’s fishing fleets harvest many kinds of fish and shellfish. The chief kinds include anchovies, cod, haddock, herring, lobsters, mackerel, oysters, sardines, shrimp, and tuna. The fishing industry also is developing new products and markets to make use of less familiar types of seafood. For example, *surimi*, a fish product developed in Japan, can be made into imitation crab, lobster, scallop, and shrimp. Processors use many fish not traditionally eaten, including certain species of flounder, to make protein powders with which to enrich foods.

Seaweeds also serve as a source of food, in addition to having industrial uses. *Kelp*, a large seaweed, is one of the most important. Kelp contains such nutrients as iodine and potassium. However, its chief value is as a source of *algae*, a thickening substance used in ice cream, salad dressing, cosmetics, and other products.

People farm the ocean much as they farm the land. In a type of farming called *aquaculture* or *mariculture*, farmers raise fish, shellfish, and seaweeds near ocean shores as well as in ponds. They use special methods to make the animals and seaweeds grow faster and larger than they would in the wild. Fish hatcheries produce healthy young salmon and other young fish for release into the ocean. See **Aquaculture**.

**Sources of energy** from the ocean have several forms. Petroleum and natural gas rank as the ocean’s most valuable energy resources. Offshore wells tap deposits of oil and gas beneath the sea floor. Today, about 30 percent of worldwide oil and gas comes from offshore production. Scientists estimate that from 63 billion barrels to as much as 530 billion barrels of oil lie undiscovered beneath the ocean. One barrel equals 42 gallons (159 liters). Equally huge amounts of untapped gas accompany the oil. As gas and oil reserves on land are used up or become too difficult and expensive to obtain, undersea deposits will become increasingly important. See *Gas* (Producing gas); *Petroleum* (Offshore drilling).

The ocean tides also provide energy. Tidal power facilities use the energy in the rise and fall of the tides to produce electric power. Unlike petroleum and gas, this source of energy is renewable. The first tidal power plant opened in 1966 on the Rance River near St.-Malo, France. Ocean waves also provide potential sources of renewable energy. See **Energy supply** (Tidal energy).

**Sediments** are materials deposited at the bottom of the ocean. Ocean sediments collect as sand, mud, minerals, and other materials. Important sediments recovered from the ocean include sand and gravel mined from the sea floor and used to make construction materials. People also use some sand to restore damaged beaches. Seawater itself contains such important minerals as bromide and magnesium. These minerals can be removed by letting seawater evaporate in large shallow basins under sunlight. The evaporation leaves the mineral deposits behind in the form of salts. The salts themselves and such elements as magnesium and bromide can be extracted from the deposits. Other methods to remove minerals from seawater include chemical and electrochemical processes.

The mineral wealth of the ocean extends to the deep sea floor. The deep-sea floor contains vents from which hot water flows. Deposits at these **hot vents**, also called *hydrothermal vents*, contain copper, iron, and zinc. But mining the oves would prove expensive and difficult, and the techniques must still be developed. Manganese deposits lie on the ocean bottom in lumps called *nodules*. The nodules also contain valuable amounts of cobalt, copper, and nickel. Possible techniques to mine these nodules include using buckets that run on conveyors or belts between a ship and the sea floor, or operating devices that work like a giant vacuum cleaner.

**Medicines** may be produced from many forms of marine life. For example, plantlike organisms called *red algae* could provide antibioagulant drugs that keep blood from clotting. A family of marine snales produces substances that may treat pain. Sea life has also aided medical research. The blood of horseshoe crabs contains a substance used to test for infections and bacteria contamination. Researchers study nerve cells from lobsters, squids, and marine worms to learn more about how the human nervous system functions.

**Other products** from the ocean include coral, pearls, and shells used in jewelry. Many people believe that natural sponges from the ocean bottom are of higher quality than synthetic sponges. In many dry areas near seacoasts, people *desalinate* (remove the salt from) seawater to produce fresh water for drinking and industrial uses (see **Water** [Fresh water from the seal]).

**As an influence on climate.** The ocean helps stabilize Earth’s climate. The ocean’s great size and the slowness of water to change temperature have a steadying influence on the temperature of the atmosphere. In summer, the ocean stores heat from the sun. In winter, when the sunlight is weaker, the ocean releases the
stored heat into the air. Currents carry the heat of tropical waters toward the poles, thereby cooling the tropics and warming the polar regions.

The ocean is the source of most precipitation that falls to the earth. The sun's heat evaporates water from the ocean surface. The water rises as invisible vapor and forms clouds as it cools. It then falls back to the earth as rain, sleet, hail, or snow.

As a vast highway. The ocean has been a highway for trade since people built the first ships thousands of years ago. Shipping ranks as an important use of the ocean in international trade. See Ship; Transportation.

Life in the ocean

An incredible variety of living things resides in the ocean. Marine life ranges in size from microscopic one-celled organisms to the blue whale, which may measure up to 100 feet (30 meters) long. In a process called photosynthesis, ocean plants and plantlike animals use sunlight, carbon dioxide, water, and nutrients to produce their own food and materials for growth. Sea animals eat these organisms and one another. Marine plants and plantlike organisms can live only in the sunlit surface waters of the ocean, which is called the photic zone. The photic zone extends only about 330 feet (100 meters) below the surface. Beyond that point, the light is insufficient to support organisms that rely on photosynthesis. Animals, however, live throughout the ocean, from the surface waters to the greatest depths.

Three basic categories of marine organisms inhabit the oceans. They are (1) the plankton, (2) the nekton, and (3) the benthos.

The plankton includes plantlike organisms and animals that drift with ocean currents. They have little ability to move through water on their own. Most of them are so small that they cannot be seen without a microscope. Plantlike organisms of the plankton are called phytoplankton, and they include such simple creatures as diatoms and other algae. Animals of the plankton are among the organisms known as zooplankton.

Phytoplankton consist of several kinds of plantlike organisms. Most have only one cell and float in the photic zone, where they obtain sunlight and nutrients for photosynthesis. Although the organisms generally drift about, some kinds have long, whiplike parts called flagella that enable them to swim. Phytoplankton serve as food for zooplankton and some larger marine animals.

The most numerous phytoplankton are diatoms and dinoflagellates. A diatom consists of one cell enclosed in a hard, glasslike shell made of silica. Diatoms live mainly in colder regions of the ocean. Some even live within sea ice. Most dinoflagellates also are one-celled organisms. They generally live in more tropical regions. A dinoflagellate has two flagella it can use to move in a swirling motion. Sudden increases in certain dinoflagellate populations are called red tides, from the reddish discoloration that millions of these cells create in the water. Some dinoflagellates produce powerful poisons. When such species become plentiful, they may create a red tide that kills many sea animals (see Red tide). Other kinds of phytoplankton include coccolithophores, one-celled organisms with a hard shell made of calcite; and silicoflagellates, which have a skeleton of hollow silica ods.

Zooplankton consist of many kinds of creatures, such as single-celled organisms and small animals that are unable to swim. They live at all depths in the ocean. Some planktonic animals float about freely throughout their lives. The rest spend only the early part of their lives as plankton. As adults, some become strong swimmers and join the nekton. Others settle to the sea floor or attach themselves to it and become part of the benthos. Crustaceans, a large group of invertebrates (animals without backbones), make up about 70 percent of all zooplankton. Tiny swimmers called copepods are the most numerous crustaceans. Shrimplike krill, another group of crustaceans, provide food for fish, sea birds, seals, squids, and whales.

The nekton consists of animals that can swim freely in the sea. They are strong swimmers and include fish, squids, and marine mammals. Most nektonic species live near the sea surface, where food is plentiful. But many other animals of the nekton live in the deep ocean.

Fish rank among the most important animals of the nekton. About 14,500 kinds of fish live in the ocean. The smallest fish, a goby with the scientific name Trimmatom nanus, lives in the Indian Ocean. It grows to about 0.4 inch (1 centimeter) long. The largest fish, the whale shark, measures as much as 40 feet (12 meters) long. Such fish as tuna and mackerel have streamlined bodies that enable them to swim rapidly through the water. Many fish of the deeper parts of the ocean have light-producing organs that may help attract prey. Such fish include deep-sea anglerfish and lanternfish.

Squids are free-swimming mollusks, a group of soft-bodied invertebrates, and have eight arms and two tentacles. Related animals include octopuses and cuttlefish. Squids live in surface and deep waters. They measure from less than 1 foot (0.3 meter) to as much as 60 feet (18 meters) long, including the tentacles. A squid moves backward through the water in a jetlike action by forcing water through a tube beneath its head.

Nektonic mammals include dugongs, manatees, porpoises, and whales, all of which remain in the ocean for their entire lives. Other marine mammals, such as sea otters, seals, and walruses, also spend time on land.

The benthos is made up of marine organisms that live on or near the sea floor. Animals of the benthos may burrow in the ocean floor, attach themselves to the bottom, or crawl or swim about within the bottom waters. Where sunlight can reach the sea floor, the benthos supports plants and plantlike organisms, such as kelp and sea grass, which become anchored to the bottom. Common benthos animals include clams, crabs, lobsters, starfish, and various worms. Some fish have features specially suited for life on the sea floor. For example, halibut and sole, which lie sideways on the bottom, have both eyes on the side of the head facing up.

Most bottom-dwelling creatures are part of the plankton and drift with the currents during the early stages of their development. They then sink to the sea floor where, as adults, they become part of the benthos. Such animals include barnacles, clams, corals, oysters, and a variety of snails and worms.

The food cycle in many parts of the sea begins with the phytoplankton that produce food by photosynthesis. Certain zooplankton eat the phytoplankton. Those animals, in turn, become food for other zooplankton or for
Life in the ocean

The ocean contains a remarkable variety of life, from tiny microorganisms to gigantic whales. Different kinds of organisms inhabit different levels of depth in the ocean waters.

**Plankton**

Plankton consists mostly of small marine organisms that drift with ocean currents. The plantlike organisms are called *phytoplankton*. Planktonic animals are among the organisms known as *zooplankton*.

**Phytoplankton**

- Hydromedusa

**Nekton**

Nekton is made up of fish and other animals that have the ability to swim freely in water without the help of currents. Most nektonic creatures live in the upper layer of the ocean.

**Benthos**

Benthos consists of marine organisms that live on the ocean bottom. Some members of the benthos are attached to the bottom in one position throughout their lives.

- Anchovies
- Loggerhead turtle
- Common squid
- Butterflyfish
- Angelfish
- Sea lion
- Red sea anemone
- Sculpture coral
- Vase sponge
- Crinoid
- Kelp
- Starfish
The ocean’s cycle of life

The creatures of the ocean make up a complex web of life. For most marine life, the food cycle begins with tiny organisms called plankton. Plantlike phytoplankton use sunlight, carbon dioxide, water, and nutrients in the water to make food. Zooplankton, which are animals, eat phytoplankton or other zooplankton. These organisms, in turn, serve as food for fish, whales, and other animals that swim, called the nekton. Many larger creatures of the nekton eat smaller nektonic animals. Animals of the benthos (sea floor), such as sponges and sea lilies, depend on organic debris falling from the upper ocean. Finally, upwellings (deep waters that rise to the surface) carry waste products and other organic debris back to the surface, where they serve as nutrients for the phytoplankton.

WORLD BOOK illustrations by George Fryer, Bernard Thornton Artists
fish and other animals of the ocean.

After ocean organisms die, they begin to sink. Before most dead organisms sink far, they are eaten by creatures dwelling at lower depths. Dead organisms that are not eaten immediately begin to decompose. Bacteria and fungi cause the organisms to decompose by breaking them down into nutrients (nourishing chemicals). In addition, bacteria and fungi break down waste products given off by marine life. Rising currents carry the nutrients to the surface, where phytoplankton use them for photosynthesis, completing the food cycle.

Hot vents support thriving communities of marine life. However, the food cycle at hot vents is not based on phytoplankton. Instead, such microscopic organisms as bacteria and archaea serve as the food base. Archaea are single-celled organisms that rank among the oldest forms of life on Earth. In a process called chemosynthesis, these microorganisms use energy from chemicals in the water instead of sunlight to produce food and grow. Other living things rely on archaea for food.

**How the ocean moves**

Ocean currents move through the sea like giant meandering rivers. Winds and earthquakes create waves across the surface of the ocean. The gravitational pull of the moon and sun causes movement, producing the daily rise and fall of the tides.

**Circulation.** Two main types of circulation exist in the ocean. They are (1) wind-driven currents and (2) thermohaline circulation.

**Wind-driven currents** result from wind blowing on the ocean surface. The wind sets surface waters into motion as currents. Currents generally flow horizontal-ly—that is, parallel to Earth's surface. The wind mainly affects only the upper 330 to 660 feet (100 to 200 meters) of water. However, the flow of wind-driven currents may extend to depths of 3,300 feet (1,000 meters) or more.

Wind-driven currents move in enormous circular patterns called gyres. Gyres flow clockwise in the subtropics of the Northern Hemisphere and counterclockwise in the subtropics of the Southern Hemisphere. Several conditions influence the direction of wind-driven currents and make them form gyres. Earth's wind systems drive the currents in an easterly or westerly direction. Continents direct the flow toward the north or south. Earth's rotation further causes the currents' circular paths. Major wind-driven currents include the North and South Equatorial currents, the California Current, the Canary Current, the Gulf Stream, the Kuroshio (Japan Current), the Labrador Current, and the Peru Current. The Antarctic Circumpolar Current is the strongest ocean current and the only one that circles Earth with- out hitting continents. See the world ocean map in this article for the location of the major currents.

In some areas, upwelling occurs when winds cause surface waters near the coast to move offshore. Colder, deeper waters, which are rich in nutrients, then rise to the surface near the coast. The upwelling of deeper waters provides nutrients for the growth of phytoplankton, which fish and other sea animals eat. Upwelling areas have great numbers of fish and, in fact, yield half of the world's fish catch. Important upwelling regions include the coasts of Peru and northwestern Africa, as well as along the equator and around Antarctica.

**Thermohaline circulation** produces great vertical movements of water that flow from the surface to the

---

*Ocean currents* result from two forces: (1) the action of the wind on surface waters, and (2) the differences in temperature and salt content of surface and deeper waters. The earth's general wind circulation produces the major currents—great streams that carry the ocean's surface waters in roughly circular patterns. Wind also causes upwelling, which occurs when coastal waters are blown offshore and replaced by colder, deeper waters. **Thermohaline circulation** takes place because colder, saltier water sinks. This action produces great vertical currents in the ocean.

---

*WORLD BOOK* illustration by Sarah Woodside
The ocean as a conveyor belt
Thermohaline circulation produces a worldwide current comparable to a conveyor belt. Cold, dense waters descend from the surface in the North Atlantic and spread first to the Southern Ocean, then around Antarctica, and then into the Indian and Pacific oceans. In the North Pacific, the waters migrate upward as they become warmer and less saline. They then travel back to the Indian Ocean and through the southern Atlantic. The waters eventually reach the North Atlantic, where the conveyor belt begins again.

Ocean depths. The circulation results from differences in water temperature and salinity. In the polar regions, surface waters are colder and saltier. Being colder and saltier makes these waters heavier, and they sink toward the ocean bottom. They then gradually flow back toward the surface and replace the surface waters that sink.

Thermohaline circulation produces a worldwide circuit comparable to a conveyor belt. Cold, dense waters descend from the surface in the North Atlantic and spread southward in deep areas of the ocean. Upon reaching the Southern Ocean, these waters sweep eastward around Antarctica and then spread northward into the Indian and Pacific oceans. In the North Pacific, the waters migrate upward as they become warmer and less saline. They then follow the surface circulation, returning southward into the Indian Ocean and through the southern Atlantic around the Cape of Good Hope. They eventually reach the North Atlantic, where the conveyor belt begins another global circuit. Such waters take about 1,000 years to make one complete circuit.

Waves. In addition to creating currents, wind produces the up and down movements of an ocean wave. As forward motion of water occurs as a wave goes through the water. The action of an ocean wave resembles waves you can make in a rope that is tied to a tree. You shake the rope's free end, waves run along it. But the rope itself does not move forward. When an ocean wave reaches land, however, it starts to drag on the bottom. The wave becomes steeper and breaks, producing a rush of water against the shore called surf. See Waves. Ocean waves vary in size from small ripples to giant hurricane waves more than 100 feet (30 meters) high. Wave size depends on wind speed, on how long the wind blows, and on how far it blows over the ocean. Heavier storms cause longer waves.

Waves created by strong winds in the open ocean may become so steep that they break in a manner similar to surf. These breaking waves are called whitecaps.

The action of ocean waves changes the shoreline. Waves cut away sloping land and leave steep cliffs. They erode exposed rocks and form beaches. The movement of the waves and currents shapes beaches and builds up sand bars along the shore. Waves also carry beach sand away, particularly during storms.

Another type of wave results from sudden movements of the sea floor that are usually caused by earthquakes or underwater landslides. Scientists call such waves tsunamis. Some people call these waves tidal waves, though the tide does not cause them. On the surface of the open ocean, tsunamis can barely be seen. The waves typically measure about 3 feet (1 meter) high or less. But they can travel as fast as 600 miles (970 kilometers) per hour. As they approach a coast, they slow down and may pile up to a tremendous height, causing great damage along the coast. Most tsunamis strike land areas in or bordering the Pacific Ocean. Sometimes, scientists can predict when a tsunami may form and warn people in its path. See Tsunami.

Tides are the rhythmic rise and fall of ocean waters. In many coastal areas, water slowly rises along the shoreline for about six hours every day. Then it slowly falls back for about six hours. Tides are caused chiefly by the gravitational pull of the moon on Earth. The moon's gravity is strongest on the surface of Earth directly facing the moon. When ocean waters face the moon, the moon's gravity pulls the water up and forms a high tide in that area. The moon's gravity is weakest on the side of Earth opposite from the moon, enabling water there to move away from Earth as it rotates. This action produces another high tide bulge. As Earth rotates each day, high tide bulges move around the planet.

The sun's gravitational pull also affects the ocean. But the sun causes tides only about half as high as those caused by the moon. The gravitational pull of the moon and sun combine during the full moon and new moon. At such times, the sun, moon, and Earth are in a straight line. The tides then rise higher and fall lower than usual. They are called spring tides. When the moon is in its first and third quarters, the sun and moon are at right angles to each other with respect to Earth. The resulting tides do not rise or fall as much as usual. They are called neap tides. See Tide.

The land at the bottom of the sea
The ocean floor is a region of spectacular contrasts. Broad plains cover huge distances, towering mountain
The land beneath the oceans

The geography of the land beneath the oceans features long mountain ridges, broad basins, and deep trenches. This computer-generated map shows many of the major landforms of the ocean floor. Oceanographers created the map using information gathered from a variety of sources, including radar equipment from satellites and sonar devices on ships and in the sea. Deeper elevations on the map appear in darker colors, while shallower elevations appear in lighter colors. The map index below indicates the locations of individual sea floor features.

chains circle the planet, undersea volcanoes rise toward the surface, and trenches and valleys reach great depths. The continental margin forms the part of the seabed that borders the continents. It consists of (1) the continental shelf, (2) the continental slope, and (3) the continental rise. The continental shelf is the submerged land at the edge of the continents. It begins at the shoreline and...
gently slopes underwater to a depth less than 660 feet (200 meters). The width of the continental shelf usually ranges between 19 and 190 miles (30 and 300 kilometers). In certain areas, such as parts of the Arctic Ocean, the shelf extends over 620 miles (1,000 kilometers). In other areas, particularly those bordering much of the Pacific, it measures only 1 mile (1.6 kilometers) or less. Valleys of varying depths cut through the shelf. Sediment carried into the ocean by rivers collects on the shelf.

The continental slope begins at the outer edge of the shelf. The slope is much steeper than the shelf and plunges to depths of 2.2 miles (3.6 kilometers). The slope forms the sides of continents. Its width ranges from 12 to 60 miles (20 to 100 kilometers). In many places, deep underwater canyons gash the slope. Some canyons rival the gigantic Grand Canyon of North America in size. Many underwater canyons lie offshore from large rivers, and sediment-laden waters may have carved them.

The continental rise consists of sediment from the continental shelf and slope that accumulates at the bottom of the slope. The thick sediment deposits of the continental rise extend up to about 600 miles (1,000 kilometers) from the slope.

Deep-sea peaks, valleys, and plains lie beyond the continental margin in the ocean basin. Mid-ocean ridges form a chief feature of the basin. The ridges consist of a chain of mountains that runs about 37,000 miles (60,000 kilometers) through the world ocean. Scientists discovered the mountain chain independently in each ocean basin and gave it different names, including Mid-Atlantic Ridge, East Pacific Rise, and Mid-Indian Ridge. Most mountains of the mid-ocean ridges stand about 5,000 feet (1,500 meters) above the sea floor. Some peaks rise above the surface and form islands, such as the Azores and Iceland in the Atlantic Ocean. Deep valleys often cut across the ridges, producing a rugged, fractured surface. Some mid-ocean ridges have valleys down through the center of them. Frequent volcanic eruptions and earthquakes occur along such valleys.

The sides of the mid-ocean ridges slope down to the abyssal plains. Accumulation of sediment buries most features of the ocean floor on the abyssal plains, which are flat as a result. The chief sources of deep-sea sediment are the land itself and marine life. The breaking down and wearing away of rock produces land sediment, which rivers carry to the ocean. Wind also carries dust from deserts and other regions to the ocean. In addition, volcanic eruptions spread large amounts of ash over the ocean. Marine life sediment consists mainly of tiny shells and the remains of dead planktonic organisms. When such biological matter makes up a major part of a sediment, scientists call it ooze (see Ooze).

Other features of the deep-sea basin include the long, narrow trenches and underwater mountains called seamounts. Trenches form the deepest parts of the ocean. Volcanic eruptions produce seamounts. These mountains have steep sides and may rise thousands of feet or meters above the sea floor.

How the sea floor was formed. Since the late 1800's, scientists have developed several theories to explain how the sea floor was formed. The theory of continental drift first received wide attention during the early 1900's. According to this theory, the continents originally consisted of a single great land mass surrounded by one ocean. The land mass broke up into continents, which slowly drifted apart. New oceans, including the Atlantic and the Indian oceans, resulted from the drift of the continents.

At first, many scientists rejected the continental drift theory because no one could explain what forces might move continents. Then in the 1960's, a theory called seafloor spreading provided some explanation. According to the theory, the sea floor itself moves, carrying the continents along. Circulating movements deep within Earth's mantle—that is, the partly molten layer of hot rock beneath the earth's crust—make the sea floor move. The circulating movements carry melted rock up to the mid-ocean ridges and force it into the central valleys of the ridges. As the melted rock cools and hardens, it forms new sea floor and pushes the old floor and the continents away from the ridges.

A theory called plate tectonics combines and expands on the ideas of seafloor spreading and continental drift. According to plate tectonics, Earth's outer shell consists of huge rigid plates that move continuously. As the plates move, they carry the ocean floor and the continents with them. The relative movement of two neighboring plates is generally about 0.5 to 4 inches (1 to 10 centimeters) a year. Sea-floor spreading—and the formation of new sea floor—occurs where plates move apart. The mid-ocean ridges mark such areas.

As plates move away from one another in one place, they must move toward one another elsewhere. When two plates collide, one may pile up against the other, forming mountains. Or one plate may be drawn down into the mantle under the other plate. Such action produces trenches and volcanoes. Earthquakes occur at or near plate boundaries, where plates spread apart, collide, or slide past each other. The Atlantic Ocean is slowly growing wider, and the Pacific smaller, because of plate tectonics. See Earth (Earth's plates); Plate tectonics.

The oceanic crust forms the ocean floor. It consists of hard rock called basalt. The continents lie on the continental crust, which consists mainly of granite. Granite is lighter than basalt, and so the continental crust basically "floats" on the mantle, above the oceanic crust. Ocean basins, as sunken areas, thus collect water. Most scientists believe that the water now filling the oceans came from a number of asteroids and comets that struck Earth as it formed nearly 4.6 billion years ago. Much of it was released from rocks within Earth by volcanic activity.

Exploring the ocean

By exploring and understanding the ocean, we can learn to manage its resources wisely.

Tools of exploration. The tools that oceanographers use in their efforts to explore the sea include (1) research ships, (2) research submarines called submersibles, (3) satellites, and (4) computers.

Research ships typically measure about 100 to 300 feet (30 to 90 meters) long and include laboratory space where scientists can work while at sea. Oceanographers use research vessels to make measurements, perform experiments, and study marine processes. They may sail at sea for weeks or months at a time. They often work in rough seas and in distant locations around the world.

Oceanographers use several types of instruments on research ships. They operate underwater cameras to
photograph the sea floor. Electronic devices measure the depth of the sea by sending out sound waves and recording their echoes from the ocean floor. The most powerful of such instruments detect echoes from deep within Earth’s crust. Scientists analyze the records to learn about the structure of the crust. Oceanographers also measure temperature, salinity, and a wide array of chemicals in the ocean. Nets towed behind research ships gather samples of marine life for study.

Oceanographers also use a number of floating devices. For example, a mooring consists of an anchor and a float connected by a cable. The float may be placed at the sea surface or at a specific depth. Scientists attach various instruments to the cable of a mooring. Some instruments measure the speed and direction of ocean currents at different depths. Other devices record the temperature and salinity of the water. A mooring may remain at sea several years before the research ship picks up the device and the data it has collected.

Other floating devices include buoys, which drift with the ocean’s surface currents. Buoys chiefly provide information about ocean circulation. But they may also record air pressure or surface water temperature. Buoys relay data to scientists through orbiting satellites. Some buoys can drift with currents below the ocean surface.

Oceanographers use specialized equipment to collect samples from the ocean bottom. Scientists can gather rock samples from the mid-ocean ridge by towing a dredge along the sea floor. Other ships can drop long, heavy pipes into the sea floor to collect vertical samples of sediments called cores. Because sediments are deposited in layers over time, studies of cores can determine how old the sediments are. The age and composition of the sediments can reveal how oceans have changed over time. See Ocean Drilling Program.

Submersibles can descend to the depths of the ocean. They enable scientists to observe features on the sea floor that may be missed by instruments lowered from research ships on the surface.

Piloted submersibles, such as the U.S. Alvin, carry a human crew. The crew members take photographs and use a mechanical arm outside the vessel to gather samples and set out instruments.

Other submersibles, called remotely operated vehicles (ROVs) or autonomous underwater vehicles (AUV’s), carry no crew. ROV’s usually are controlled from a ship by a cable. They have television cameras and sensors that can return information about the sea floor environment. In 1985, two remotely operated submersibles—the U.S. Argo and the French Sar—found and explored the wreckage of the Titanic, a British passenger ship that sank in the Atlantic in 1912. AUV’s are self-contained vehicles controlled by an onboard computer programmed with instructions. They can explore specific areas of the ocean, take measurements, and collect samples. AUV’s return to the control ship or station to recharge batteries, return data and samples, and receive new instructions in their computers. See Diving, Underwater.

Satellites transmit data from buoys and other instruments at sea to oceanographers on shore. They also provide views of vast expanses of the sea from their position high above Earth. In general, satellites supply information more quickly over a larger area than do research ships.

Satellite images can show the distribution of sea ice, the extent of surface oil slicks, and the cloud formations over the ocean. Satellites can help map the temperature and color of the ocean surface. Some satellites can even detect the small differences in the elevation of the sea surface caused by ocean currents. Such data help oceanographers in many ways. For example, scientists can study variations in the routes and patterns of ocean currents and their effects on climate and weather. Researchers can also determine biological activity in the ocean’s surface waters, as well as understand how the

The submersible Alvin can carry a crew of scientists to the ocean floor, where they take photographs and gather samples.
ocean affects weather and climate.

Computers enable oceanographers to collect and analyze the enormous amounts of data obtained every day from satellites, from instruments on research ships, and from buoys. Scientists also use computers to create models (mathematical representations) of the ocean's movement and structure. The models enable them to understand and predict the ocean's behavior and its effect on the environment.

Discoveries. Oceanographers constantly make new and interesting discoveries about the sea. One of the exciting discoveries occurred in 1977, when scientists first detected a hot vent on the sea floor near the Galapagos Islands in the eastern Pacific Ocean. Similar vents have been found elsewhere in the eastern Pacific and along portions of the Mid-Atlantic Ridge. Hot vents occur at depths of about 8,200 to 10,000 feet (2,500 to 3,000 meters) on the mid-ocean ridges, where new sea floor forms as the tectonic plates move apart.

Hot seawater containing such chemicals as copper, iron, manganese, zinc, and sulfate flows from the vents. As the hot water mixes with colder seawater containing oxygen, chemical reactions form dark-colored mineral particles. These particles produce deposits around the vents. The deposits take the shape of "chimneys" through which the water shoots out. The dark-colored minerals make the water look like black smoke, and so these hot vents are called black smokers.

Communities of strange marine life live at hot vents. Scientists discovered that some kinds of bacteria and archaea that live there use chemosynthesis to produce food. Such organisms serve as the base of the food chain for the vent communities. Scientists previously thought that all food chains throughout the ocean began with the energy from sunlight and the photosynthesis that takes place in shallow waters. Other forms of life found near hot vents include clams up to 1 foot (30 centimeters) long and giant tubeworms measuring up to 10 feet (3 meters) long. Scientists have also discovered various species of crabs, fish, shrimp, and other animals in the vent communities. Most of the animals were previously unknown species of marine life.

Oceanographers often make discoveries as they apply new instruments and techniques to study the ocean. The use of specialized research ships, satellites, and computers has increased their knowledge of oceanic processes. For example, such technology has enabled us to better understand the effects of El Niño in Earth's weather and climate systems. El Niño is an interaction between the atmosphere and the waters of the Pacific Ocean that occurs about every two to seven years. During an El Niño, a warm current flows southward along the west coast of South America, warming the normally cold coastal waters of Ecuador and Peru. The warming of the ocean waters kills many fish and the sea birds that rely on fish for food. A typical El Niño lasts about 18 months.

For years, El Niño was considered only a local phenomenon. In the 1960s, however, scientists observed a connection between El Niño and a change in the normal trade winds over the tropical Pacific Ocean. In the 1990s, oceanographers used a variety of ships, satellites, and electronic instruments to study the ways in which the tropical ocean and atmosphere interact to produce El Niño events. They discovered that El Niño and an oppo-

site pattern called La Niña that often follows are part of a larger atmospheric pattern known as the Southern Oscillation. El Niño studies have also enabled scientists to predict El Niño events—and their effects—from 6 to 18 months in advance. These effects include rainfall and drought conditions, as well as severe forest fires and floods. See El Niño.

International cooperation. Increasingly, many countries now cooperate with one another in conducting scientific studies of the ocean. Major international investigations have studied such issues as the circulation of ocean waters, the changes in the sea's chemical content, and the structure of marine ecosystems. In addition, efforts are underway to develop a global ocean observing system to better understand natural and human-induced changes in the marine environment.

Ocean problems

For thousands of years, people used the ocean and its vast resources with little concern for their conservation. But during the last two centuries, increases in human population, industrial development, and use of coastal regions has put the health of the sea at risk, forcing people to address ocean conservation problems. Many of the major problems involve marine pollution, depletion of fisheries, habitat modification, and climate change.

Marine pollution. Pollutants (substances that cause pollution) enter oceans through accidents, carelessness, and the deliberate disposal of wastes. The ocean can absorb some types of pollutants in certain quantities because of its great size and the natural chemical processes that occur within it. But the ocean's capacity to absorb and recycle pollutants can become overwhelmed.

People pollute the oceans in several ways. Major ocean pollutants include waste products, which people often dump deliberately into the ocean, and oil, which usually enters the sea by accident.

Waste products that enter the ocean include sewage, plastic litter, and industrial wastes. Sewage, such as human waste and ground-up garbage, often fouls coastal regions. This kind of waste contains organic matter that decomposes and reduces the levels of oxygen in the water. Low oxygen levels make the water unfit for animals. Sewage also contains nitrates, phosphates, and other nutrients that stimulate the growth of phytoplankton. An overabundance of certain phytoplankton produces a condition called eutrophication, which also reduces the water's oxygen levels. Rapid growth of some phytoplankton can create red tides. Red tide phytoplankton produce toxins that poison marine life.

Plastic litter can severely damage the ocean because it does not break down easily. Sea birds, turtles, seals, whales, and other marine animals can get tangled in plastic nets, bags, and packing material. These animals may also mistake plastic items for food and die of starvation if the plastic blocks their digestive system. In addition, plastics and other litter make the marine environment less attractive. Many countries ban the disposal of plastics into the ocean, but such litter remains a common problem on shorelines.

The deliberate dumping of industrial waste into the sea from ships and barges has also polluted oceans. Such wastes have included ash from power plants, contaminated sediments dredged from harbors, and even
radioactive wastes. Since the 1970s, many countries have begun banning ocean dumping of most wastes. But the disposal of some types of wastes, such as dredged sediments, may likely continue.

Oil pollution enters the ocean from oil spills on land or in rivers. Oil also seeps into the ocean naturally from cracks in the sea floor. Oil tanker and oil well accidents at sea account for only a small portion of ocean oil pollution, but their effects may be disastrous. The world's largest accidental oil spill occurred in June 1979, when an oil well blew out off the east coast of Mexico and spilled about 140 million gallons (530 million liters) of oil. The world's largest oil spill occurred when Iraq deliberately released between 240 million and 465 million gallons (910 million and 1,760 million liters) of oil into the Persian Gulf during the Persian Gulf War (1991). In water, much of the oil forms tarlike lumps, which foul beaches and other coastal areas. Oil also coats fish, birds, and mammals and kills many of them.

Fisheries. Since the latter part of the 1900s, the world's fishing industry has harvested fish from many ocean fisheries faster than the fish stocks can renew themselves. Some fishing techniques have proved especially destructive. These techniques include the use of dynamite and cyanide to stun or kill fish on coral reefs. They also include the use of nets that capture, injure, or kill species other than the ones being sought. In some cases, the depletion of commercially valuable fish species can alter marine ecosystems by making less valuable species more abundant. Such problems have led many countries to enforce limits on catch and even temporarily close a number of valuable fisheries.

Habitat modification. People have harmed marine ecosystems in many coastal regions by destroying such vital habitats as marshes; mangrove swamps, where the spreading roots of mangrove trees catch and hold silt from the water; and tidal flats, which are covered and uncovered twice daily by the tides. These environments often play an essential role in maintaining a healthy marine ecosystem. As a result, conservationists are attempting to stop further damage to such habitats and, in some cases, to restore the habitats to their natural state.

Climate change. Natural processes cause most kinds of climate change. But increasing evidence indicates that human activities can also produce changes in climate. Over the past 150 years, the combustion of such fossil fuels as petroleum, coal, and natural gas has increased the amount of carbon dioxide gas in the atmosphere by about 30 percent. Carbon dioxide traps heat from the sun in a process called the greenhouse effect. Increases in atmospheric carbon dioxide may enhance the greenhouse effect and significantly raise temperatures on earth. Such changes in climate could greatly affect all marine ecosystems. See Greenhouse effect.

Scientists are working to determine the role of the ocean in climate, as well as the effects of human activities on climate change. Scientists have studied the possibility of disposing of carbon dioxide into the depths of the ocean as a way to keep Earth from overheating.

Who owns the ocean? This question has become more important as countries have learned that fish and other ocean resources can be used up and that valuable minerals and sources of energy lie on and under the sea floor. The United Nations has worked to develop an agreement on ownership of the sea. Its efforts resulted in the Law of the Sea Convention, drafted in 1982. This treaty went into effect in 1994, after more than 60 nations ratified it. The treaty provides for a system to protect the economic and environmental interests of coastal nations, while allowing the free passage of other countries' ships.

Under the Law of the Sea Convention, the laws of a coastal nation apply throughout its territorial sea, which extends 12 nautical miles (22 kilometers) from the na-

Oil spills harm marine wildlife. These volunteers gather penguins that have become soaked with oil from a spill in South Africa. Such animals must be cleaned if they are to survive.

A marine biologist, shown here, studies life in the ocean. A net is used to gather tiny animals and plantlike organisms.
Marine geologists study features of the ocean bottom. These scientists are examining and describing vertical samples of sediment called cores. Cores are drilled from beneath the sea floor.

Marine geologists study features of the ocean bottom. These scientists are examining and describing vertical samples of sediment called cores. Cores are drilled from beneath the sea floor.

The United States has not signed the Law of the Sea Convention. At the time this treaty was drafted, the U.S. government believed the treaty did not adequately protect private industries involved in deep-sea mining operations. However, the United States is working to resolve this difference, and it supports exclusive economic zones and many other provisions of the treaty.

CAREERS IN OCEANOGRAPHY

The ocean can be studied in many ways, and the science of oceanography includes several specialties. Physical oceanographers study waves, tides, currents, and the action of the ocean and the atmosphere on each other. Chemical oceanographers study the chemical reactions that occur in the ocean. Marine geologists and marine geophysicists analyze the form and composition of the sea floor, as well as the forces that shape the ocean floor. Marine geologists mainly study the sediments and surface features of the ocean bottom. Marine geophysicists deal with the deeper oceanic crust. Biological oceanographers and marine biologists study marine life, from microscopic bacteria to large marine mammals.

Ocean engineers design instruments to study the ocean, develop methods for obtaining minerals and other resources from the sea, and design structures for use in the ocean and on the sea floor.

To become an oceanographer, one needs a background in science and mathematics. Solid knowledge of at least one basic science, such as biology, chemistry, or geology, is required. Most oceanographers acquire detailed knowledge of oceans through graduate training.

An oceanographer may choose from several types of careers after completing training. Research jobs are available at colleges and universities, at oceanographic institutions, in government, and in industry laboratories. Colleges and universities also provide teaching jobs.

Some oceanographers go on long research expeditions or make deep-sea dives. Others formulate theories or interpret scientific observations. Oceanographers may also work with computers in an attempt to re-create, analyze, and predict ocean behavior. Dana Kester

Ocean Drilling Program is a scientific program that provides data on the composition of the Earth beneath the ocean floor. This information helps scientists understand the processes that have shaped the Earth. The program also provides information on the evolution of prehistoric life, the development of ice ages, and changes in the Earth's climate during the past 200 million years. Geologists use this information to learn how minerals form and where fossil fuels lie beneath the ocean.

The Ocean Drilling Program operates a special research drillship called the JOIDES Resolution. Teams of scientists from many nations participate on cruises that last about two months. During an expedition, the scientists remove cylindrical cores (samples) of sediment and hard rock from beneath the ocean floor. A drill pipe passes through a hole in the ship and extends beneath the sea floor. Within the pipe is a core barrel that brings up cores. Each core measures about 31 feet (9.4 meters) long and 2 1/2 inches (6.4 centimeters) wide. Many of the cores contain fossils and minerals that have accumulated over thousands or even millions of years. Scientists study them in a laboratory on board the ship to determine the age of the ocean floor and how it developed. Scientists can remove cores in water more than 27,000 feet (8,200 meters) deep.

The Ocean Drilling Program has continued the research begun by the Deep Sea Drilling Project. That project operated the drillship Glomar Challenger from 1968 to 1983. Among its many achievements, the Deep Sea Drilling Project confirmed the idea that the sea floor as spread away from underwater mountain ranges known as mid-ocean ridges as new sea floor has formed. Scientists believe that a giant land mass once nipped all the continents. Approximately 200 million years ago, the continents broke apart at the ocean ridges and gradually moved to their present positions.

Texas A&M University in College Station, Texas, operates the Ocean Drilling Program. The program receives funding from the United States National Science Foundation; from Australia, Canada, China, Japan, and South Korea; and from France, Germany, the United Kingdom, and 11 other countries in the European Science Foundation. Philip D. Rabinowitz

Ocelot, OH suh laht, is a medium-sized animal of the cat family. It is known as the leopard cat or tiger cat of America. It is 3 1/2 to 4 feet (107 to 120 centimeters) long including the tail, which is 15 inches (38 centimeters) long. The ocelot stands 16 to 18 inches (41 to 46 centimeters) high at the shoulder.

The ocelot lives in an area ranging from southeastern Arizona and southern Texas to Paraguay in South America. It spends most of its life on the ground, but it often hunts in forest trees and is an agile climber. It eats mice, wood rats, rabbits, snakes, lizards, birds, young deer, and monkeys. In the tropics, a favorite food is agoutis. If captured young, the ocelot can be tamed and makes an excellent pet.

The ground tint of ocelot fur varies greatly in different animals, ranging from reddish-yellow to smoky-pale. Black spots vary in size from dots on the legs and the feet to large shell-shaped spots on other parts of the body. The ocelot has a pink nose and large, translucent eyes.

Ocelots have been widely hunted for their fur, and their number has decreased sharply. Laws that prohibit
The ocelot lives in brushy and wooded areas from southwestern North America to central South America. Ocelots are agile climbers and often hunt small animals.

The hunting of ocelots have been hard to enforce.

Duane A. Schlitter

Scientific classification. The ocelot belongs to the cat family, Felidae. It is *Felis pardalis*.

See also Animal (picture: Animals of the tropical forests).

Ocher, *OH kuhr*, also spelled ochre, is a yellow to brownish-red type of earth. It is used to color inks, paints, and other substances. Heating the yellow variety produces burnt ocher, which has a rich red color. Ocher consists of iron oxide, clay, and sand. The state of Georgia has large ocher deposits.

George J. Danker

Ochs, ahks, Adolph Simon (1858-1933), rose from a job as a newsboy to become the publisher and guiding influence of The New York Times. He separated editorial comment from news in the *Times* and presented news free from prejudice. In 38 years, the daily circulation of the *Times* rose from 9,000 to 460,000. Ochs also founded the magazine *Current History*, and gave $500,000 toward publication of the Dictionary of American Biography.

Ochs began his career at 14 as an errand boy at the *Knoxville* (Tennessee) *Chronicle*. Later, he bought a half-interest in the *Chattanooga Times*, and made it one of the area’s strongest papers. He became manager of the *New York Times* in 1896, and gained controlling interest in 1900. He was born on March 12, 1858, in Cincinnati, Ohio. William McKeen

Ockham, William of. See William of Ockham.

Ocmulgee National Monument, *ohk MUHL gee*, is in central Georgia. It contains the most important prehistoric Indian mounds in the Southeast, including a restored council chamber. Ruins dating from 8000 B.C. were found there. The monument was established in 1934. For area, see National Park System (table: National monuments).

Critically reviewed by the National Park Service

O’Connell, Daniel (1775-1847), an Irish statesman, helped lead the struggle of Roman Catholics to gain political rights in the United Kingdom. This struggle resulted in the passing of the Catholic Emancipation Act of 1829. That act gave Catholic men the right to serve in the British Parliament and to hold most other public offices. Previously, Catholics were denied these rights in the primarily Protestant United Kingdom. The new law had a major effect in Ireland, then a part of the United Kingdom where most of the people were Catholics. O’Connell, called “the Liberator,” became the first Irish Catholic to win election to the British House of Commons. He served there from 1829 to 1847.

O’Connell was born on Aug. 6, 1775, in Cahirciveen, County Kerry. He became a lawyer in 1798. He formed the Catholic Association in 1823 to seek the political rights of Catholics. In Parliament, he played a key role in the passing of the Reform Act of 1832, which gave most middle class men the right to vote. He was arrested in 1843 for supporting a campaign demanding Ireland’s complete independence from the United Kingdom. In 1844, he was convicted of plotting against the government and spent 14 weeks in jail.

Thomas E. Hachey

O’Connor, Flannery (1925-1964), was an American author whose novels and stories are filled with characters who are physically deformed or emotionally or spiritually disturbed. Some are obsessed with religion and the possibility of their own damnation or salvation. But O’Connor’s books also contain humor, irony, and satire.

Mary Flannery O’Connor was born on March 25, 1925, in Savannah, Georgia. Her Southern heritage and her Roman Catholicism strongly influenced her writing. She suffered from poor health most of her life and could complete only a few works. They include two novels, *Wise Blood* (1952) and *The Violent Bear It Away* (1960). Her stories were collected in *A Good Man Is Hard to Find* (1955) and *Everything That Rises Must Converge*, published in 1963 after her death. The stories in these two collections are included in *Flannery O’Connor: The Complete Stories*, published in 1971. This collection won the 1972 National Book Award for fiction. *Mystery and Manners*, essays and lectures on literature and writing, was published in 1969. A collection of her letters called *The Habit of Being* was published in 1979.

Noel Polk

O’Connor, John Joseph Cardinal (1920-2000), was appointed a cardinal of the Roman Catholic Church by Pope John Paul II in 1985. The pope had named O’Connor archbishop of New York City in 1984. O’Connor received this appointment less than a year after becoming bishop of the diocese of Scranton, Pennsylvania.

O’Connor was born on Jan. 15, 1920, in Philadelphia. He was ordained a priest in 1945. O’Connor taught high school classes for seven years. He then joined the United States Navy and Marine Corps as a chaplain. In 1975, he was appointed Navy chief of chaplains. In 1979, he became an auxiliary bishop of the Military Ordinariate, a diocese that serves members of the U.S. armed forces. O’Connor served on a committee of bishops that drafted a pastoral letter condemning the nuclear arms race. The letter was approved by the National Conference of Catholic Bishops in 1983.

Kenneth Guenter

O’Connor, Sandra Day (1930- ), became the first woman to serve on the Supreme Court of the United States when she became an associate justice of the court in 1981. President Ronald Reagan appointed her to the court to fill the vacancy created that year by the retirement of Justice Potter Stewart.

As an associate justice, O’Connor has generally sided with conservative Supreme Court members. But she
has been sympathetic to liberal views on a small number of issues.

O'Connor was born in El Paso, Texas. She received a law degree from Stanford University in 1952. In 1965, she became an assistant attorney general of Arizona. In 1969, she was appointed to an unexpired term in the Arizona Senate. She won election to the state Senate in 1970, was reelected in 1972, and was Senate majority leader in 1973. O'Connor was elected a judge of a Maricopa County trial court in 1974. In 1979, the governor appointed her to the Arizona Court of Appeals, the second highest court in the state.

Octillo, oon kuh TEEL yoh, is a shrub that grows in the deserts of Mexico and Southwestern United States. It is also called candelwood, coachwhip, and vine cactus.

The octillo plant stands 6 to 25 feet (1.8 to 7.6 meters) tall, and has many long, spiny stems growing out from its base. After moderate to heavy rains, the stems bear leaves and bunches of scarlet flowers. But in the dry season, they stand bare as dry spiny sticks. Octillos make good hedges that are hard to pass through.

Scientific classification. Octillo is in the Fouquieria family, Fouquieriaceae. It is *F. splendens*. Philip W. Rundel

Octagon is a plane figure with eight sides. It is a type of polygon. The sides of an octagon meet at points called vertices to form eight interior angles. The interior angles of an octagon always add up to 1080°. A type of octagon called a regular octagon has equal sides and equal angles. The area of a regular octagon equals one-half the product of the perimeter and the apothem, the distance from the center of a regular polygon to the midpoint of one of its sides. Arthur F. Coxxford, Jr.

Octahedron is any solid figure with eight faces. It is a type of polyhedron (solid figure with many faces). The faces of an octahedron need not have the same shape. Some may be triangles and others another kind of polygon. A variety of octahedron called a regular octahedron is a convex polyhedron in which all of the eight faces are congruent to any given equilateral triangle. John K. Beem

Octane, AHK tayn, is any of 18 chemical compounds that consist of 8 carbon atoms and 18 hydrogen atoms. Octanes are among the main ingredients of gasolines. An octane called isooctane is used in a test mixture to determine how well a gasoline resists knocking (see Octane number). Gasolines that have a high octane number can prevent engine knock better than those with a lower octane number.

Octanes belong to a group of chemicals called hydrocarbons (see Hydrocarbon). All octanes are colorless liquids, all are highly flammable, and all have the same molecular formula, C₈H₁₈. However, they have different molecular structures and therefore different chemical and physical properties. For example, normal octane, also called n-octane, boils at 258.2° F. (125.7° C), but iso-octane boils at 210.6° F. (99.2° C). Geoffrey E. Dolbear

Octane number, AHK tayn, is a number that tells how well a motor fuel resists "knocking." Knocking occurs when the last of the fuel in an engine cylinder burns too soon or too fast. The octane number of a motor fuel is found by comparing the fuel's knocking tendency with that of reference fuels in a test engine. Each reference fuel is a blend of normal heptane (a knock-prone fuel) and isooctane (a knock-resistant fuel). Normal heptane has an octane number of zero, and isooctane a value of 100. A motor fuel has an octane number of 85 if it produces the same knock as a reference fuel made of 85 per cent isooctane and 15 per cent normal heptane. Most gasolines have octane numbers from 80 to 100. See also Gasoline. Kathleen C. Taylor

Octave, in music. See Music (Musical terms).

Octavia, ahk TAY vee uh (69?-11 B.C.), was the older half-sister of the Roman ruler Octavian, who became the emperor Augustus. In 27 B.C. Octavia married Octavian's co-ruler Mark Antony in 40 B.C. The marriage sealed a peace pact that ended a civil war between Octavian and Antony. Octavia bore Antony two daughters, Antonia the Elder and Antonia the Younger.

Antony treated Octavia badly. He had fallen in love with Cleopatra, queen of Egypt, before he married Octavia. In 37 B.C., Antony left Octavia to live with Cleopatra. He divorced Octavia in 32 B.C. Afterward, Octavia raised Antony's children by his first wife, Fulvia, in addition to her own children by Antony and her first husband, Marcellus. Octavia also raised Antony's children by Cleopatra after Antony and Cleopatra died in 30 B.C.

Octopuses are soft-bodied sea animals with eight long arms. Muscular suckers on the underside of each arm enable an octopus to cling tightly to rocks or prey. There are about 100 species of octopuses. The giant octopus, left, lives in the Pacific Ocean. The photos at the right show a cluster of transparent octopus eggs, top, and a newly hatched octopus.

Octopuses are soft-bodied sea animals with eight long arms. Muscular suckers on the underside of each arm enable an octopus to cling tightly to rocks or prey. There are about 100 species of octopuses. The giant octopus, left, lives in the Pacific Ocean. The photos at the right show a cluster of transparent octopus eggs, top, and a newly hatched octopus.

Octopus is a sea animal with a rounded body, large eyes, and eight long arms. There are about 100 species of octopuses. The best-known species inhabit rocky, sandy, or muddy bottoms in shallow parts of oceans throughout the world. Other octopuses live in deep waters.

Octopuses vary greatly in size. The largest species, the giant octopus of the Pacific Ocean, weighs as much as 110 pounds (50 kilograms). It measures more than 20 feet (6 meters) from the tip of one arm to the tip of another on the opposite side of the body. The smallest species, found in the Indian Ocean, weighs less than 1 ounce (28 grams) and measures about 1 inch (2.5 centimeters) from arm tip to arm tip.

Octopuses belong to a group of animals called mollusks. This group also includes clams, oysters, and snails. Like squids and cuttlefish, octopuses are mollusks that have no outside shell.

The body of an octopus is soft and boneless. A fleshy, muscular covering, called the mantle, surrounds the main part of the body, forming a cavity that encloses the gills. An octopus breathes by drawing water into the mantle cavity. The circulation of water provides oxygen for the gills. The mantle then contracts and forces the water out through a tube called the funnel or siphon. An octopus has three hearts. Two hearts are associated with the gills and are called gill hearts.

The two eyes of an octopus are on each side of the head. They are similar in structure to the eyes of human beings and provide good vision.

Eight arms extend from the head of an octopus. At their base, the arms are united by a membrane web. The underside of each arm is lined with round, muscular suckers. An octopus uses its arms and suckers to move along the ocean bottom and to capture the small
animals that it eats. The suckers can provide enormous suction, enabling the octopus to attach firmly to rocks. If an octopus loses an arm, a new one grows in its place. An octopus's mouth is a beaklike structure located beneath the head at the base of the arms.

The life of an octopus. Octopuses feed chiefly on crabs, clams, and snails. Many species also eat other octopuses. Certain octopuses make a hole in the shell of their prey and then inject a poison that paralyzes the animals.

Many sea animals—especially seals, whales, and certain fish—prey on octopuses. An octopus has various means of avoiding predators. It can swim quickly backward by forcing a powerful jet of water through its funnel. The octopus may conceal itself by discharging a cloud of ink fluid. In some cases, the shape of the ink cloud resembles the octopus and thus acts as a decoy.

An octopus also can escape danger by rapidly changing colors. Its skin contains cells called chromatophores, each of which contains a single-colored pigment. When the octopus is excited, these cells contract or expand, producing a color change that can startle a predator or enable the octopus to blend with the surroundings.

Octopuses reproduce sexually. The female octopus can lay more than 100,000 eggs. She cares for the eggs until they hatch into tiny, immature octopuses. The young swim at or near the surface of the water for several weeks as part of plankton (see Plankton). Many of the young are eaten by fish and other marine animals. The remaining young drop to the ocean bottom and develop into adult octopuses. Some species lay relatively large eggs. The young of these species live on the ocean bottom immediately after hatching.

Octopuses have short lives. Many live one year or less. The largest species live about three years.

Octopuses and people. Most octopuses are not regarded as dangerous to human beings. However, octopuses sometimes bite, so caution is necessary in handling them. In some countries, octopus is an important food. There are octopus fisheries in many parts of the world, most notably off Japan, in the Mediterranean, and off the northwest coast of Africa.

Scientific classification. Octopuses make up the order Octopoda in the class Cephalopoda and the phylum Mollusca. Many species belong to the genus Octopus. Brian Hartwick

Odd Fellows, Independent Order of, is one of the most important fraternal and benevolent orders in the United States. The order was founded in England. The date of its founding is not known, but Odd Fellows' groups probably existed in the early 1700s. The members founded a system of benefits and helped one another in time of misfortune. Branches called lodges grew up in the various English cities, but each branch refused to admit the superior rank of any other. Adjustments were finally made, and in 1814, the Manchester Unity of the Independent Order of Odd Fellows was organized. Today, this organization has branches in various countries, but it has no connection with the order in the United States.

The American order. In 1819, the Washington Lodge of Odd Fellows was organized in Baltimore. The next year, Washington Lodge became a subordinate lodge in the Manchester Unity. Other American lodges were established later and assumed a like position.

In 1843, the American lodges separated themselves from the parent order in England. The United States grand lodge became the head of the order in America and reserved for itself the right to found new lodges in Europe. The Canadian branch operated under a separate charter until 1852. In that year, the society in Canada was merged with the grand lodge of the United States. The Order of Odd Fellows in the United States has a membership of 500,000.

Purpose and organization. The chief purpose of the Order of Odd Fellows is to give aid, assistance, and comfort to its members and their families. It also does local charitable and volunteer work. It has its own system of rites and passwords. The three links in its symbol represent friendship, love, and truth.

A local lodge can confer three degrees of membership upon an Odd Fellow. When a member has reached the highest of these three degrees, he is ready for membership in an encampment. The encampment also has three degrees of membership, the Patriarchal, the Golden Rule, and the Royal Purple. The Patriarchal is an English degree. Since 1884, there has also been a military or uniformed degree called the Patriarchs Militant.

The Rebekah lodges in Odd Fellows are chiefly for women, although some men belong. Rebekah assemblies were organized in 1851, and they continue to provide much volunteer work for the order. The headquarters of the order are at 422 Trade Street, Winston Salem, NC 27101.

Critically reviewed by the Independent Order of Odd Fellows

Ode, ode, is a poem of moderate length that usually expresses exalted praise. Greek dramatists wrote choral odes that had three parts. Two parts, a strophe and an antistrophe, had identical meter. The third part, called an epode, had a contrasting meter. Pindar, of ancient Greece, wrote odes in praise of athletic heroes. He used the strophic form, which came to be called Pindaric (see Pindari). Horace, of ancient Rome, wrote odes made up of uniform stanzas, called stanzaic form.

English poetry, from the time of Ben Jonson, included a variety of Pindaric odes, stanzaic odes, and irregular odes, or those with no particular stanza structure. John Dryden wrote two irregular odes in praise of St. Cecilia. "Ode to Evening," by William Collins, is a notable stanzaic ode. The great irregular and stanzaic odes of the 1800s include William Wordsworth's "Ode: Intimations of Immortality," Percy Bysshe Shelley's "Ode to the West Wind," John Keats's "Ode on a Grecian Urn," and Alfred, Lord Tennyson's "Ode on the Death of the Duke of Wellington."

'Oder River, OH duhr,' is an important waterway in central Europe. It is about 530 miles (855 kilometers) long and drains about 46,000 square miles (119,000 square kilometers).

The Oder, also called Odra, rises in the Sudeten Mountains of the Czech Republic. It then flows northward across western Poland where it is joined by the Neisse (Nysa) River—officially Lusatizer Neisse (Nysa Łużycka). The joined rivers form most of the boundary between Poland and Germany. The Oder empties into the Baltic Sea by way of the Stettin Lagoon (see Poland [terrain map]). Oceangoing vessels use the Polish port of Szczecin south of the lagoon. Other major cities on the Oder include Frankfurt in Germany, the Polish cities of Wrocław and Opole, and Ostrava in the Czech Republic.

The Oder's tributaries include the Warta (Warthe) River. The Warta links the Oder with the Vistula River in Poland by the Noteć (Netze) River and a canal. Canals also link the Oder with the Polish industrial city of Gliwice and the Havel and Spree rivers in Germany.

The Oder-Neisse boundary between Poland and East Germany was established after World War II ended in 1945. East Germany recognized this boundary in 1950. West Germany opposed the boundary until 1970, when it signed treaties with both Poland and the Soviet Union confirming the boundary. East Germany and West Germany unified in 1990.

Leszek A. Kosinski

Odessa, oh DEHS oh (pop. 1,106,000), is a seaport city in Ukraine. It lies on the southwestern coast, near the Romanian border. Odessa is on the Black Sea, 32 miles (51 kilometers) southwest of the mouth of the Dnepr River. For location, see Ukraine (political map).

Odessa is one of Ukraine's industrial centers. Its refineries produce large amounts of petroleum products. Factories make machinery, automobiles, airplanes, and motion-picture equipment. Odessa is an important transfer point for rail and ocean transportation. The city is also known for its health resorts.

Odessa is built in a circular shape and slopes down toward the city's harbor. A long, spectacular staircase leads up from the harbor. The staircase is called the Potemkin Steps in memory of the crew of the ship Potemkin, who mutinied in Odessa during the Russian Revolution of 1905.

Historians are not sure when the first settlement was established on the site where Odessa now stands. The area was conquered by the Tatars in the 1200s, followed by the Lithuanians in the 1300s and the Ottomans in the 1500s. Russia gained control of the site in 1792 and built a port and a fortress there. In 1795, Russia named the city Odessa. In 1844, Odessa became part of the Ukrainian Soviet Socialist Republic of the Soviet Union. The Soviet Union had been formed under Russia's leadership in 1922. In 1991, following an upheaval in the Soviet Union, the Ukrainian republic declared itself an independent nation. In December of that year, the Soviet Union was dissolved.

Odessas, oh DEHTS, Clifford (1906-1963), an American dramatist, is best known for his plays of social conflict written during the 1930s. His most successful works were presented by the famous Group Theatre.

Odets' one-act play Waiting for Lefty (1935) is about a taxi drivers' strike. It ranks among the most important of the many plays written in the 1930s that deal with the struggle of the working class. Odets' Awake and Sing! (1935) is less propagandistic than Waiting for Lefty. It tells the story of a poor Jewish family in the Bronx during the Great Depression. Odets also wrote Paradise Lost (1935), Golden Boy (1937), Night Music (1940), The Big Knife (1948), and The Country Girl (1950).

Odets was born in Philadelphia. He helped form the Group Theatre in 1931. He was a film scriptwriter from 1936 until shortly before his death.

Frank R. Cunningham

Odin, oh DIHN, was the chief god in Norse mythology. In German, he is called Wotan (pronounced WOH tuhn). Odin became the ruler of the universe after he and his two brothers, Ve and Vili, killed the frost giant Ymir, the first living being. From Ymir's huge body, they made Midgard, the earth; and began to build Asgard, the dwelling place of the gods.

Valhalla was Odin's home in Asgard. There he feasted with the souls of heroes who had died in battle. Odin, a fearless fighter, carried a spear as his weapon, and rode an eight-legged horse called Sleipnir. He inspired ferocious human warriors called Berserkers who fought recklessly without armor and felt no wounds.

Odin was the wisest god. He gave up one eye for the right to drink from the spring of wisdom, guarded by Mimir, a supernaturally wise creature. Odin was also known for his magic powers. By woundng and hanging himself from a tree, he acquired the power of spells called runes. They let him predict the future, change his shape at will, and visit the underworld. Odin's sons included Thor, the god of thunder and lightning, and Balder, the god of goodness. According to Norse myths, Odin will lead the gods against the evil giants at Ragnarok, the battle that will destroy the world. He will be eaten by Fenrir, a ferocious wolf.

The Anglo-Saxons' name for Odin was Woden. It was the source of the word Wednesday.

Carl Lindahl

Odoacer, oh doh AH yuhr (A.D. 437-493), was the Germanic leader who overthrew the last emperor of Rome in the West, ending the West Roman Empire.

Odoacer was probably born near the Danube River in what is now Germany. He joined the West Roman army and became a leader of barbarian troops serving the Romans. In 476, when the Roman government refused to give his troops land for settlement, Odoacer led them in a revolt. Odoacer deposed the West Roman emperor, Romulus Augustulus, and became the first barbarian king of Italy. Historians consider this event the end of the West Roman Empire. But for years, barbarian generals had been its real rulers. The emperors were symbolic rulers.

Odoacer ruled independently, though he pretended to serve Zeno, the East Roman emperor. Zeno never recognized Odoacer as ruler of Italy. In 488, Zeno sent the Ostrogoth king Theodoric to attack Odoacer. Odoacer retreated to Ravenna, where he surrendered in 493 and was executed (see Theodoric).

Odometer. See Speedometer.

Odyssey, AHD uh see, an epic poem, is perhaps the most influential and most popular work in ancient Greek literature. The Odyssey ranks among the greatest adven-
ture stories in literature. It became a model for many later adventure stories.

According to tradition, the *Odyssey* was composed by the Greek poet Homer, probably in the 700's B.C. The central character is Odysseus (Ulysses in Latin), the king of Ithaca. The poem describes Odysseus's journey home after fighting for Greece against the city of Troy in the Trojan War. The author told about this war in the *Iliad*, another great epic poem. See Homer.

The *Odyssey* consists of 24 books (sections). The story takes place over about 10 years. The tale begins after much of the action has already occurred. This device of starting a story in the middle and returning to the start is called *in medias res*. Many later writers used it.

**The Odyssey begins** on the island of Ogygia, where Odysseus has been the prisoner of the sea nymph Calypso for seven years. At a council of the gods on Mount Olympus, Zeus decides the time has come for Odysseus to return to his wife, Penelope, in Ithaca.

The scene then changes to Odysseus's palace in Ithaca, where a group of unruly young noblemen has settled. The noblemen want Penelope to assume that her husband is dead. They demand that she marry one of them and thus choose a new king of Ithaca. Odysseus's son, Telemachus, resents the noblemen. The goddess Athena suggests that he go on a journey to seek news of his father. Telemachus agrees and leaves Ithaca.

The tale next returns to Odysseus's adventures. The god Hermes makes Calypso release Odysseus. Odysseus sails away on a raft, but the sea god Poseidon causes a storm and he is shipwrecked on the island of the Phaeacians, Nausicaa, the beautiful daughter of the Phaeacian king, discovers him.

**Odysseus describes his wanderings** since the Trojan War while being entertained by the Phaeacians. He tells of his visit to the land of the lotus-eaters, whose magic food makes people forget their homeland. Some of his men who ate the food wanted to stay with the lotus-eaters, but Odysseus forced them to leave with him. Odysseus and his men then sailed to an island where they were captured by Polyphemus, a one-eyed giant called a Cyclops. They escaped after blinding the Cyclops with a heated stake. But the Cyclops prayed to his father, Poseidon, to avenge him by making Odysseus's homecoming as difficult as possible.

After more adventures, the ship carrying Odysseus and his men landed on the island of the enchantress Circe. Circe changed Odysseus's men into pigs and made Odysseus her lover. She told Odysseus that to get home, he must visit the underworld to consult the prophet Teiresias. In the underworld, Odysseus saw the ghosts of his mother and of Trojan War heroes. He also witnessed the punishment of sinners.

Teiresias warned Odysseus of the dangers awaiting him, and Circe told him how to sail past the sea monsters Scylla and Charybdis. Circe also warned him about the Sirens, sea nymphs who use their beautiful singing to lure sailors to death on a magic island. Odysseus's ship sailed past these dangers and seemed ready to reach Ithaca without further trouble. But some of Odysseus's men stole and ate the sacred cattle of the sun on the island of Thrinacian. As punishment, the ship was destroyed by a thunderbolt and the men drowned. Odysseus was washed up on Ogygia, where the story began.

**Odysseus encounters the Sirens** during his voyage home. The Sirens, part bird and part woman, lured seamen to their death with beautiful singing. Odysseus had himself tied to the mast so he could safely enjoy the singing.

**Odysseus returns home.** After Odysseus finishes his story, the Phaeacians take him to Ithaca. Athena tells him of the noblemen in his palace and advises him to return home in disguise. Odysseus goes to his palace disguised as a beggar. Penelope has agreed to marry the man who can string Odysseus's huge bow and shoot an arrow through 12 axes. Odysseus wins the contest, kills the noblemen, and is reunited with Penelope.

**The Odyssey as literature.** The *Odyssey* is a skillfully told adventure story. The story combines realistic accounts of life in ancient Greece and elements of historical events with fairy tales about imaginary lands.

The work also contains skillful characterization. Odysseus represents the model of a man of courage and determination. In spite of many setbacks, he never abandons his goal of returning home. But he has other human traits that keep him from being only a symbol. He enjoys life, even while struggling to get home. He is restless, clever, and even tricky and is able to invent lies easily. In fact, some later Greek dramatists made Odysseus a symbol of deceit. Penelope stands for the faithful, loving wife. Telemachus symbolizes the youth who matures by facing a difficult challenge. The travels of Odysseus and Telemachus may represent the human journey through life and the search for self-fulfillment and self-knowledge.

**Additional resources**
Oedipus, EHD uh puhs, was a king of Thebes in Greek mythology. Many ancient authors wrote different versions of the story of Oedipus. The following version is based largely on Oedipus Rex, a tragedy by the Greek playwright Sophocles.

The oracle (prophet) of Delphi told King Laius of Thebes that a son born to his wife, Queen Jocasta, would kill him (see Delphi). After Jocasta gave birth to a son, Laius ordered the baby taken to a mountain and left to die. However, a shepherd rescued the child and brought him to King Polybus of Corinth. Polybus adopted the boy and named him Oedipus.

Oedipus grew up in Corinth. As a young man, he learned from the oracle that he would kill his father and marry his mother. Believing that Polybus was his father, Oedipus tried to avoid the prophecy by fleeing Corinth. On the road to Thebes, he quarreled with a man and killed him. The stranger was King Laius.

Near Thebes, Oedipus encountered a monster called the Sphinx. She had a woman's head, a lion's body, and a bird's wings. The Sphinx killed everyone who could not solve this riddle: What has one voice and becomes four-footed, two-footed, and three-footed? The Sphinx asked Oedipus the riddle, which no one had solved. He answered: Man, who crawls on all fours as a baby, then walks on two legs, and finally needs a cane in old age. The Sphinx killed herself because Oedipus had solved the riddle. Oedipus was rewarded by being made king of Thebes. He married Jocasta, the widowed queen.

Several years later, a plague struck Thebes. The oracle said it would end when the murderer of Laius had been driven from Thebes. Oedipus investigated the murder and came to realize that Laius was the man he had killed on the road to Thebes. He then discovered that Laius was his father and Jocasta his mother. Oedipus blinded himself, and Jocasta hanged herself. Oedipus was banished from Thebes. He died at Colonus, near Athens. John Hamilton

See also Mythology (Levi-Strauss's theory).

Oedipus complex, EHD uh puhs, a concept used in psychoanalysis, is a child's unconscious desire for the exclusive love of the parent of the opposite sex. This desire includes jealousy toward the parent of the same sex and the unconscious wish for that parent's death.

The term Oedipus complex was first used by the Austrian physician Sigmund Freud. It comes from the myth of Oedipus, a Greek hero who unknowingly killed his father and married his mother (see Oedipus). Freud used the term to describe the unconscious feelings of children of both sexes toward their parents. However, later researchers used the term Electra complex for the complex in girls. According to Greek legend, a woman named Electra helped plan the murder of her mother.

Freud believed that the Oedipus complex is a normal part of human psychological growth. The Oedipal phase of development is commonly considered to last from the age of 2 1/2 to 6. During this period, children experience intense feelings—love and hate, yearning and jealousy, fear and anger—that produce emotional conflicts. Most people outgrow the Oedipal phase, but some mentally ill individuals have a strong Oedipus complex as adults. According to Freud, the principal reason for the weakening of the complex in boys is the fear of punishment from the father.

Freud thought that all peoples experience the Oedipus complex. But many anthropologists and researchers in psychoanalysis doubt that the complex exists in certain non-Western societies. They believe it develops as a result of a person's social environment and does not occur in everyone. Nancy C. Andreasen

Oersted, **UK stehd. Hans Christian** (1777-1851), a Danish physicist and chemist, laid the foundation for the science of electromagnetism (see Electromagnetism). In 1820, he noticed that the needle of a compass wavered every time he put it near a wire carrying a current. He had discovered that every conductor carrying an electric current is surrounded by a magnetic field. Oersted is also credited with producing the first aluminum, in 1825 (see Aluminum [The first aluminum]). He wrote Spirit of Nature (1850). Oersted was born in Rudkøbing, Denmark. Richard G. Olson

**Offenbach** (**AW fuhn bahk. Jacques, zhahakh** (1819-1880), a French composer, created the French style of operetta. His operettas are humorous, witty, and satirical. He enjoyed poking fun at the politics and society of his day, and quoting familiar themes from other compositions (especially operas). Offenbach's success internationally helped to establish operetta as an accepted musical form and led to the development of musicals in the United States in the 1900s.

Many of Offenbach's operettas are called **opéras bouffes** (comic or light operas). He eventually completed more than 90 works for the stage. His first success was Orpheus in the Underworld (1858). His most popular compositions appeared in the 1860s. They include La Belle Hélène (1864), La Vie Parisienne (1866), La Grande-Duchesse de Gérolstein (1867), and La Périchole (1868).

In 1877, he began his most famous work, the opera The Tales of Hoffmann, which was unfinished at his death. See Operetta.

**Oedipus**, a hero in Greek mythology, solved the riddle of the Sphinx. The Thebans rewarded him by making him king.
Offenbach was born in Cologne, Germany. He moved to Paris in 1833 to study the cello, and for many years had a successful career as a cellist. He became a conductor at the Théâtre-Français in 1850. In 1855, he founded the Bouffes-Parisiens, a theatrical company that staged many of his operettas. Offenbach became a French citizen in 1860. Katherine K. Preston

**Office of...** See articles on offices listed under their key word, as in Management and Budget, Office of.

**Office work** is the process of recording, storing, and distributing the information needed to operate a business. The managers of the business use this information to make administrative decisions.

Millions of people in industrialized countries are employed as office workers. They include bookkeepers and accounting technicians, clerk-typists, secretaries, and word-processing technicians. Office workers do not include people involved in such activities as buying, selling, or management.

An office may receive information by telecommunication, by mail, or by computer. An office worker must have skill in language and arithmetic to handle this and other business information properly. Almost all office jobs require at least a high school education. Many employers prefer people who have taken courses beyond the high school level. A person can get such advanced training at a community college, junior college, or business or vocational school. This training may include instruction in operating calculators, copying machines, microfilm equipment, and personal computers.

An office requires a staff of managers to plan and direct work. As a business grows, so does the amount of information that must be handled by its office workers. The managers coordinate the activities of these employees so that accurate records can be kept concerning correspondence, inventory, payroll, sales, and taxes.

**Recording information.** Business information may be recorded by hand or by machine. Some handwritten information may be used in the form in which it is recorded. For example, a secretary may take a telephone message for someone who is out of the office. Such information does not have to undergo further processing before it can be used. Other types of information may be recorded by hand before being processed through a machine. For example, a stenographer takes notes in shorthand and then types letters from the notes.

Information can also be recorded directly into a machine. A manager may dictate a letter into a dictating machine and have a secretary transcribe the message into a personal computer.

Today, many secretaries use personal computers equipped with word-processing software to do the work that otherwise would be done with typewriters. Some of these computers are small enough to be held in the worker’s lap. Personal computers have a keyboard similar to that of a typewriter. The computer may be linked to a printer that can quickly produce copies of the original material.

Many office workers still use electric, electronic, or word-processing typewriters. Electric typewriters have a motor to provide power, and so the typist only needs to touch the keys lightly. Electronic typewriters can automatically perform such functions as setting margins and underlining. With word-processing typewriters, the operator enters the material onto a magnetic card, tape, or disk. The word processor can then print copies of the material.

Bookkeepers can also record information directly into a machine. For example, they may enter data into a computer by using spreadsheet software. With this software, the user can enter numbers and other information into special boxes displayed on the computer screen. The computer then uses the data to tabulate and print financial reports automatically.

**Storing information.** A business firm stores information to provide a record of its transactions. Many companies use computers and other high-capacity data-processing equipment to store information. A worker may enter information into a computer by using a keyboard. The signals that make up the information are sent to the computer’s memory for storage. A computer can also receive information from an optical scanner, a machine that “reads” handwritten or printed material directly off a page.

Another method of storing information, called micrographics, records printed material photographically and reduces the image. It saves filing space and keeps records in good condition for a long time. Micrographics uses filmstrips called microfilm or sheets of film called microfiche. About 3,000 business letters can be photographed on a strip of microfilm 16 millimeters (3/4 inch) wide and 100 feet (30 meters) long. The strip can be wound up in a roll that takes only about 16 cubic inches (262 cubic centimeters) of space. About 400 business letters can be photographed on a sheet of microfiche that measures 105 by 148 millimeters (4 1/2 by 5 7/8 inches). A form of microfiche called ultratrace can display over 3,000 business letters. Microfilm and microfiche are read using machines that enlarge the images.

**Distributing information.** Messenger service ranks as one of the oldest methods of distributing information within an office. Messengers visit the various departments of a company at regular times daily to pick up and deliver communications.

Information to be distributed to many people in an office may be duplicated on paper with a copying machine. Copying machines make copies quickly and inexpensively, often through a process called xerography. In addition, a computer can quickly find any information in its memory and then print copies.

Messages also can be transmitted within an office—or around the world—electronically. For example, workers can exchange information over computer networks by e-mail, also called electronic mail. E-mail can be sent to many individuals simultaneously.

**Officer.** See Rank, Military; Reserve Officers Training Corps.
Offset is a printing process in which the printing is done first on the rubber surface of a rotating cylinder. The impression is then transferred to paper by the pressure of other cylinders. The term offset describes the transfer, or offsetting, of the ink from a printing plate to the rubber and then to the paper.

All ordinary offset printing is done from the metal surfaces of lithographic plates (see Lithography). The material to be printed is transferred onto the plates through a special photographic process. The plates are chemically treated so that only the traced design of the print will take up the ink. But the offset process is used for other methods also. Some printing is done from ordinary type and cuts, some from thin plastic relief or letterpress plates, some from gelatin surfaces, and some from intaglio plates, which are metal sheets that carry the ink in sunken lines.

Offset lithography is usually done on a press having three cylinders. A lithographic plate is wrapped around the first cylinder. This plate is a sheet of aluminum or zinc about as thick as heavy paper. The plate prints on a second cylinder, which is covered by a rubber blanket. The impression on the rubber is then printed on the paper carried by the third cylinder. The third cylinder is equipped with steel fingers, called grippers, to hold the paper in position while it is squeezed against the rubber surface. Three-cylinder presses of this type can turn out 10,000 to 12,000 impressions an hour.

These cylinders are almost hidden while the press is in operation. They are covered by a great number of rollers which supply the lithographic plate with ink and water. The cylinders are also concealed by the mechanism for feeding and removing the sheets of paper.

Offset has several advantages over other types of printing. The elastic rubber transfers the impression to a rough surface as easily as to a smooth one. This makes it possible to print on rough paper, as well as on tin, celluloid, and other substances. Another advantage of offset is that the rubber on the cylinder fits easily to uneven surfaces. This reduces the time workers must spend preparing the presses for printing.

Offset was developed in the early 1900s in the United States as a method of printing tin sheets for making cans and boxes. It has recently been applied to almost every class of printing, from the cheapest to the most expensive. Offset has replaced the older forms of lithography in which the impression was made directly on the paper from stone or metal plates. An offset press can turn out bank notes, letterheads, magazine covers, mailing catalogs, newspapers, posters, and stock certificates. In the United States, the offset press is used to print most daily newspapers. Offset is combined with rotogravure, another printing process, to make colored illustrations that are clear and delicate. It is also used for facsimile reproduction of old books.

Offset is still being improved and applied to new purposes. The wearing qualities of the lithographic plates are being improved. Offset presses have been designed to print on a web (continuous sheet on a spool) of paper. The paper on this web press is passed between two rollers covered with rubber blankets, printing on both sides at the same time.

See also Intaglio; Printing; Photogravure and photolithography.

**Offutt Air Force Base**, Nebraska, is headquarters of the United States Strategic Command (USSTRATCOM), an interservice command for nuclear offensive forces. In a nuclear war, USSTRATCOM would control all U.S. long-range nuclear weapons, including submarine-launched missiles. USSTRATCOM was created in 1992.

The base covers 4,044 acres (1,637 hectares) south of Omaha. On this site, the U.S. Army established Fort Crook in 1891. In 1921, the Army completed construction of an airfield there. In 1924, the airfield was named Offutt Field after First Lieutenant Jarvis J. Offutt, a pilot killed in World War I. In 1946, the Army Air Forces gave the name Offutt Field to all of Fort Crook. In 1948, the newly created U.S. Air Force acquired Offutt Field and named it Offutt Air Force Base. Offutt served as the headquarters of the Strategic Air Command from 1948
O'Higgins, Bernardo 1778-1842, was the chief liberator of Chile and its first leader after independence. He headed the nation from 1817 to 1823.

In 1814, O'Higgins became commander in chief of rebel forces fighting to gain Chilean independence from Spain. In October, the Spaniards defeated the rebels at the Battle of Rancagua, and O'Higgins fled with his army to Argentina. There, he joined forces with the Argentine general José de San Martín. In 1817, the combined armies crossed the Andes Mountains and defeated the Spaniards at Chacabuco, near Santiago. O'Higgins was then named supreme director of Chile. O'Higgins and San Martín won a final victory over the Spanish forces in 1818 at the Maipo River.

O'Higgins backed a number of reforms for Chile but met with strong opposition from aristocrats, provincial chiefs, and the Roman Catholic Church. Lack of support for his policies caused him to resign in 1823.

Bernardo O'Higgins Riquelme was born on Aug. 20, 1778, in Chillán, Chile. His Irish-born father, Ambrosio O'Higgins, was a colonial official in the service of Spain.

Ohio

The Buckeye State

Ohio is one of the leading industrial states in the United States. Its industries produce motor vehicles, machine parts, metal products, processed foods, steel, and many other products. Ohio ranks 7th among the states in population, though it is 35th in area. Columbus is Ohio's largest city and the state capital. Cleveland, the state's chief industrial center, is Ohio's largest metropolitan area.

Ohio took its name from the Iroquois Indian word meaning something great. The Iroquois used the word for the Ohio River, which forms the state's southeastern and southern borders. Ohio is called the Buckeye State because of the buckeye trees that once grew plentifully on its hills and plains. Pioneers cut down many of the buckeyes to build log cabins.

In 1803, Ohio became the first state to be carved out of the Northwest Territory. Ohio later served as an important link to the West as canals, railways, and roads crossed the state. It was called the Gateway State.

Several natural advantages helped Ohio become a great manufacturing state. Ohio has an abundant supply of water and large deposits of coal, salt, and other important minerals. Its central location, near raw materials and major markets, has helped attract many large industries. Ohio ranks high among the states in the manufacture of motor vehicles and motor vehicle parts, industrial machinery, food products, and steel.

But manufacturing is only part of the Ohio economy. A majority of the state's workers are employed in service industries, which include such activities as education, health care, and trade. Cleveland and Columbus are important financial centers of the United States. In addition, Cleveland is among the nation's leading health care centers and Columbus is an important distribution center. Cincinnati, Ohio's third-largest city, is also an important center of manufacturing and trade.

Farmland covers about half of Ohio. Soil in the Till Plains area of western Ohio is especially fertile. Ohio is a major producer of corn and soybeans.

Ohio claims the title of the Mother of Presidents.
Interesting facts about Ohio

The first electric traffic signal lights on record were invented by James Hoge of Cleveland. They were installed in Cleveland on Aug. 5, 1914, at Euclid Avenue and East 105th Street by the American Traffic Signal Company. Brackets on poles at each corner held red or green lights 15 feet (4.5 meters) above the street. When the lights were about to change, a bell rang to warn the motorists.

The first public weather forecasting service in the United States was started in Cincinnati. Cleveland Abbe, the director of the Cincinnati Observatory, issued the first of his daily statements of “probabilities” on Sept. 1, 1869. He predicted prevailing easterly and southerly winds for September 2.

The first book matches were manufactured by the Diamond Match Company at its factory in Barberton in 1896. The company had obtained the patent of book matches from the man who invented them, Joshua Pusey, a Philadelphia attorney. The patent date, Sept. 27, 1892, appeared on Diamond matchbooks for years.

The oldest known watercraft in North America is a dugout canoe built about 1600 B.C. It was found in 1977 in a peat bog at the head of the Vermilion River in Ashland County. The canoe is now on display at the Cleveland Museum of Natural History.

Downtown Cleveland includes Public Square, with the 46-story Standard Oil Building rising in the background.

Seven Presidents of the United States were born in Ohio, more than in any other state except Virginia. In historical order, the Presidents born in Ohio were Ulysses S. Grant, Rutherford B. Hayes, James A. Garfield, Benjamin Harrison, William McKinley, William Howard Taft, and Warren G. Harding. William Henry Harrison was living in Ohio when he became President of the United States.

Two of the nation’s most famous astronauts were born in Ohio. Neil A. Armstrong, the first person to set foot on the moon, was born in Auglaize County near Wapakoneta. John H. Glenn, Jr., the first American astronaut to orbit the earth, was born in Cambridge and grew up in New Concord. He was elected to the United States Senate from Ohio in 1974.

Many famous inventors also came from Ohio. Thomas A. Edison, the wizard of electricity, developed his scientific curiosity as a small boy in Milan. Orville and Wilbur Wright made test flights in their first power-driven airplane from a field near Dayton. Charles F. Kettering of Dayton developed a self-starter for automobiles. The aluminum-refining process was discovered by Charles M. Hall of Oberlin.

An aircraft manufacturing plant in Columbus produces bomber parts for the United States Air Force. Ohio ranks among the leading manufacturing states.
Ohio in brief

Symbols of Ohio
The state flag was adopted in 1902. The triangle represents Ohio’s hills and valleys, and the stripes symbolize roads and waterways. The 17 stars stand for Ohio as the 17th state. The white circle with a red center represents Ohio’s initial and the buckeye nut. The seal, adopted in 1967, bears a sheaf of wheat and a bundle of 17 arrows. The sun rising over mountains shows that Ohio was the first state west of the Allegheny Mountains.

State flag
State seal

General information
Statehood: March 1, 1803, the 17th state.
State abbreviations: O. (traditional); OH (postal).
State motto: With God, All Things Are Possible.
State song: "Beautiful Ohio." Words by Ballard MacDonald, music by Mary Earl.

Land and climate
Area: 41,328 sq. mi. (107,040 km²), including 376 sq. mi. (973 km²) of inland water but excluding 3,499 sq. mi. (9,063 km²) of Great Lakes water.
Elevation: Highest—Campbell Hill in Logan County, 1,530 ft. (472 m) above sea level. Lowest—433 ft. (132 m) above sea level along the Ohio River in Hamilton County.
Record high temperature: 113 °F (45 °C) near Gallipolis on July 21, 1934.
Record low temperature: −39 °F (−39 °C) at Milligan, near New Lexington, on Feb. 10, 1899.
Average July temperature: 73 °F (23 °C).
Average January temperature: 28 °F (−2 °C).
Average yearly precipitation: 38 in. (97 cm).

Important dates
The first permanent white settlement in Ohio was established at Marietta.
The Ohio and Erie Canal was completed.

1803
1832
1788
C. 1670
Ohio became the 17th state on March 1.
La Salle probably became the first white person to explore the Ohio region.
**Ohio**

- **State bird**: Cardinal
- **State flower**: Scarlet carnation
- **State tree**: Buckeye

### People

**Population**: 11,353,140 (2000 census)

**Rank among the states**: 7th

**Density**: 275 per mi² (106 per km²), U.S. average 78 per mi² (30 per km²)

**Distribution**: 74 percent urban, 26 percent rural

**Largest cities in Ohio**

- Columbus: 711,470
- Cleveland: 478,403
- Cincinnati: 331,285
- Toledo: 313,619
- Akron: 217,074
- Dayton: 166,179

### Sources of information

- **For information about tourism**, write to: Ohio Division of Travel and Tourism, Vern Rife Center, P.O. Box 1001, Columbus, OH 43216-1001. The Web site at www.ohiotourism.com also provides information.

- **For information on the economy**, write to: Department of Development, 77 S. High Street, P.O. Box 1001, Columbus, OH 43216-1001.

**The state's official Web site** at www.state.oh.us also provides a gateway to much information on Ohio's economy, government, and history.

### Events

- **1914**: The Miami River Valley flood-control project was completed.
- **1922**: Ohio adopted a state income tax.
- **1935**: Ohio passed the Conservancy Act after floods in 1913.
- **1971**: The Ohio Turnpike was opened to traffic.
- **1993**: Voters approved a $200 million state park and recreation area improvement project.
People

Population. The 2000 United States census reported that Ohio had 11,353,140 people. The state's population had increased by nearly 5 percent over the 1990 census figure, 10,847,115. According to the 2000 United States census, Ohio ranks 7th in population among the 50 states.

About 85 percent of Ohio's people live in the state's metropolitan areas. About half of the people live in the three largest metropolitan areas of Ohio—Cincinnati, Cleveland, and Columbus.

In all, Ohio has 15 metropolitan areas. Ten of these areas lie entirely within the state. Five metropolitan areas are partly in Ohio and partly in one or more of the bordering states of Indiana, Kentucky, and West Virginia (see Metropolitan area). For the names and populations of the metropolitan areas, see the Index to the political map of Ohio.

Columbus, with a population of 711,470, ranks as the largest city in Ohio. Five other cities in the state have populations of 100,000 or more. These cities are Cleveland, Cincinnati, Toledo, Akron, and Dayton. For more information on Ohio's cities, see the articles listed in the Related articles at the end of this article.

The largest population groups in Ohio include people of German, Irish, and English descent. About 11 percent of the state's people are African Americans. People of Hispanic and Asian origin each account for less than 2 percent of Ohio's population.

Schools. The first school in Ohio opened in 1773 at Schoenbrunn, near present-day New Philadelphia. It was set up for Indian children by David Zeisberger, a Moravian missionary. Ohio's public-school system began in

Ohio State University at Columbus has one of the largest student populations of any campus in the United States. University Hall, shown here, is located in the center of the campus.

Population density

About 85 percent of Ohio's people live in the state's metropolitan areas. About half of the state's people live in the metropolitan areas of Cincinnati, Cleveland, and Columbus.

WORLD BOOK map: based on U.S. Census Bureau data.

The Toledo Festival of the Arts features arts and crafts, food, and entertainment. This popular event takes place annually over the Labor Day weekend.
1825, and public high schools were authorized in 1853. During the 1800's, several Ohio educators wrote school textbooks that were used in public schools throughout the United States. The most famous of these educators was William H. McGuffey (see McGuffey, William H.).

Many colleges were founded in Ohio in the 1800's. Oberlin College, established in 1833, became the first college in the United States for both men and women.

The State Board of Education supervises all elementary schools and high schools in Ohio. This board consists of 11 members elected to four-year terms and eight members appointed by the governor. These members appoint the state superintendent of public instruction. Ohio law requires children from age 6 through 17 to attend school. For the number of students and teachers in Ohio, see Education (table).

**Libraries.** A subscription library opened at Belpre in 1795. In 1804, the famous Coonskin Library was founded at Ames (now Amesville). Pioneers bought its first books with animal skins. Many of these books have been preserved by the Ohio Historical Society in Columbus. The State Library of Ohio in Columbus was established in 1817 as a reference library for state officials. The Cleveland Public Library is one of the biggest in the United States. Other large libraries in Ohio include the Public Library of Cincinnati and Hamilton County, the University of Cincinnati Library, and the Ohio State University Library in Columbus. Columbus is Ohio's largest library center. The library of the Rutherford B. Hayes Presidential Center in Fremont honors the 19th U.S. president. It opened in 1916 and was the nation's first presidential library. The Cincinnati Historical Society highlights early Ohio and metropolitan Cincinnati.

The Cleveland Museum of Art exhibits one of the finest collections of art in the world. The visitors shown in this photograph are viewing paintings in the Renaissance Gallery.

**Museums.** The Cleveland Museum of Art, the Cincinnati Art Museum, and the Toledo Museum of Art all own renowned collections of art from many different periods and cultures. The Taft Museum in Cincinnati displays paintings and Chinese porcelain. The U.S. Air Force Museum at Wright-Patterson Air Force Base near Dayton exhibits old and modern airplanes. The Rock and Roll Hall of Fame and Museum in Cleveland has displays and interactive exhibits about the history of rock music.

"Campuses at Athens, Lancaster, St. Clairsville, and Zanesville."
Visitor’s guide

Ohio has hundreds of historical, recreational, and scenic attractions. Historical points of interest include huge Indian burial mounds and forts that date back to prehistoric times.

The 2,500 lakes and 44,000 miles (70,800 kilometers) of rivers and streams in Ohio provide many opportunities for boating, fishing, and swimming. Lake Erie is a major tourist and recreational attraction. Hunters shoot deer, ducks, and rabbits in the state’s woods and on the rolling plains. Many vacationers enjoy hiking in the hilly eastern section of Ohio, which has some of the state’s most beautiful scenery.

Two historical plays performed outdoors rank among Ohio’s most popular annual events. Tecumseh, a drama about the famous Shawnee Indian, is held near Chillicothe. Trumpet in the Land, which concerns Ohio’s first permanent white settlement, is performed near New Philadelphia. Both plays run from June to September.

Places to visit

Following are brief descriptions of some of Ohio’s most interesting places to visit:

Adena State Memorial, in Chillicothe, is a restored stone house built in 1807 by Thomas Worthington, who later became governor of Ohio. It is furnished with rare American antiques of the 1700s and early 1800s.

Campus Martius Museum, in Marietta, stands on the site of the fortified stockade built by the first permanent white settlers in Ohio. The museum includes the home of Rufus Putnam, the founder of Marietta. The nearby Ohio River Museum exhibits models, pictures, and relics of riverboats.

Fort Recovery, in the village of Fort Recovery, is a reproduction of part of the fort that General Anthony Wayne built in 1793. General Wayne used the fort during the Indian wars in Ohio.

Indian mounds and other earthworks may be seen throughout the state. Fort Ancient, near Lebanon, is the largest hilltop earth structure in the United States. Its earthen walls, more than 20 feet (6 meters) high and 3 miles (5 kilometers) long, enclose over 100 acres (40 hectares). Fort Hill, near Bainbridge, is a 1,200-acre (486-hectare) area with a great walled enclosure on a high hill. Great Serpent Mound, near Hillsboro, is one of the best-known prehistoric structures in the world. The mound, shaped like a snake, has seven deep curves. It rises about 4 feet (.12 meters) and extends over 0.5 mile (0.8 kilometer). Newark Earthworks, at Newark, includes an octagonal earthen ridge that encloses about 50 acres (20 hectares), and circular earthen walls that enclose about 20 acres (8 hectares).

Kelleys Island, in Lake Erie near Sandusky, is a summer resort famous for its glacial markings and Inscription Rock. The markings—grooves cut into surface limestone by glaciers—are among the best examples of glacial action in the world. Inscription Rock is a large boulder with traces of prehistoric Indian carvings.

Pro Football Hall of Fame, in Canton, annually honors outstanding professional football players. It includes a museum of equipment that was worn by famous players and used in famous games.

Roscoe Village, in Coshocton, is a restored community that illustrates life on the Ohio and Erie Canal in the 1830s. It features homes, businesses, and a horse-drawn canal boat.

Rutherford B. Hayes Library and Museum, in Fremont, are at the former President’s Spiegel Grove estate. The library has papers of Hayes and books on American life during the 1800s. The museum features exhibits on the life and times of Hayes and his family.

Schoenbrunn Village, near New Philadelphia, consists of reconstructed portions of the Moravian mission settlement founded there in 1772 for Indians. The site includes a replica of the first schoolhouse in what is now Ohio.

Wright-Patterson Air Force Base, near Dayton, is the nation’s largest U.S. Air Force research field. The base includes the field on which the Wright brothers conducted their airplane experiments, and houses the world’s largest military aviation museum.

Zoar Village, near New Philadelphia, was founded in 1817 by a group of Germans seeking freedom from religious persecution. The home of their leader, Joseph Bimeler, and the old Zoar Garden can be seen.

National forests and parklands. Wayne National Forest, the only national forest in Ohio, lies in the southeastern part of the state. Perry’s Victory and International Peace Memorial stands at Put-in-Bay on South Bass Island in Lake Erie. It honors the American victory in the Battle of Lake Erie during the War of 1812, and a hundred years of peace between the United States and Canada. The granite shaft, 352 feet (107 meters) high, is one of the nation’s tallest memorials. It has an observation deck at the top. Hopewell Culture National Historical Park, near Chillicothe, has many prehistoric Indian mounds. The Cuyahoga Valley National Recreation Area stretches along the Cuyahoga River between Akron and Cleveland. The William Howard Taft National Historic Site, in Cincinnati, includes the birthplace of the 27th President.

State parks and forests. Ohio has 72 state parks and 19 state forests. For information on the state parks of Ohio write to Chief, Division of Parks and Recreation, Fountain Square, Columbus, OH 43224.
Annual events

January-March
Ohio Winter Ski Carnival in Mansfield (February); Buzzard Day in Hinckley (March); Maple Syrup Festival near Oxford (March); American-Canadian Sport Show in Cleveland (March).

April-June
Geauga County Maple Festival in Chardon (April); Appalachian Festival in Cincinnati (May); Walleye Festival in Port Clinton (May); Festival of the Fish in Vermilion (June); Cherry Festival in Bellevue (June); Ports and Maritime Festival in Cleveland (June); Memorial Golf Tournament in Dublin (June).

July-September
Budweiser Cleveland Grand Prix in Cleveland (July); Dayton Air Show in Vandalia (July); Jamboree in the Hills in Morris-town (July); Pro Football Hall of Fame Festival in Canton (July); Ohio State Fair in Columbus (August); Salt Fork Arts & Crafts Festival in Cambridge (August); Ohio River Sternwheel Festival in Marietta (September); Riverfest in Cincinnati (September); Grape Jamboree in Geneva (September).

October-December
Bob Evans Farm Festival in Rio Grande (October); Paul Bunyan Show in Nelsonville (October); Apple Butter Stirrin' in Coshocton (October); Pumpkin Show in Circleville (October); Winterfest at Kings Island near Cincinnati (December); Christmas at Ohio Village in Columbus (December); Christmas Candlelightings in Coshocton (December).
Land regions. Several glaciers moved down from the north thousands of years ago, during the Ice Age. They covered all of what is now Ohio except the southeastern part. These separate glacial movements helped create the state's four main land regions. These four regions are (1) the Great Lakes Plains, (2) the Till Plains, (3) the Appalachian Plateau, and (4) the Bluegrass Region.

The Great Lakes Plains of northern Ohio form part of the fertile lowland that lies along much of the Great Lakes. In Ohio, these plains make up a narrow strip of land that borders Lake Erie. The region is 5 to 10 miles (8 to 16 kilometers) wide in the east, and broadens to more than 50 miles (80 kilometers) in the Maumee Valley to the west. A few low, sandy ridges along the Lake Erie shore break the flatness of the plains. A wide variety of crops, especially fruits and vegetables, grows in the region's fertile soil. The region is one of the busiest manufacturing, shipping, trading, and recreational areas in the United States. It includes many lake ports and large industrial cities. The most heavily populated part of Ohio, the Cleveland metropolitan area, is in the Great Lakes Plains region.

The Till Plains are the easternmost part of the rich midwestern Corn Belt, which stretches westward from Ohio. This region ranks among the most fertile farming areas in the country.

Some hills dot the gently rolling plains, which lie in most of western Ohio. One of them, Campbell Hill in Logan County, rises 1,550 feet (472 meters) and is the highest point in Ohio. From there, the land gradually slopes downward to the southwestern corner of the state in Hamilton County. This area, 433 feet (132 meters) above sea level, is Ohio's lowest point. Farmers of the Till Plains produce grain, soybeans, and livestock. The area has many industrial cities where a wide variety of products is manufactured. It also includes Columbus, the State Capital.

The Appalachian Plateau includes almost all the eastern half of Ohio. This highland extends eastward into Pennsylvania and West Virginia. The southern two-thirds of the region was not covered by glaciers. As a result, this section is the most rugged part of the state, with steep hills and valleys. Most of the soil is thin and not fertile. The northern third of the Appalachian Plateau has rolling hills and valleys, and has less fertile soil than that of the Till Plains.

The rugged Appalachian Plateau has some of Ohio's most beautiful scenery, including the state's largest forests and some waterfalls. It also has Ohio's richest mineral deposits—clay, coal, natural gas, oil, and salt. A few of its cities are important manufacturing centers.

The Bluegrass Region, Ohio's smallest land region, is an extension of the Bluegrass Region of Kentucky. This triangular area in southern Ohio has both hilly and gently rolling land. The hills of the Bluegrass Region have thin, less fertile soil.

Shoreline of Ohio stretches for 312 miles (502 kilometers) along Lake Erie, from Conneaut in the east to Toledo in the west. It includes 53 miles (85 kilometers) along Sandusky Bay, and 66 miles (106 kilometers) along offshore islands. The eastern half of the shoreline consists of clay bluffs about 10 to 18 feet (3 to 5 meters) high. The western half has beaches of clay or sand. Many harbors indent the shoreline. Two of the busy lake ports lie on large bays—Toledo on Maumee Bay, and Sandusky on Sandusky Bay. North and northwest of Sandusky in Lake Erie are some small islands. The largest ones, Kelleys and North, Middle, and South Bass islands, are used chiefly as recreation areas.

Rivers and lakes. Ohio has more than 44,000 miles (70,800 kilometers) of rivers and streams. They flow either south into the Ohio River or north into Lake Erie. A series of low hills separates the two groups of rivers. This divide lies approximately along the southern boundary of the Great Lakes Plains and extends into Indiana. Except for the Maumee River, all the longer, wider rivers flow into the Ohio River. They drain about 70 percent of the state.

The Ohio River, one of the chief rivers of North America, flows more than 450 miles (724 kilometers) along Ohio's southern and southeastern borders. The northern bank of the river forms the state boundary. Many bluffs from 200 to 500 feet (61 to 150 meters) high rise along the river, which winds through a valley less than 2 miles (3 kilometers) wide.

The Ohio River's longest tributary in Ohio is the Scioto River, which is 237 miles (381 kilometers) long. Other rivers flowing into the Ohio include the Hocking.
Little Miami, Great Miami, and Muskingum. The largest rivers that flow into Lake Erie are the Cuyahoga, Grand, Huron, Maumee, Portage, Sandusky, and Vermilion. Some underground streams in Ohio have formed caverns, such as Seven Caves near Bainbridge and Ohio Caverns near West Liberty. Many swift streams in northeastern Ohio have rapids and waterfalls.

Ohio's lake waters include 3,457 square miles (8,954 square kilometers) of Lake Erie. The International Line between the United States and Canada runs through Lake Erie about 20 miles (32 kilometers) north of the Ohio shore. The state has more than 2,500 lakes larger than 2 acres (0.8 hectare). Over 20 of them are natural lakes with an area of 40 acres (16 hectares) or more. These lakes were formed by the ancient glaciers. Ohio also has more than 180 artificially created lakes that cover at least 40 acres (16 hectares) each.

Several lakes were created in Ohio during the 1830s and 1840s to feed water into two canals. These canals were the Ohio and Erie Canal, between Cleveland and Portsmouth, and the Miami and Erie Canal, between Toledo and Cincinnati. They were Ohio's chief means of Average January temperatures

Ohio has cold winters. Only the far southern section has temperatures that average above the freezing level.

Average July temperatures

The state has warm, humid summers. The south is the warmest and the areas along Lake Erie have the mildest summers.

Average yearly precipitation

The southern part of Ohio is the wettest, and the northwest is the driest. The northeast receives the heaviest snowfall.
transportation until the coming of the railroads in the 1840's. The largest lake in Ohio is 12,700-acre (5,140-hectare) Grand Lake near Erie Canal. It was created during the 1840's by damming two nearby creeks to provide water for the Miami and Erie Canal. Other large artificially created lakes include Berlin, Indian, Mosquito Creek, and Senecaville lakes.

**Plant and animal life.** Forests cover about a fourth of Ohio. Most of the state's trees are hardwoods. They include beeches, black walnuts, hickories, maples, sycamores, red and white oaks, tulip trees, white ashes, and white elms. Among the common shrubs found in Ohio are azalea, dogwood, hawthorn, sumac, and viburnum.

**Economy**

Located in the heart of the Rust Belt, the industrial region of the northeastern United States, Ohio has long been known as an important manufacturing center. Manufacturing is the single most important economic activity in Ohio. Its manufacturing industry is characterized by the wide variety of goods produced. The manufacture of aircraft parts, machine tools, motor vehicles, soap, steel, and plastics are all billion-dollar businesses in Ohio.

Service industries, taken together, account for the largest portion of Ohio's gross state product—the total value of goods and services produced annually. Community, business, and personal services are the state's leading service industry. Coal is the leading mined product. Soybeans and corn rank as Ohio's most valuable agricultural products.

**Natural resources.** Fertile soils and valuable minerals are Ohio's most important natural resources.

**Soil.** Fertile soils deposited by ancient glaciers are found in all parts of Ohio except the southeast. Many layers of these soils are several feet deep. Materials in the various kinds of soils include limestone, sandstone, and shale. The soil is less fertile in the southeastern part of the state, which was not covered by glaciers during the ice age.

**Minerals.** Coal is Ohio's most important mined product. Deposits in eastern and southeastern Ohio have an estimated 24 billion tons (22 billion metric tons) of coal.

The state's wildflowers include anemones, blazing stars, blue sages, Indian pipes, lilles, saxifrages, toothworts, and wild indigos.

Ohio has few large wild animals. Only white-tailed deer are plentiful. Smaller wild animals include minks, muskrats, opposums, rabbits, raccoons, red foxes, squirrels, skunks, and woodchucks. Among Ohio's songbirds are blackbirds, brown thrashers, cardinals, chickadees, and wrens. Bald eagles and various shore birds live along Lake Erie. Game birds include ducks, geese, pheasants, quail, and ruffed grouse. Fish living in the state's waters include bass, bluegills, catfish, muskelunge, perch, pike, and walleye.

**Climate.** Ohio has cold winters and warm, humid summers, with an average annual temperature of 52 °F (11 °C). The average January temperature is 28 °F (−2 °C), and the July temperature averages 73 °F (23 °C). Ohio's lowest recorded temperature, −39 °F (−39 °C), occurred at Milligan, near New Lexington, on Feb. 10, 1899. The highest recorded temperature was 113 °F (45 °C) near Gallipolis on July 21, 1934.

Ohio's annual precipitation (rain, melted snow, and other moisture) averages 38 inches (97 centimeters). The wettest area is in the southwest, where Wilmington's yearly precipitation is 44 inches (112 centimeters). The driest part of Ohio lies along Lake Erie between Sandusky and Toledo. It gets 32 inches (81 centimeters) of precipitation a year. Snowfall in Ohio averages 29 inches (74 centimeters) a year. It increases from west to east, and from south to north. Northeastern Ohio receives about 100 inches (254 centimeters) of snow annually and has several ski areas.

Oil and natural gas are found in several parts of Ohio. The state has about 100 million barrels of crude oil reserves. Ohio also contains huge reserves of rock salt and saltwater. The state could supply the United States with all the salt it needs for thousands of years. Most of the salt lies in deep rock-salt beds in northeastern Ohio. Other mined products in the state include large deposits of clay, gypsum, limestone and dolomite, sand and gravel, and sandstone.

**Service industries,** as a group, account for the largest portion of Ohio's gross state product and employ more people than any other type of industry. Most of the service industries are concentrated in the state's metropolitan areas.

Community, business, and personal services lead the service industries in terms of the gross state product. This group also employs more of Ohio's people than any other industry. Community, business, and personal services consist of a variety of businesses, including private health care, engineering firms, hotels, law firms, private research organizations, and repair shops. Cleveland is a leading center of health care in the United States. Columbus is the home of Battelle Memorial Institute, one of the world's largest private research organizations.

Wholesale and retail trade ranks second among service industries in contributions to the gross state product. The wholesale trade of coal, groceries, motor vehicles
and motor vehicle parts, and steel is important in Ohio. The ports of Toledo and Cincinnati handle much wholesale trade. Columbus is a leading distribution center for store merchandise. Retail businesses include department stores, food stores, and restaurants. The Cincinnati area is the home of several major U.S. retail companies, including Federated Department Stores and Kroger. Wendy's, a leading restaurant chain, is headquartered in Dublin. The Limited, a major retail clothing chain, is headquartered in Columbus.

Finance, insurance, and real estate ranks next among the service industries in terms of contribution to Ohio's gross state product. This industry group is most important in Cleveland and Columbus. Most of Ohio's largest banks are based in these cities, including Keycorp and National City of Cleveland. Cincinnati is also the home of several large financial companies. Several large insurance companies, including Nationwide and Progressive, have headquarters in Ohio. Real estate businesses have grown rapidly in the suburban parts of the large metropolitan areas.

Next among Ohio's service industries are government services, which include public schools and hospitals, and military bases. The public school system employs many people. Wright-Patterson Air Force Base lies near Dayton. State government offices are based in Columbus, which is also the home of Ohio State University.

Transportation, communication, and utilities rank fifth among Ohio's service industries in terms of contribution to the gross state product. Shipping is an important part of the transportation sector. Several large shipping companies lie along Lake Erie and the Ohio River. Roadway Express, a major trucking company, is headquartered in Akron. Telephone companies are the largest part of the communications sector. Ohio's largest utility companies are American Electric Power of Columbus and FirstEnergy of Akron. More information about transportation and communication appears later in this section.

Manufacturing contributes more to the gross state product than any other industry. Products made in the state have a value added by manufacture of about $120 billion a year. This figure represents the increase in value of raw materials after these materials become finished products. Ohio ranks high among the states in total value added by manufacture.

Transportation equipment is Ohio's leading manufactured product by far. The most important types of transportation equipment made in Ohio are motor vehicles, motor vehicle parts, and aircraft parts. Automobiles are assembled in East Liberty, Lordstown, and Marysville. The state's largest truck factories are in Avon Lake, Chillicothe, Lorain, Moraine, Springfield, and Toledo. Motor vehicle parts come mainly from Cleveland, Dayton, and Toledo. Large factories that produce aircraft parts are in Akron, Cleveland, and Everdeen.

Fabricated metal products rank second among Ohio's manufactured products in terms of value added by manufacture. This category includes structural metal, metal stampings for automobiles, tools and hardware, and valves and pipe fittings. The Cleveland area leads the state in fabricated metal products.

Chemicals rank third in terms of value added by manufacture. Ohio's leading chemical products include soaps and cleansers, industrial chemicals, and paints and varnishes. The Procter & Gamble Company, a major manufacturer of soaps and cosmetics and many other products, is based in Cincinnati. Its soap factory in Cincinnati is the largest in the United States.

Primary metals rank fourth among Ohio's manufactured products. Indiana is the only state that produces more raw steel than Ohio. The largest centers of steel production are in the Canton, Cleveland, Lorain, Middle town, and Warren areas. Cincinnati and Cleveland have aluminum foundries.

Machinery is Ohio's fifth most valuable type of manufactured product in terms of value added by manufacture. The state's major machinery products are bearings, heating and cooling equipment, and machine tools and machine tool parts. Cincinnati, Cleveland, and Dayton are the chief centers of machine tool production in the state. Plants in Dayton make air-conditioning and ventilation equipment. Large factories in Canton manufacture ball and roller bearings.

Food products are Ohio's sixth-ranking manufactured product. The Cincinnati and Columbus areas are the state's main food processing centers. Cincinnati has meat packing plants. Factories in Columbus make beer and bakery products. Cooking oils are made in St. Bernard. Mariemont has a plant that makes cookies and crackers. Solon makes frozen dinners. Dairy products, which include pasteurized milk and cheese, are also important. The world's largest soup factory operates at Napoleon. A factory at Wellston is the world's leading producer of frozen pizzas.

Ohio is also an important manufacturer of rubber and plastic products, electrical equipment, computer and electronic equipment, clay and glass products, printed materials, and paper products. Factories in Akron, Dayton, and Findlay make such rubber products as hoses and tires. Goodyear Tire & Rubber, a major manufacturer of tires and other rubber products, has its headquarters in Akron. Many cities in Ohio produce plastic products. Types of electrical equipment manufactured in Ohio include appliances, electric motors, and lighting
equipment. Electronic equipment includes communication systems and scientific instruments. Clay products include bricks and tile, roofing, and tableware. Much pottery is manufactured along the Ohio River, especially in East Liverpool. Toledo and various other cities in Ohio are centers of the glassmaking industry. Plentiful deposits of sand and natural gas, which are used in glassmaking, helped establish the glassmaking industry in the state. Printed materials include newspapers and business forms. Many Ohio cities make paper products. Mead, a major manufacturer of paper and other wood products, is headquartered in Dayton.

Agriculture. Ohio has about 80,000 farms. Farms and ranches cover about half the state's land area.

Field crops provide most of Ohio's agricultural income. Soybeans are the state's leading farm product. Corn ranks second. Ohio ranks among the leading producers of both corn and soybeans. Farmers grow these two crops in nearly all parts of the state, especially in the Till Plains region. Other field crops raised in the state include hay, oats, popcorn, and wheat. Most of the grain production is used for livestock feed.

Milk is the leading livestock product in Ohio. Most of the milk produced in Ohio is sold in nearby cities. The state's leading dairy-farming areas include Wayne, Holmes, Columbiana, and Tuscarawas counties in the northeast, and Mercer County in the west.

Many farmers in Ohio raise beef cattle. Ohio also ranks as a major hog-producing state. Farmers in the Miami River Valley developed the famous Poland China hog during the 1800s. A monument to the Poland China breed stands near Monroe. Farmers also raise sheep for both mutton and wool, chiefly in the central part of the state. Ohio produces more wool than any other state east of the Mississippi River.

Ohio is one of the leading states in egg production. Most of the egg-producing poultry farms are located in the west-central and east-central parts of the state. Ohio poultry farmers also raise turkeys and broilers (chickens from 5 to 12 weeks old).

Ohio has been an important fruit-producing state since pioneer days, when Johnny Appleseed roamed the countryside planting apple seeds (see Appleseed, Johnny). In addition to apples, Ohio farmers produce grapes and strawberries. Grapes are raised on the plains along Lake Erie and on the offshore islands. The warm lake winds protect the grapes from frosts in late spring and early autumn. Some of the grapes are made into wine.

Large crops of cucumbers, sweet corn, and tomatoes are grown in Ohio. The rich soils of the Great Lakes Plains and the warmer lowlands located along the Ohio River are especially good for growing vegetables. During the cold season, vegetables are grown in heated glass shelters called hothouses. Other vegetables grown in Ohio include cabbage, celery, lettuce, peppers, and snap beans. The plains and lowlands in the state also have tree nurseries and flower greenhouses.

Mining. Coal is the greatest source of Ohio's mining income. The state's great fields of bituminous (soft) coal lie mainly in the east and southeast. Belmont, Meigs, Monroe, Morgan, and Vinton counties produce the most coal. The fields there form part of the great Appalachian coal fields that include parts of Pennsylvania and West Virginia.

Natural gas is the second most valuable mined product in Ohio. The southeastern part of the state is the leading area for natural gas production. Gas is pumped from the wells to businesses and homes, where it is used mainly for heating.

Economy of Ohio

This map shows the economic uses of land in Ohio and where the state's leading farm and mineral products are produced. Major manufacturing centers are shown in red.

- Cropland
- Grazing land mixed with cropland and woodland
- Mostly woodland
- Urban area
- Manufacturing center
- Mineral deposit

WORLD BOOK map
Ohio leads all states in the production of building sandstone, providing about a third of the country's supply. Sandstone is taken chiefly from quarries in eastern and northern Ohio. The best-known variety of sandstone, Berea or grit, comes from Lorain County. Ohio's best clay comes from the eastern part of the state, in or near the coal fields. These clays are used in such products as bricks and tile, cement, pottery, and stoneware.

Ohio provides about a fifth of all the limestone used in the United States to make glass. The state also leads in the production of lime, which is made from limestone. Other uses of limestone include the manufacture of cement, chemicals, fertilizers, and steel. Limestone is quarried chiefly in north-central Ohio.

Ohio's oldest mining industry is the production of salt, and the state is a leading salt producer. The deepest salt mine in the United States is near Fairport Harbor, northeast of Cleveland. The mine is about 2,000 feet (610 meters) deep. Petroleum is mined in several parts of eastern Ohio. Sand and gravel are produced throughout the state. Ohio's other mined products include abrasives, dolomite, and gypsum.

Electric power. Plants that burn coal provide about 85 percent of the electric power generated in Ohio. Air pollution from these plants is a major problem. Nuclear plants produce most of the remaining power.

Transportation. Ohio is a transportation link between the eastern and western United States. Cross-country railways and roads began going westward through the state during the 1800's.

The first east-west roads in Ohio were the natural trails that followed the sandy ridges along Lake Erie. Later roads, paved with logs, followed Indian trails. The historic Zane's Trace, built for the federal government by Ebenezer Zane, opened in 1797. It ran from what is now Wheeling, West Virginia, through the present-day Ohio cities of Zanesville, Lancaster, and Chillicothe to Maysville, Kentucky. Maysville was then the northern end of the road to New Orleans. During the early 1800's, the National (Cumberland) Road became an important link between the East and the West (see National Road).

Today, Ohio has about 115,000 miles (185,000 kilometers) of roads, most of which have hard surfaces. Many multilane highways and expressways cross the state. The 241-mile (388-kilometer) Ohio Turnpike runs from the Pennsylvania border across northern Ohio to Indiana. Four major railroad lines provide freight service in the state, and passenger trains serve about 10 cities.

Cleveland Hopkins International Airport is Ohio's busiest airport. Columbus, Dayton, and Toledo also have major airports. The largest airport serving the Cincinnati area lies in nearby Boone County, Kentucky.

The Great Lakes and the St. Lawrence Seaway connect Ohio with the Atlantic Ocean. Ice closes this passage in January and February. The Great Lakes also link Ohio with the north-central states and Canada. Another major waterway, the Ohio River, connects the state with the Mississippi River and the Gulf of Mexico. The entire length of this waterway is navigable all year.

Communication. The first newspaper published north and west of the Ohio River, the Controil of the North-Western Territory, was founded in Cincinnati in 1793. The nation's first antislavery newspaper, the Philanthropist, began publication in Mount Pleasant in 1817. Today, the state has about 80 daily newspapers and 250 weeklies. The largest daily newspapers include the Akron Beacon Journal, The Blade of Toledo, The Cincinnati Enquirer, The Cincinnati Post, The Columbus Dispatch, Dayton Daily News, and Plain Dealer of Cleveland. About 370 periodicals are published in Ohio.

Ohio's oldest radio station, WHK, began broadcasting in Cleveland in 1922. Also in 1922, Ohio State University in Columbus started WOSU, the first educational radio station in North America. The first Ohio TV station, WEWS-TV, opened in Cleveland in 1947. Today, Ohio has about 310 radio stations and about 45 TV stations. Cable television systems and Internet providers serve communities statewide.

Government

Constitution of Ohio, the second in the state's history, was adopted in 1851. Ohioans adopted their first constitution in 1802. An amendment may be proposed by (1) the state legislature, (2) a petition signed by 10 percent of the voters, or (3) a constitutional convention. A convention may be called if it is approved by two-thirds of each house of the legislature and by a majority of the voters. Ohioans also vote every 20 years as to whether they wish to call a constitutional convention. Amendments to the Constitution must be approved by a majority of the people voting on them in an election.

Executive. The governor of Ohio is elected to a four-year term. He or she can serve an unlimited number of terms, but not more than two terms in succession. The governor has the power to appoint the heads of many of the state's administrative departments and agencies and also the trustees of state-supported universities and institutions. The appointments of the governor must be approved by the state Senate.

Voters elect the lieutenant governor, secretary of state, attorney general, treasurer, and auditor. These officials may not serve more than two terms in succession.

Legislature, called the General Assembly, consists of a 33-member Senate and a 99-member House of Representatives. Voters in each of Ohio's 33 senatorial districts elect one senator. Senators serve four-year terms and may not serve more than two terms in succession. Voters in each of the state's 99 representative districts elect one representative. Representatives serve two-year terms and may not serve more than four terms in succession. Regular legislative sessions begin on the first Monday of January in odd-numbered years and have no time limit.

A 1903 amendment to the state Constitution required that each county have at least one representative, regardless of its population. In 1964, the Supreme Court of the United States ruled this amendment unconstitutional. In 1965, Ohio's governor, the state auditor, and the secretary of state drew up a reapportionment (redistricting) plan for the Senate and House of Representatives. They set up single-member legislative districts that were as equal in population as possible. A special three-judge
federal district court approved the plan for use until a permanent plan could be drawn. The Supreme Court of the United States approved the federal district court’s decision. In 1967, the Constitution was amended to provide for a permanent reapportionment plan.

**Courts.** The highest appeals court in Ohio is the Supreme Court. It has a chief justice and six other justices—all elected to six-year terms. Ohio also has 12 courts of appeals. The court of Cuyahoga County has 12 judges. The other districts in Ohio have from 3 to 8 judges each. The highest trial courts in Ohio are the courts of common pleas. Each of the state’s 88 counties has one such court. These courts have varying numbers of judges, all of whom are elected to six-year terms. Other courts in Ohio include county, juvenile, municipal, mayor, and probate courts.

**Local government.** Ohio has 88 counties. All of the counties except Summit are governed by an elected three-member board of commissioners. Summit County is governed by an elected county executive and a seven-member council. By law, counties may have home rule—that is, a county may adopt its own charter. But only Summit County has done so.

Ohio law defines cities as incorporated communities with at least 5,000 people. Villages have populations of less than 5,000. Officially, Ohio has no towns. Ohio law allows cities and villages to adopt home rule, and about a fourth of them have done so. The home-rule cities and villages have mayor-council, council-manager, or commission governments. In 1913, Dayton became the nation’s first large city to adopt council-manager government. About three-fourths of Ohio’s cities and villages have a mayor-council government.

**Revenue.** Taxes account for more than half of the state government’s general revenue (income). Most of the rest comes from federal grants and other U.S. government programs. A general sales tax and a personal income tax are the leading sources of tax revenue. Other state taxes include those on motor fuels, corporate income, public utilities, and motor vehicle licenses. Other revenue comes from charges for government services and from a state lottery.

**Politics.** Both the Democratic and Republican parties have much strength in Ohio. The Democratic Party is strongest in Cleveland and other metropolitan areas in northeastern Ohio. The Republican Party is dominant in most rural areas and is also strong in the Cincinnati and Columbus metropolitan areas. Since the end of World War II in 1945, Democratic and Republican candidates have won elections for governor about an equal number of times.

Ohio is often called a barometer state in national politics. That is, the political views of Ohioans frequently indicate those of most Americans. For example, the winning presidential candidates have won Ohio’s electoral votes in a great majority of presidential elections since 1804. For Ohio’s electoral votes and its voting record in presidential elections, see Electoral College (table).
Indian days. Thousands of years ago, prehistoric Indians lived in what is now Ohio. These Indians were the ancestors of peoples called Mound Builders, some of whom had high forms of civilization. The Mound Builders left more than 6,000 burial mounds, forts, and other earthworks throughout the Ohio region. The Indians included the Adena and Hopewell peoples, who lived there from about 600 B.C. to about A.D. 500. See Mound Builders.

When the early white settlers arrived, several Indian tribes lived in the Ohio region. These tribes included the Delaware, Miami, Shawnee, and Wyandot, or Huron.

Exploration and settlement. The French explorer René-Robert Cavelier, Sieur de La Salle, was probably the first white person to reach present-day Ohio. He is believed to have visited the region about 1670. The French based their claim to the entire Northwest on La Salle’s explorations. But the British claimed all the territory extending inland from their Atlantic colonies. In 1750, the Ohio Company of Virginia sent Christopher Gist to explore the upper Ohio River Valley. This company, organized in 1747, was made up of English people and Virginians who planned to colonize the Ohio region. See Gist, Christopher; La Salle, Sieur de; Ohio Company (The first Ohio Company).

The dispute between Britain and France over territory in North America, including the Ohio region, led to the French and Indian War (1754-1763). In the peace treaty of 1763, France gave Britain most of its lands east of the Mississippi River. Pontiac, an Indian chief believed to have been born in Ohio, started an Indian rebellion against the British in 1763 after the peace treaty was signed. See French and Indian wars; Pontiac.

Fighting during the Revolutionary War in America (1775-1783) forced a Moravian mission settlement named Schoenbrunn, near present-day New Philadelphia, to close down. The settlement, founded in 1772 by David Zeisberger, was abandoned in 1776. In 1780, George Rogers Clark defeated Shawnee Indian allies of the British in the Battle of Piqua, near present-day Springfield. Clark’s campaigns in the Northwest helped win the region for the United States during the Revolutionary War.

The region, including Ohio, became the Northwest Territory in 1787. The Northwest Ordinance of 1787 provided for the eventual statehood of Ohio and other divisions of the territory. That year, the Ohio Company of Associates bought land northwest of the Ohio River in the Muskingum River Valley. Members of this company came from New England. On April 7, 1788, the company founded Marietta, the first permanent white settlement in Ohio. Rufus Putnam, a Revolutionary War general, was superintendent of the colony. Marietta became the first capital of the Northwest Territory in July 1788. Soon other communities developed along the Ohio River. Many settlers were Revolutionary War veterans who received land in payment for their military service. See Northwest Territory; Ohio Company (The second Ohio Company); Putnam, Rufus.

For several years, Indian uprisings disturbed the settlers. Several raids were led by Little Turtle, a Miami chief. In 1794, General Anthony Wayne defeated the Indians near present-day Toledo in the Battle of Fallen Timbers. The next year, in the Treaty of Greenville, the Indians ceded the United States about two-thirds of what is now Ohio. The Indians accepted the treaty largely through the influence of Tarhe, or Crane, a Wyandot chief. With peace restored, more and more settlers poured into the region. Many settlements were founded in the valleys of rivers flowing into the Ohio. Some pioneers also settled in northeastern Ohio in the area called the Western Reserve (see Western Reserve).

In 1800, Congress passed the Division Act. This legislation created the Indiana Territory out of the western part of the Northwest Territory. Chillicothe became the capital of the eastern part, which continued to be called the Northwest Territory.

Statehood. Preparation for Ohio statehood began in November, 1802, when a convention in Chillicothe drew up the state’s first constitution. Ohio became the 17th state on March 1, 1803, when the first state legislature met. Edward Tiffin, a Democratic-Republican, was the

Commodore Oliver H. Perry defeated the British in the Battle of Lake Erie during the War of 1812. While the battle raged, he rowed from a disabled ship, the Lawrence, to take command on the undamaged Niagara.
Ohio

Historic Ohio

The Underground Railroad in Ohio helped slaves reach Canada. The slaves had escaped from the South across the Ohio River. Many abolitionists lived in Ohio.

B. F. Goodrich began making rubber products in Akron in 1870. Akron became a major tire manufacturer after pneumatic tires (tires filled with compressed air) were first used on automobiles in 1895.

The Wright Brothers built the first wind tunnel in North America in Dayton in 1901. They used it to conduct experiments that led to the first successful airplane flight.

World Book illustrations by Kevin Chadwick

Important dates in Ohio

1670 The French explorer René-Robert Cavelier, Sieur de La Salle, probably was the first white man to reach the Ohio region.
1747 The Ohio Company of Virginia was organized to colonize the Ohio River Valley.
1763 France surrendered its claim to the Ohio region to Britain.
1787 The Northwest Territory was established.
1857 The first permanent white settlement in Ohio was established in Marietta.
1795 Indian wars in the Ohio region ended with the Treaty of Greenville.
1800 The Division Act divided the Northwest Territory into two parts, and Chillicothe became the capital of the new Northwest Territory.
1803 Ohio became the 17th state on March 1.
1813 Commodore Oliver H. Perry's fleet defeated the British in the Battle of Lake Erie.
1832 The Ohio and Erie Canal was completed.
1836 The Ohio-Michigan boundary dispute was settled.
1845 The Miami and Erie Canal was completed.
1870 Benjamin F. Goodrich began the manufacture of rubber goods in Akron.
1914 Ohio passed the Conservancy Act after floods in 1913.
1922 The Miami River Valley flood-control project was finished.
1938 The flood-control project in the Muskingum River Valley was completed.
1955 The Ohio Turnpike was opened to traffic.
1959 Terms of the governor and other high state officials were increased from two years to four.
1967 Ohio voters approved a plan for reapportionment of the state legislature.
1971 Ohio adopted an income tax.
1993 Ohio voters approved the sale of $200 million worth of bonds to finance improvements and expansion in the state's parks and other recreation areas.
Ohio

first governor. Ohio’s population was about 70,000. Chillicothe was the capital from 1803 to 1810, when Zanesville became the capital. Chillicothe again became the capital in 1812, and Columbus in 1816.

The Louisiana Purchase in 1803 gave Ohio settlers a river outlet for their products. They could ship goods down the Mississippi River and through the port of New Orleans. A thriving river trade with New Orleans soon developed. The first steamboat to travel the Ohio River was the New Orleans, a wood-burning side-wheeler. It first went down the river in 1811.

Ohio took an active part in the War of 1812 (1812-1815). Commodore Oliver H. Perry sailed from Put-in-Bay at South Bass Island off the Ohio shore to battle a British fleet on Sept. 10, 1813. Perry won an important naval victory in this Battle of Lake Erie (see Perry, Oliver H.). After the war, thousands of people moved to Ohio from the eastern states. Many came from New England, New York, and Pennsylvania. Immigrants arrived from Britain and Germany.

In 1818, the steamboat Walk-in-the-Water became the first steamboat on Lake Erie. It demonstrated the practical use of the Great Lakes as a waterway to the West. The Erie Canal across New York from Lake Erie opened in 1825. The Ohio and Erie Canal, joining Cleveland and Portsmouth, was completed in 1832. The Miami and Erie Canal, connecting Toledo and Cincinnati, was completed in 1845. These canals served as busy trade routes for more than 25 years. But the coming of the railroads reduced canal traffic. Ohio canals and railroads brought increased prosperity, and many mills and factories were built between 1830 and 1860.

An old border dispute between Ohio and the Territory of Michigan flared up in 1835 and led to the “Toledo War.” Before any actual fighting broke out, President Andrew Jackson sent agents to Toledo to persuade the governors of Ohio and Michigan to accept a truce. In 1836, Congress awarded the disputed area, about 520 square miles (1,350 square kilometers) along Lake Erie, to Ohio. In 1841, William Henry Harrison of North Bend became the ninth President.

The Civil War. During the years before the Civil War (1861-1865), many Ohioans had strong feelings on the question of slavery. Many abolitionists (people opposed to slavery) lived throughout Ohio. They helped slaves who had escaped across the Ohio River on their flight to Canada (see Underground Railroad). Most of Ohio’s Southern sympathizers lived in the southern and north-central parts of the state. In 1862, Clement L. Vallandigham of Dayton became leader of the Peace Democrats Party, which opposed President Abraham Lincoln’s Administration. Vallandigham and other Southern sympathizers were known as Copperheads.

Many famous Civil War commanders were born in Ohio, including Ulysses S. Grant and William T. Sherman. Ohio supplied about 345,000 men to the Union army. This was more than the total quotas requested by 10 presidential calls for soldiers from the state. In 1863, Confederate cavalrymen known as Morgan’s Raiders crossed into Ohio and brought Civil War fighting to its northernmost point. Led by General John Hunt Morgan, they were captured in Columbiana County. Morgan later escaped and returned to the South. See Morgan, John Hunt.

Ohio’s industrial centers grew rapidly after the Civil War. Many workers from other countries settled in the state. The shipping of coal, iron ore, and other bulk goods on Lake Erie increased. Farming continued to be a leading industry, but Ohio also developed into a top manufacturing state. In 1869, the Cincinnati Red Stockings (now Reds) became the first all-professional baseball team. Benjamin F. Goodrich began manufacturing rubber products in Akron in 1870.

Five Ohio-born Presidents, all Republicans, were elected during the 1800s. They were Ulysses S. Grant, Rutherford B. Hayes, James A. Garfield, Benjamin Harrison, and William McKinley. President William Henry Harrison of Ohio was born in Virginia.

The early 1900’s. Ohio’s government was torn by scandal and corruption during the late 1800s. Marcus A. “Mark” Hanna, political boss of Cleveland, and George B. Cox, boss of Cincinnati, both Republicans, controlled state politics. Reform movements began about 1900, and promoted honesty and efficiency in city and state governments. William Howard Taft of Cincinnati became the 27th President of the United States in 1909.

Ohio suffered the worst floods in its history during the spring of 1913. About 350 people lost their lives after rivers overflowed their banks, and damage totaled about $100 million. Most of the destruction occurred in the Miami River Valley, especially at Dayton. In 1914, the state legislature passed the Conservancy Act, the first legislation of its kind in the United States. The chief purpose of the act was to permit the establishment of flood-control districts based on entire river systems. Many flood-control dams and reservoirs were built under the Conservancy Act, including those completed by 1922 in the Miami River Valley. The federal government also built about 20 flood-control dams in Ohio.

After the United States entered World War I in 1917, the state produced vast supplies of war materials. Newton D. Baker of Cleveland served as secretary of war in President Woodrow Wilson’s wartime Cabinet.
 Between world wars. In 1921, Warren G. Harding of Marion became the 29th President. His Democratic opponent was Governor James M. Cox of Dayton. The 1920’s were prosperous years in Ohio, because of continued industrial development. Cincinnati, Cleveland, Dayton, Toledo, and other industrial cities expanded rapidly. Many nearby farms disappeared as the cities grew. The Great Depression that began in 1929 hit these cities hardest in Ohio. Thousands of workers lost their jobs as factories closed. Many farmers lost their land when farm prices dropped sharply.

Government funds and federal agencies such as the Works Progress Administration (WPA), later called Work Projects Administration, helped Ohio recover from the depression during the 1930’s. In 1934, work began on the Muskingum River Valley flood-control project. This project came to national attention in 1937, when most of the dams withstood heavy floodwaters of the Ohio River. It was completed in 1938. Robert A. Taft, who became one of the most powerful U.S. senators, began his first term as Republican senator from Ohio in 1939.

The mid-1900’s. During World War II (1939-1945), Ohio produced aircraft, ships, and weapons. It also contributed steel, tires, and materials to the war effort. The armed services established a number of training centers in the state. During the 1950’s, the Atomic Energy Commission (AEC) built several installations in Ohio. They included the Portsmouth Area Project in Pike County, which produces uranium-235 for use in nuclear reactors. In 1955, the 241-mile (388-kilometer) Ohio Turnpike across northern Ohio opened. Since 1958, the National Aeronautics and Space Administration (NASA) has operated the John H. Glenn Research Center at Lewis Field in Cleveland. Scientists there conduct research on space propulsion systems.

Ohio’s industrial growth moved forward rapidly during the 1960’s. In 1963, the state launched a giant economic development program to attract more industry. Industrial expansion included new aluminum plants and chemical factories in cities in a region along the Ohio River that offered cheap, coal-generated power.

Ohio also entered international trade. Eight Ohio cities on Lake Erie—Ashtabula, Cleveland, Conneaut, Fairport, Huron, Lorain, Sandusky, and Toledo—became ports of the St. Lawrence Seaway, which opened in 1959. By 1970, Ohio ranked fourth among the states in the value of goods exported annually.

Several significant changes occurred in state government. In 1959, Ohio voters increased the terms of the governor and other elected executive officials from two to four years. The Supreme Court of the United States ruled in 1964 that Ohio must reapportion (redistribute) its House of Representatives to provide more equal representation based on population. The state legislature drew up a reapportionment plan for both the House and Senate, which the voters approved in 1967.

Recent developments. The state legislature enacted an income tax in 1971 to help pay for the rising costs of state government. In 1972, voters approved an amendment to the state constitution permitting a state lottery to help fund public schools.

Ohio has now recovered from many of its most troubling problems of the late 1960’s and 1970’s. Between 1966 and the mid-1970’s, several school districts closed their public schools because of a lack of funds. Today, state laws require local school districts to borrow funds from the state government if necessary in order to meet educational expenses. Also, state income taxes were increased during the early 1980’s to help provide funding for public schools and the state-supported university system, and to support other state public services.

Ohio also has had to deal with problems caused by decreasing energy resources. Fuel shortages during the mid-1970’s caused an increase in fuel prices and a decrease in production. During a severe winter in 1977, a shortage of natural gas forced many of the state’s factories, offices, and schools to close temporarily.

In the mid-1980’s, however, abundant natural gas and cheaper petroleum gave a boost to many of Ohio’s important manufacturing industries, including the production of automobiles and chemicals. In 1985, Ohio voters approved a $100 million bond issue to finance research on ways to develop technologies to reduce the high-sulfur content of the state’s coal. The goal was to make the coal meet environmental standards, thus increasing its use. An electric power plant using low-sulfur coal that resulted from the research opened in 1993.

Another serious problem for Ohio has been the pollution of Lake Erie and the state’s rivers. Federal and state antipollution laws and controls have now cleaned up state rivers and Lake Erie for both commercial fishing and recreation. In 1993, Ohio voters approved a $200 million bond issue to finance improvements and expansion in the state’s parks and other recreation areas.

Nevertheless, Ohio continues to have serious problems. Ohio manufacturers—especially the steel industry—face increasing foreign competition. Some of Ohio’s industries have moved to states with warmer climates and cheaper labor. Many Ohio farmers have also had difficulties. Periodic declines in prices for crops and livestock result in lower incomes for farmers. Many smaller farmers have been forced out of business by such slumps.

**Scientists check water quality** from a research vessel in Lake Erie by measuring the quantity and types of microscopic animals called zooplankton in the water. Richard J. Hopkins and Thomas W. Schmidlin
Ohio Company. There were two Ohio Companies in American history. The purpose of each was to colonize the Ohio River Valley.

The first Ohio Company was formed in 1747. It is sometimes called the Ohio Company of Virginia. Its members included London merchants and wealthy Virginians. Among them were George Washington's brothers, Lawrence and Augustine Washington. In 1749, King George II granted the company 200,000 acres (81,000 hectares) west of the Allegheny Mountains in Maryland, Pennsylvania, and Virginia, and on both sides of the Ohio River. The company surveyed the Ohio River Valley. It traded with Indians, built storehouses and roads, and established the first fort at the forks of the Ohio. In 1753, a settlement called Gist's Plantation was founded near Mount Braddock, Pa. The French destroyed the company's strongholds in 1754. The French and Indian War (1754-1763) blocked efforts to settle in the west. The company went out of business in 1792.

The second Ohio Company was the more important. Its official name was the Ohio Company of Associates. It was organized at the Bunch of Grapes Tavern in Boston on March 1, 1786. Eleven delegates, elected by persons interested in the venture, set up the company. They planned to raise $1 million in $1,000 shares, which was payable in almost worthless Continental paper money. Within a year the company distributed 250 shares. The company appointed Manasseh Cutler, Rufus Putnam, and Samuel Parsons to petition the Congress of the Confederation to sell it a tract beyond the Ohio River. Congress approved, and later passed the Northwest Ordinance of 1787 (see Northwest Ordinance).

At first the Ohio Company contracted to buy 1 1/2 million acres (610,000 hectares) at 66 2/3 cents an acre. But because of financial difficulties, these terms were never fully carried out. Congress finally granted title to 750,000 acres (304,000 hectares) in what is now southeastern Ohio. The agreement provided that 214,285 acres (86,718 hectares) could be bought with army warrants, and that 100,000 acres (40,000 hectares) were to be offered free to settlers. One section of each township was reserved for schools, one for religion, and three sections for future disposal by Congress. This last term was designed to keep speculators from monopolizing the territory. Two townships of 46,080 acres (18,648 hectares) were set aside "for the support of an institution of higher learning." This institution was founded at Athens, Ohio, in 1804, and became Ohio University.

The Ohio Company appointed Rufus Putnam as its superintendent. He led an advance party of 47 surveyors, carpenters, boatbuilders, blacksmiths, and laborers to lay out a town where the Muskingum and Ohio rivers joined. The group arrived at the mouth of the Muskingum on April 7, 1788. It founded there the first settlement under the Northwest Ordinance, and named it Marietta in honor of Queen Marie Antoinette of France. The settlers also built a fort called Campus Martius to protect their village. On July 15, Governor Arthur St. Clair established the first capital of the Northwest Territory at Marietta. By April, 1789, three new settlements had been established. The Ohio Company completed its land operations by 1797. It divided its assets among the shareholders, but did not go out of business until about 1832.

Richard J. Hopkins

Ohio River is the second most heavily used commercial river in the United States. Only the Mississippi River has more cargo shipped on it. The Ohio flows 981 miles (1,579 kilometers) through some of the nation's busiest industrial regions and richest farmlands. About 203 million short tons (184 million metric tons) of freight are transported annually on the Ohio. The river serves some of the country's principal coal fields and several major steel-producing districts. It drains an area of about 204,000 square miles (528,400 square kilometers).

The Ohio River begins in Pittsburgh, Pa., where the Allegheny and Monongahela rivers meet. The Ohio flows mainly southwestward and forms the southern borders of Ohio, Indiana, and Illinois, and the northern boundaries of West Virginia and Kentucky. It empties into the Mississippi River at Cairo, Ill. Major branches of the Ohio include the Muskingum, Kanawha, Big Sandy, Scioto, Licking, Great Miami, Kentucky, Green, Wabash, Cumberland, and Tennessee rivers.

Navigation. Almost all the cargo transported on the Ohio River moves on large barges. These barges are pushed by tugboats. Dams and canals provide a minimum water depth of 9 feet (2.7 meters). Locks in the canals raise and lower the water level in the river, en-
ablating ships to travel the entire length of the Ohio River. Coal makes up almost half the total freight shipped on the Ohio. Other major cargoes include agricultural products, chemicals, crushed rock, gravel, petroleum products, sand, and steel products. Among the chief ports along the Ohio are Pittsburgh and Aliquippa, Pa.; Huntington, W. Va.; Cincinnati, Ohio; Louisville, Ky.; and Mount Vernon, Ind.

Animal and plant life. Forests of beech, hickory, oak, poplar, and sycamore trees cover the Ohio River Valley. Animals in these forests include chipmunks, muskrats, raccoons, red foxes, squirrels, white-tailed deer, and woodchucks. Among the fishes in the Ohio are bullheads, bass, catfish, and trout.

Community and industrial wastes and farming chemicals pollute the Ohio. Pollution threatens fish and other wildlife. The Ohio River Valley Water Sanitation Commission regulates the release of river pollutants.

History. In 1669, the French explorer René-Robert Cavelier, Sieur de La Salle, became the first European to see the Ohio River. At that time, Shawnee and other Indians lived along its shores. Throughout the 1700's, traders used the river to explore the entire Ohio River Valley. Settlers traveled on the Ohio to the Northwest Territory after that region was established in 1787.

More than 60 steamboats were active on the Ohio by 1820. After the Civil War ended in 1865, the river became a major corridor for the shipment of raw materials and industrial products. During the early 1900's, the steamboats were gradually replaced by powerful tugboats pushing heavy barges.

Flooding along the Ohio often causes heavy damage. Severe floods in 1937, 1945, and 1963 brought great losses of life and property. Since the 1950's, the federal government has worked with the states bordering the river to build 19 dam-canal structures that control most flooding on the Ohio.

Ohio State University is a state-assisted coeducational institution with campuses in Columbus, Lima, Mansfield, Marion, and Newark, Ohio. The main campus is in Columbus. The university also operates two facilities in Wooster, Ohio—the Agricultural Technical Institute, a two-year college; and the Ohio Agricultural Research and Development Center.

The Columbus campus has colleges of agriculture, the arts, biological sciences, business, dentistry, education, engineering, human ecology, humanities, law, mathematical and physical sciences, medicine, nursing, optometry, pharmacy, social and behavioral sciences, social work, and veterinary medicine. It grants bachelor's, master's, and doctor's degrees. The campuses at Lima, Mansfield, Marion, and Newark offer liberal arts programs leading to associate of arts and bachelor's degrees.

The university operates its own radio and television stations and has an airport near the Columbus campus. The university's Franz Theodore Stone Laboratory, located in Put-in-Bay, Ohio, studies the biology of the Great Lakes.

Ohio State University was founded in 1870 as a land-grant college. Originally called Ohio Agricultural and Mechanical College, the school opened in 1873. It took its present name in 1878. The other campuses were founded between 1957 and 1960.

Critically reviewed by the Ohio State University

Ohio University is a state-assisted coeducational school in Athens, Ohio. The university has nine colleges that grant undergraduate degrees—University College; the honors-tutorial college; and the colleges of arts and sciences, business administration, communication, education, engineering and technology, fine arts, and health and human services. University College offers associate degrees and a bachelor's degree in general studies. The honors-tutorial college has special programs for gifted or highly motivated students.

Ohio University also offers master's and doctor's degrees. It maintains five regional campuses and an academic center in southeastern Ohio. The university also has a lifelong learning division.

Ohio University was founded in 1804. It was the first institution of higher learning in the vast Midwestern region called the Northwest Territory.

Critically reviewed by Ohio University

Ohm is the unit used to measure resistance to the passage of an electric current. All materials resist the flow of electric current. But some materials offer more resistance than others. Materials that offer little resistance are called conductors. Materials that offer great resistance are called insulators. Electrical resistance, measured in ohms ($R$), is equal to the electromotive force producing a current, measured in volts ($E$), divided by the current, measured in amperes ($I$):

$$\text{ohms} = \frac{\text{volts}}{\text{amperes}} \quad \text{or} \quad R = \frac{E}{I}$$

The resistance of a conductor depends on its dimensions and its temperature as well as on the material from which the conductor is made. For example, the resistance of a wire increases as its length increases or as its diameter decreases. Generally, the resistance of a metal increases as its temperature rises.
The international standard for the ohm was adopted in 1893. It was defined as the amount of resistance to a uniform electric current offered by a thread of mercury with a cross-sectional area of one square millimeter and a length of 106.3 centimeters, at a temperature of 0° C. Engineers have worked out the resistance of standard-sized wires for people who work with electric circuits. Resistance in an electric circuit can be measured with an ohmmeter. More accurate measurements can be obtained by using a device called a Wheatstone bridge (see Wheatstone bridge).

**Gregory Benford**

**Ohm, Georg Simon** (1787-1854), a German physicist, in 1827 described the mathematical law of electric currents called Ohm's law (see Ohm's law). The *ohm*, a unit of electrical resistance, was named for him. His discovery was neglected until 1833, when he became a professor of physics at Nuremberg. He was appointed a physics professor at the University of Munich in 1849.

Ohm was born in Erlangen, Germany. He graduated from the University of Erlangen. **Richard G. Olson**

**Ohm's law** is a mathematical formula that expresses the relationship between the electromotive force, electric current, and resistance in a circuit. This relationship was discovered by the German physicist Georg Ohm, and was published in 1827. When applied to a direct-current circuit, Ohm's law states that the electromotive force (*E*), measured in volts, equals the current (*I*) in amperes multiplied by the resistance (*R*) in ohms:

\[ E = IR \]

When the law is used for an alternating-current circuit, resistance is replaced by *impedance* (*Z*), also in ohms. The flow of alternating current produces a *counter-electromotive force*, which resists the current. The strength of such resistance depends on how rapidly the current alternates. Impedance consists of this resistance, called *reactance*, combined with the circuit's regular resistance.

Electricians use Ohm's law to determine the efficiency of circuits. For example, they can calculate how the flow of current will be affected by various arrangements of such circuit components as connecting wires, capacitors, and resistors. **Gregory Benford**

**Oil.** Any greasy substance that does not dissolve in water, but can be dissolved in ether, is classified as an oil. There are many different kinds of oil. Most are lighter than water and are liquid at room temperature. A few, such as lard and butterfat, are solid at room temperature.

Oils may be obtained from animal, mineral, or vegetable sources. This article chiefly discusses animal and vegetable oils. For more information on mineral oils, which include fuel oils, gasoline, and other petroleum products, see Petroleum.

Animal and vegetable oils consist chiefly of carbon, hydrogen, and oxygen, and they belong to a family of materials called lipids. Animal and vegetable oils are classified as fixed or volatile, depending on whether they evaporate under normal conditions.

**Fixed oils**, which do not evaporate under ordinary conditions, are also called *fatty oils* or simply *fats*. They include all animal oils and many vegetable oils. Butterfat, lard, and tallow rank as the chief animal oils. Margarine and salad oil consist mainly of fixed vegetable oils. Other products that are made from fixed oils include candles, linoleum, lubricants, paint, and soap.

Butter makers churn cream to produce butter. People render (heat) fatty animal tissues to obtain other kinds of animal oil. Lard is made from fatty tissues of hogs, and tallow from cattle, goats, or sheep. Oils from such sea animals as fish and whales are called *marine oils*.

Most fixed vegetable oils are extracted from such seeds as corn, cottonseed, and soybeans. Processors obtain olive and palm oils from the fruit pulp surrounding the seed. For information on the processing of fixed vegetable oils, see *Vegetable oil*.

Exposure to air causes fixed oils to thicken. The degree of thickening determines whether the oil is classified as (1) drying, (2) semidrying, or (3) nondrying.

Drying oils absorb oxygen from the air to form a tough film. They are widely used to make paints and varnishes. Important drying oils include linseed, perilla, tung or chinawood, soybean, oiticica, hemp, walnut, poppy seed, and sunflower. Linseed oil comes from flax seeds. It is one of the most important drying oils. It is used in making paints and varnishes. Tung oil is a valuable oil used in waterproof varnishes and quick-drying enamels.

Semidrying oils absorb oxygen from the air to become very thick, but not hard. Cottonseed, corn, and sesame oils are of the semidrying type.

Nondrying oils absorb oxygen from the air with little increase in thickness, but they often become rancid—that is, they develop unpleasant odors and flavors. Olive, peanut, and grape-seed oils, butterfat, and lard are examples of nondrying types.

**Volatile oils**, also called *essential oils*, evaporate quickly, especially when heated. Some of these oils come from plants, and others are artificially created. People use volatile oils chiefly for their flavor or odor. The taste of such food flavorings as lemon, mint, and vanilla extracts results from the volatile oils they include. Volatile oils also flavor chewing gum, tobacco, and toothpaste. Most fine perfumes include fragrant oils obtained from roses and other flowers. Manufacturers use such volatile oils as lemon oil to give a scent to soaps and other cleaning products.

Natural volatile oils are extracted from various parts of plants, including bark, flowers, leaves, roots, seeds, and twigs. Methods of obtaining plant oils used for their scent are described in the *Perfume* article. Food processors follow similar procedures in extracting natural volatile oils for flavoring.

Manufacturers use chemical processes to make artificial volatile oils from coal, petroleum, wood, and other substances. Some artificial oils duplicate natural oils. Others differ from any substance found in nature. Such products as artificial oil of rose and artificial vanilla extract cost much less than similar natural substances.

**Oil gland.** See *Acne*. 
Oil painting. See Painting.
Oil refinery. See Petroleum.
Oil shale is a soft, fine-grained sedimentary rock from which oil and natural gas are obtained. Oil shale consists of light brown layers of silt and darker layers of kerogen, a waxy organic substance that originated from the remains of blue-green algae and other living matter. Vast deposits of oil shale occur in southern Brazil, northeastern China, Estonia, Sweden, and the United States.

Heating oil shale releases crude oil and natural gas from the kerogen. However, it takes huge quantities of rock to obtain a useful amount of oil. As a result, the oil is expensive to produce. The high cost of production has limited the commercial use of the oil. Only Estonia and China now use oil shale. The only commercial-scale oil shale plant in the United States closed in 1991.

Two methods are used to obtain oil from oil shale. In the first process, the mined rock is crushed, transported to a processing plant, and heated to temperatures higher than 900°F (480°C). The heat drives oil vapors from the rock, and they condense into liquid oil. The second process is called the in situ (in place) method. In this method, miners dig a hole into the bottom of a shale deposit. They then dynamite the deposit, which collapses and shatters. A mixture of air and gas is pumped into the deposit and ignited, heating the rock. Oil vapors then separate from the rock and condense, and oil is pumped out.

Oilbirds dwell in caves in tropical regions of northern South America. They have rich brown feathers and large eyes that reflect red in the dark. Oilbirds feed on palm and laurel fruits.

Oilcloth is a heavy, waterproof cloth used to cover tables and walls that must often be washed. It is made of coarse cloth coated with heavy paint. The cloth is stretched on a frame and stiffened with glue. The paint is put on in several coats. Each coat is smoothed with pumice stone after it has dried. Patterns are then printed on, from blocks coated with paint. Oilcloth was first used in China between the 600s and 900s, and in England in the 1500s. The first American oilcloth was made in Philadelphia in 1809. Any smooth vinyl-coated fabric is sometimes called an oilcloth.

Oilbird is a cave-dwelling bird found in the tropics of northern South America. It is related to whippoorwills, goatsuckers, and nightjars but looks more like an owl. Oilbirds have cinnamon-brown feathers with white dots. Adults measure from 12 to 18 inches (30 to 46 centimeters) long. Young oilbirds are unusually plump and contain so much oily fat that they were once slaughtered by people, who used the fat as lamp oil and cooking oil. Oilbirds are also called guacharos.

Oilbirds spend most of their time roosting or flying because their feet are poorly developed for walking. They are active at night and feed largely on the fruits of palm and laurel trees.

Oilbirds build nests of seeds and bird droppings on top of rocks or ledges deep in caves. An oilbird finds its way about caves and at night by means of echolocation. The bird makes sharp clicking sounds that echo off objects to tell the bird where to fly. Oilbirds also make loud, shrill calls at night.

Scientific classification. The oilbird makes up the oilbird family, Steatornithidae. It is Steatornis caripensis.

Oilcloth was invented by an Englishman named William Lobb. He died in 1876, and oilcloth production continued to increase. Oilcloth is still widely used today.
he won first prize in a violin competition in Brussels, Belgium. Abram Lof

Ojibwa Indians. See Chippewa Indians.

Ojos del Salado, oh hohz dehl suh LAH D oh, is the second highest mountain in the Western Hemisphere. Only Aconcagua is higher. Both mountains are part of the Andes range in South America. Ojos del Salado rises 22,572 feet (6,880 meters). It has four distinct peaks on the border between Argentina and Chile. Snow covers Ojos del Salado all year. For location, see Argentina (terrain map). Gregory Knapp

Okapi, oh KAH pee, is a rare animal that lives in dense forests around the Congo River basin in Africa. It was discovered there by European explorers in 1900. The

The okapi is a relative of the giraffe. It has a reddish-brown body, a white face, and white stripes on its legs. Okapis live in rain forests of the Congo River basin in Africa.

Okapi stands about 5 feet (1.5 meters) high at the shoulder. It is related to the giraffe, but its neck is much shorter. The okapi has a dark chestnut body, a white face, and white stripes on its rump and upper legs. The male has a pair of short, hairy horns.

The okapi eats leaves, fruit, and seeds. It travels alone or in pairs. Its chief enemies are leopards and human beings. The okapi has keen hearing and flies when disturbed.

Scientific classification. The okapi belongs to the giraffe family, Giraffidae. It is Okapia johnstoni. Anne Innis Dagg

Okeechobee, Lake. See Lake Okeechobee.

O'Keeffe, Georgia (1887-1986), was an American painter who found most of her inspiration in nature. Her flower paintings, which she created throughout her career, are her best-known works. She is also famous for her paintings of animal skulls and desert landscapes. She painted in a highly personalized style, using strong, vibrant colors. Her forms are sensually smoothed and simplified, often into highly abstract designs.

O'Keeffe was born in Sun Prairie, Wis. She studied at several schools, including the Art Institute of Chicago, the Art Students League, and Columbia University. From 1912 to 1918, O'Keeffe taught in Texas, Virginia, and

South Carolina. In Texas, she first became interested in the American Southwest. The region's desert landscape greatly influenced her work.

The American photographer Alfred Stieglitz first showed O'Keeffe's paintings in 1916 at "291," his experimental gallery in New York City. For years, he displayed O'Keeffe's work at other galleries he operated in New York City. Stieglitz and O'Keeffe were married in 1924. In 1929, O'Keeffe began spending much time in New Mexico. Her husband died in 1946 and she settled near Abiquiu in 1949.

Toward the end of her life, O'Keeffe's eyesight began to fail. She then began to work with ceramics, shaping beautifully rounded, sensuous forms and pottery.

Deborah Leventon

Okefenokee Swamp, OH kuh fuh NOH kee, lies mostly in southeastern Georgia. A small part of it extends into northeastern Florida. Okefenokee Swamp is a marshy, subtropical wilderness. Most of it was bought by the United States government in 1937. The government has set aside about 460 square miles (1,200 square kilometers) of the region as the Okefenokee National Wildlife Refuge.

The name Okefenokee comes from the Indian word Owaquaphenoga, which means trembling earth. It refers to the trembling of the small bushes and water weeds that float on the lakes of Okefenokee.

The swamp covers 700 square miles (1,800 square kilometers). Fine timberlands and freshwater lakes lie next to the marshy stretches. The region is drained by the St. Marys and the Suwannee rivers. Other bodies of water wind through the swamp. There are about 25 islands.
Okefenokee Swamp was once a favorite hunting ground of the Creek and Seminole Indians. Today, as a government preserve, the swamp is the home of many animals, including deer, bears, bobcats, otters, raccoons, opossums, and alligators. The swamp is also the winter refuge of many birds. There are about 50 kinds of fish in its waters. Plants that grow there include white and golden lilies, Spanish moss, and baldcypress trees.

James Q. Wheeler

See also Georgia (map; picture).

Okefenokee Swamp covers about 700 square miles (1,800 square kilometers) of marshy wilderness, chiefly in southeastern Georgia. The United States government has set aside about two-thirds of the region as the Okefenokee National Wildlife Refuge. The preserve provides a recreation area for people, as well as a safe home for many unique varieties of mammals, birds, fish, and plants.

Okinawa

Okinawa, oh kuh NOW wah, or in Japanese, AW khee NAH wah, is the largest and most important island of the Ryukyu Islands. The Ryukus are a chain of islands in the North Pacific Ocean that are part of Japan.

Okinawa covers 465 square miles (1,204 square kilometers). It is the largest island in Japan’s Okinawa prefecture (district), which has a population of 1,318,220. The Okinawa prefecture also includes the southern Ryukyu Islands. Almost all of the prefecture’s population lives on the island of Okinawa. Naha, the capital of Okinawa prefecture and largest city of the Ryukyus, is on Okinawa.

Okinawa was under Japanese control before World War II (1939-1945). The United States occupied Okinawa after the war and administered it and the other Ryukyu islands until 1972. In that year, the United States returned the islands to Japanese control.

Okinawa has had great military importance for the United States because it lies within easy flying distance of China, mainland Japan, the Philippines, Taiwan, and Vietnam. The United States built air bases and other installations on the island and continued to maintain them after returning control of the island to Japan. But in the mid-1990’s, growing dissatisfaction among Okinawans with the U.S. military presence prompted the United States to agree to give up part of the land it administers.

See also Georgia (map; picture).

Okahtsk, oh KAHTSK, Sea of, is a large arm of the North Pacific Ocean on the eastern boundary of Russia. It is separated from the Bering Sea on the east by Russia’s Kamchatka Peninsula. The Kuril Islands on the south separate the Sea of Okhotsk from the Pacific Ocean. For the sea’s location, see Russia (terrain map).

The Sea of Okhotsk is about 1,000 miles (1,600 kilometers) long and about 600 miles (970 kilometers) wide. It covers an area of about 615,000 square miles (1,590,000 square kilometers).

Ice covers the Sea of Okhotsk from November to April, and heavy fogs and storms occur often. But the sea is used as a trade waterway for the Russian ports of Magadan and Okhotsk. The Amur River and smaller streams empty into the Sea of Okhotsk.

Craig ZumBrunnen

Okefenokee Swamp covers about 700 square miles (1,800 square kilometers) of marshy wilderness, chiefly in southeastern Georgia. The United States government has set aside about two-thirds of the region as the Okefenokee National Wildlife Refuge. The preserve provides a recreation area for people, as well as a safe home for many unique varieties of mammals, birds, fish, and plants.
Government. Voters elect a governor to head the prefecture of Okinawa. The prefecture's legislature, the Prefectural Assembly, consists of 48 members. The prefecture's voters also elect five representatives to the Diet (national parliament) in Tokyo.

People. Okinawans look like the Japanese, but Okinawans are shorter and have darker skin. The Okinawan language belongs to the Japanese language family. However, most Okinawans only speak Japanese.

Most Okinawans live in urban areas. Naha and other cities in Okinawa have modern buildings and traffic-choked streets. A few Okinawans still live in small villages of red tile-roofed houses. Their main food is rice, but they also eat much pork. Most village people farm or fish for a living.

The University of the Ryukyus, in Naha, is Okinawa's major institution of higher education. About 225,000 students attend the prefecture's elementary, junior high, and high schools.

Land and climate. Okinawa is 67 miles (108 kilometers) long and from 2 to 16 miles (3 to 26 kilometers) wide. Mountains and jungle cover the northern part of the island. The southern part has low, rocky hills. Most of the people live in the south.

Okinawa has a subtropical climate. The average daily temperature in Naha is 72 °F (22 °C) the year around. Rainfall averages about 83 inches (211 centimeters) yearly, most of it falling in the typhoon season, from April to October.

Economy. Before World War II, Okinawa was a poor agricultural island. Today, it has one of the highest per capita (per person) incomes in East Asia. Its chief crops include pineapples, rice, sugar cane, and sweet potatoes.

Tourism has become the island's main industry. Most of the tourists come from other parts of Japan to enjoy Okinawa's warm climate and natural beauty.

Okinawan craftworkers make ceramics, lacquerware, and woven and dyed cloth. A pottery kiln in Naha has been operating since the 1600's. Okinawan arts and crafts are prized by art collectors, especially in Japan.

History. Japan and China both claimed Okinawa and the rest of the Ryukus until 1874, when China recognized Japan's rule. For the history of the island before that time, see the article on Ryukyu Islands.

One of the bloodiest campaigns of World War II was fought on Okinawa between U.S. and Japanese troops. The Americans landed on the island on April 1, 1945, and conquered it in late June. During the fighting, more than 90 percent of the island's buildings were destroyed. See World War II (Closing in on Japan).

The peace treaty that ended the war gave the United States control of the Ryukyu Islands. In 1950, the United States began to grant some self-rule to the Ryukyuan. It returned the northern Ryukus to Japan in 1953 but kept Okinawa and the southern islands. The United States built military bases on Okinawa after the Chinese Communists gained control of China in 1949 and the Korean War broke out in 1950.

During the 1950's and 1960's, many Okinawans demanded that the island be returned to Japanese rule. The United States returned the island to Japan in 1972, under an agreement between the two nations. U.S. military bases remain on Okinawa, but nuclear weapons may not be kept on the island without Japan's consent. In 1996, the United States announced that within the coming years it would return to Okinawa 20 percent of the land held by the U.S. military.

David L. Howell
Granite mounds rise in Quartz Mountain State Park near Lugert. The state's varied landscape includes rugged hills and mountains, vast plains, green forests, and fertile farmlands.

Oklahoma  

*The Sooner State*

Oklahoma is a major fuel and food producing state in the southwestern part of the United States. Thousands of oil and natural gas wells dot the Oklahoma landscape. Oil pumps operate even on the front lawn of the State Capitol. Millions of white-faced beef cattle graze on Oklahoma's flat plains and low hills. Fertile fields produce vast crops of wheat.

Service industries and manufacturing are also important in Oklahoma. The state's location midway between the east and west coasts makes it an important transportation, communication, and distribution center. Oklahoma's manufacturing plants turn out large amounts of aerospace equipment, automobiles, electronic products, machinery, and tires.

The development of Oklahoma's vast natural resources began with the Indians. In the 1800's, the United States government made most of the region a huge Indian reservation. The Indians established separate nations, with their own governments and their own schools. The name Oklahoma is a combination of two Choctaw Indian words—okla, meaning people, and homma, meaning red.

The government first opened Oklahoma to white settlement during the late 1880's. Oklahoma became known as the *Sooner State* because some settlers were there "sooner" than the land was opened. It is also called the *Boomer State*, after the promoters who "boomed" white settlement. The land was settled rapidly, and whites soon far outnumbered the Indians.

During the early 1900's, the farms and ranches of Oklahoma were fertile and productive. In the 1930's, however, a long dry period and low farm prices brought disaster to the farmers. Large numbers of farmers and other workers left the state, and the population of Oklahoma dropped.

Both these periods of Oklahoma history have become famous. The story of the state's farmers and cattlemen in territorial days is told in the musical play *Oklahoma!* The title song from the play became Oklahoma's state song. John Steinbeck's famous novel *The Grapes of Wrath* included a fictional, but widely accepted, description of the drought of the 1930's.

Today, farmers protect their land from drought with modern soil and water conservation methods. The state's oil and gas wells continue to yield their valuable products, and the state is working to attract new industries. Oklahoma City, the state capital and largest city in population, is one of the largest cities in area in the United States. It covers about 647 square miles (1,676 square kilometers).

---

Interesting facts about Oklahoma

**Downtown Guthrie** has 100 buildings—about 90 per cent of the downtown area—on the National Register of Historic Places. Guthrie was the first capital of Oklahoma. But in 1910, the capital was moved to Oklahoma City. The booming town suddenly became quiet. Buildings erected during the days of early statehood were preserved and older buildings were not torn down to make room for newer ones. Thus, the town became a treasure of historical architecture. A restoration project in the 1980s brought the town back to life as an example of turn-of-the-century architecture.

The **first automatic parking meter** was installed in Oklahoma City on July 16, 1935.

**Oklahoma City** was barren prairie on the morning of April 22, 1889, but its population numbered more than 10,000 by nightfall. That day unassigned land was opened to settlement.

**Oklahoma is a major United States center of Indian culture.** The state has a large and varied Indian population. More than 60 different Indian tribes live in Oklahoma.

**The Oklahoma State Capitol** is the nation's only statehouse with working oil wells on its grounds. The wells were drilled after the capitol was built, and the state owns the mineral rights to its grounds.

**Indian culture**

Oklahoma City is the capital and largest city of Oklahoma. Modern buildings stand close together in the downtown section of the city. *Left:* Myriad Gardens, in the foreground, provides open space in the crowded downtown area.
Oklahoma in brief

Symbols of Oklahoma
The state flag, adopted in 1925, displays an Osage warrior's shield decorated with eagle feathers. Crossing the shield are two symbols of peace—an olive branch and a peace pipe. On the state seal, adopted in 1907, an Indian and a white frontiersman shake hands before the figure of Justice to show the cooperation of the people of Oklahoma. The large star displays symbols of the Five Civilized Tribes, which moved to the region in the 1800s.

General information
Statehood: Nov. 16, 1907, the 46th state.
State abbreviations: Okla. (traditional); OK (postal).
State motto: Labor Omnia Vincit (Labor Conquers All Things).
State song: "Oklahoma!" Words by Oscar Hammerstein II; music by Richard Rodgers.

Land and climate
Area: 69,903 sq. mi. (181,048 km²), including 1,224 sq. mi. (3,171 km²) of inland water.
Elevation: Highest—Black Mesa, 4,973 ft. (1,516 m) above sea level. Lowest—287 ft. (87 m) above sea level along the Little River in McCurtain County.
Record high temperature: 120 °F (49 °C) at Alva on July 18, 1936; at Altus on July 19 and Aug. 12, 1936; at Poteau on Aug. 10, 1936; at Tishomingo on July 26, 1943; and at Tipton on June 27, 1994.
Record low temperature: −27 °F (−33 °C) at Vinita on Feb. 13, 1905, and at Watts on Jan. 18, 1930.
Average July temperature: 82 °F (28 °C).
Average January temperature: 37 °F (3 °C).
Average yearly precipitation: 33 in. (84 cm).

Important dates
La Salle claimed Oklahoma as part of French Louisiana.
The U.S. government established Fort Gibson and Fort Towson, the region's first military posts.

1541 Francisco Vásquez de Coronado crossed western Oklahoma in search of gold.
1682 The United States bought the Oklahoma region, except the Panhandle, as part of the Louisiana Purchase.
1803 1824 The U.S. government established Fort Gibson and Fort Towson, the region's first military posts.

Oklahoma became the 46th state on November 16.

1893 1907 1928 1990

The Cherokee Outlet was opened to white settlement, creating Oklahoma's greatest land rush.

The Oklahoma City oil field opened.

Oklahoma became the first state to pass term limits on members of its state Legislature.
**Population.** The 2000 United States census reported that Oklahoma had 3,450,654 people. The state's population had increased about 10 percent over the 1990 census figure, 3,145,585. According to the 2000 United States census, Oklahoma ranks 27th in population among the 50 states.

Approximately three-fifths of the people live in the state's five metropolitan areas (see Metropolitan area). These metropolitan areas, in order of population, are Oklahoma City; Tulsa; Lawton; Enid; and Fort Smith, Arkansas, which extends into Sequoyah County in Oklahoma. For the populations of the five metropolitan areas, see the Index to the political map of Oklahoma in this article.

Oklahoma has about 20 cities with populations of over 20,000 people. The majority of these cities are located near Oklahoma City or Tulsa. Oklahoma City is a rapidly expanding center of industry and trade. Tulsa started as a Creek Indian village in the early 1800's. The city boomed after oil was discovered in nearby Red Fork in the early 1900's. Norman, the state's third-largest city, is the home of the University of Oklahoma. Lawton serves Fort Sill, a neighboring military center.

Oklahoma's largest population groups include people of German, Irish, American Indian, and English descent. American Indians make up about 8 percent of the population.

**Schools.** The first schools in Oklahoma were established for the Indians in the 1820's by missionaries. By the late 1840's, several tribes, including the Cherokee and the Choctaw, had established their own advanced educational systems. Schools for white children were first established in Oklahoma in 1890. Oklahoma's present school system is headed by an elected superintendent of public instruction. The superintendent works with a board of education whose members are appointed by the governor. The U.S. government maintains two boarding schools to assist in the education of Indian children. By law, children from age 5 through age 17 must attend school. For the number of

**Population density**

About half the people of Oklahoma live in the metropolitan areas of Oklahoma City and Tulsa. Western Oklahoma, including a narrow strip called the Panhandle, is more thinly populated.

---

**Downtown Tulsa** includes Bartlett Square, a popular outdoor gathering place. Tulsa, Oklahoma's second largest city, lies along the Arkansas River in the northeastern part of the state.
students and teachers in Oklahoma, see Education table.

Libraries. Oklahoma has about 200 public libraries and about 45 college and university libraries. The first public library in Oklahoma was founded in Guthrie in 1901.

The Oklahoma Department of Libraries and the library division of the Oklahoma Historical Society are both located in Oklahoma City. The University of Oklahoma Library in Norman has the DeGolyer collection on the history of science and technology, the Bass Business History collection, and a collection of materials on Western history.

Museums. Oklahoma's museums own many fine collections on Indian history and art. The Thomas Gilcrease Institute of American History and Art, which is located in Tulsa, is devoted largely to Indian history and art. The Woolaroc Museum near Bartlesville owns one of the world's finest collections of Indian blankets. Lawton is the home of the Museum of the Great Plains. The Southern Plains Indian Museum and Crafts Center is located in Anadarko.

The Oklahoma State Museum of History is in Oklahoma City. The National Cowboy and Western Heritage Museum, also in Oklahoma City, features art of the American West. In addition, it houses the Rodeo Hall of Fame, the Hall of Great Westerners, and the Hall of Great Western Performers.

The Kirkpatrick Science and Air Space Museum at Omniplex in Oklahoma City includes exhibits that visitors are encouraged to touch and explore. The Philbrook Museum of Art in Tulsa displays paintings from the Italian Renaissance and collections of Asian art. Fort Sill, a military center near Lawton, has an artillery museum that displays unusual weapons.

Universities and colleges

This table lists the universities and colleges in Oklahoma that grant bachelor's or advanced degrees and are accredited by the North Central Association of Colleges and Schools.

For campuses, see Oklahoma, University of.

*Campuses at Stillwater and Tulsa.

Oklahoma State University, located in Stillwater, was founded in 1890. The university library, shown in this photograph, stands in the central part of the campus.

The Philbrook Museum of Art in Tulsa is known for its beautiful gardens. The museum's collections include paintings from the Italian Renaissance as well as Asian art.
Visitor's guide

Will Rogers, the famous Oklahoma cowboy humorist, once said: "There ought to be a law against anybody going to Europe until they have seen the things we have in this country." Rogers may have been thinking of some of the scenic spots in his home state. Oklahoma's attractions include beautiful natural settings, Indian villages, and striking modern buildings.

Many Oklahoma towns and cities hold annual celebrations to honor Indian and pioneer days. One of the most popular annual events in Oklahoma is the "Trail of Tears" outdoor drama. This play takes place in an 1,800-seat amphitheater in Tahlequah. "Trail of Tears" is performed every night, except Sunday, from early June through Labor Day.

Places to visit

Following are brief descriptions of some of Oklahoma's many interesting places to visit:

**Cherokee Heritage Center**, southeast of Tahlequah, includes the Tsa-La-Gi Ancient Village, a re-creation of an Indian village. Cherokee Indians give tours during the summer months.

**Creek Capitol**, in Okmulgee, is the building from which Creek Indians ruled their republic.

**Fort Sill**, a military center near Lawton, includes three historical sites—Stone Corral, Old Guardhouse, and an artillery museum. The fort was established in 1869.

**National Cowboy & Western Heritage Museum**, in Oklahoma City, displays famous paintings and sculptures of the American West. The center includes the Rodeo Hall of Fame and a re-creation of an old pioneer town.

**National Softball Hall of Fame**, in Oklahoma City, has a hall of fame, paintings, and historical displays.

**Oklahoma City National Memorial**, in Oklahoma City, honors the victims, survivors, and rescuers of the bombing of the Murrah Federal Building in 1995.

**Thomas Gilcrease Institute of American History and Art**, in Tulsa, is an art gallery and library. Exhibits include many paintings on the history of the American West.

**Washita Battlefield**, near Cheyenne, marks the site of an 1868 Indian fight. U.S. cavalry under Lieutenant Colonel George A. Custer surprised the camp of Chief Black Kettle. Custer's men killed or wounded more than 100 Cheyenne Indians, including women and children.

**Will Rogers Memorial**, in Claremore, contains paintings, manuscripts, and other personal belongings of the Oklahoma born humorist Will Rogers. Rogers is buried at the site.

**Woolaroc Museum**, southwest of Bartlesville, displays over 55,000 historical exhibits. Much of its collection deals with the history of the Southwest, including paintings by artists Frederic Remington and Charles Russell.

**National Recreation Area and Forest**. The Chickasaw National Recreation Area lies in south-central Oklahoma. The area has six developed campgrounds for public use. It also has facilities for swimming and boating at the Lake of the Arbuckles. Two sections of the Ouachita National Forest are located in southeastern Oklahoma.

**State parks**. Oklahoma has 58 state parks and 5 state resorts that offer a wealth of water sports, hiking, camping, and other recreational activities. For information about Oklahoma's state parks and resorts, write: Oklahoma Tourism, P.O. Box 60789, Oklahoma City, OK 73146.
Annual events

January-April
International Finals Rodeo in Oklahoma City (January); An Affair of the Heart in Oklahoma City (February); Bullmanza in Guthrie (February); Chocolate Festival in Norman (February); Azalea Festival in Muskogee (April); Eighty-Niner Day Celebration in Guthrie (April); Festival of the Arts in Oklahoma City (April); Prince of Peace Easter Pageant in Lawton (April).

May-August
Fried Onion Burger Day Festival in El Reno (May); Kolache Festival in Prague (May); Strawberry Festival in Stilwell (May); Ki-amiichi Ow-Chito Festival of the Forest in Broken Bow (June); OK Mozart Festival in Bartlesville (June); Pawnee Bill Wild West Show in Pawnee (June); Red Earth in Oklahoma City (June); Discoveryland's "Oklahoma!" in Tulsa (June-August); American Indian Exposition in Anadarko (August); Annual Rodeo and Old Cowhand Reunion in Freedom (August); BOK/Williams Jazz on Greenwood in Tulsa (August).

September-December
Cherokee Strip Celebration in Enid (September); Oklahoma State Prison Rodeo in McAlester (September); State Fair of Oklahoma in Oklahoma City (September); Tulsa State Fair in Tulsa (September-October); Robbers Cave Fall Festival in Wilburton (October); Will Rogers Days in Claremore (November); Festival of Light in Chickasha (November-December); Territorial Christmas Celebration in Guthrie (November-December).
Land and climate

Land regions. Oklahoma has 10 main land regions. These regions are (1) the Ozark Plateau, (2) the Prairie Plains, (3) the Ouachita Mountains, (4) the Sandstone Hills, (5) the Arbuckle Mountains, (6) the Wichita Mountains, (7) the Red River Region, (8) the Red Beds Plains, (9) the Gypsum Hills, and (10) the High Plains.

The Ozark Plateau extends into the northeastern part of Oklahoma from Missouri and Arkansas. This hilly region has swift streams and steep-sided river valleys. The areas between the river valleys are broad and flat. Steep bluffs have been formed where streams cut into the plateau.

The Prairie Plains include the land west and south of the Ozark Plateau. Farming and cattle ranching are the most important activities in this region. The Arkansas River Valley, east of Muskogee, produces such vegetable crops as spinach, snap beans, and carrots. Most of the state’s coal and large amounts of petroleum come from this region.

The Ouachita Mountains rise in the southeastern part of the state on the border between Oklahoma and Arkansas. These mountains are a series of high sandstone ridges that form the roughest land surface in Oklahoma. The ridges run in a general east-west direction. They include Blue Bouncer, Buffalo, Jackfork, Kiamichi, Rich, and Winding Stair. The narrow valleys between the ridges have spring-fed streams. Lumbering is the region’s most important industry.

The Sandstone Hills region extends south from the border with Kansas to near the Red River in southern Oklahoma. It is a region of hills 250 to 400 feet (76 to 120 meters) high. Many areas are covered with blackjack and post oak forests. Much of the early Oklahoma oil development took place in these hills. The Sandstone Hills region still has important oil fields. Farming is also important there.

The Arbuckle Mountains are wedged into an area of 1,000 square miles (2,600 square kilometers) in southeastern Oklahoma. Millions of years ago these were tall mountains. Erosion has worn them down until they now rise only 600 to 700 feet (180 to 210 meters) above the surrounding plains. The erosion uncovered unusual rock formations that are often studied by geology students. The principal formations of this region include conglomerates, granite, limestone, sandstone, and shale. Ranchers use the land to raise cattle.

The Wichita Mountains are rough granite peaks in southwestern Oklahoma. The region has many small artificial lakes. These lakes were created by damming the mountain streams to provide water for animals, and to control soil erosion. Most of this region lies within the Fort Sill Military Reservation and a federal wildlife refuge.

Rugged mesas rise in the Oklahoma Panhandle, which forms part of the High Plains region of northwestern Oklahoma. The rest of this region consists mainly of level grassland.

WORLD BOOK map
The Red River Region is a rolling prairie and forest area. Much of the soil is sandy and very fertile. Farmers in the region grow cotton, peanuts, and vegetables. The Red Beds Plains extend from Kansas to Texas in a wide sweep through the middle of Oklahoma. Soft red sandstone and shale lie under the soil. This gently rolling plain, Oklahoma's largest land region, slopes downward from west to east. The eastern part has forested areas and the western part is mostly grassy. The region has fairly fertile soil. Farmers grow cotton and wheat in the southwestern part. Oil fields have been developed in some parts of the Red Beds Plains.

The Gypsum Hills, west of the Red Beds Plains, extend northward to the High Plains. These hills rise from 150 to 200 feet (46 to 61 meters), and are capped by layers of gypsum 15 to 20 feet (4.6 to 6.1 meters) thick. They are sometimes called the Glass, or Gloss, Mountains, because the gypsum sparkles like glass in the sun. The High Plains, an area of level grassland, occupy the northwestern section. This region, which is part of the vast Interior Plain of North America, includes Oklahoma's Panhandle. The Panhandle is the western portion of Oklahoma, a strip of land 166 miles (267 kilometers) long and 34 miles (55 kilometers) wide. The land of the High Plains rises from about 2,000 feet (610 meters) on the eastern edge of the region to 4,973 feet (1,516 meters).

Average January temperatures

Oklahoma has mild winters. The temperatures are highest in the south and steadily decrease to the north. The northern border is the only part of the state that averages below freezing.

Turner Falls tumbles 77 feet (23 meters) into Honey Creek in the Arbuckle Mountains region of south-central Oklahoma. Erosion has created unusual rock formations in this region.

Average yearly precipitation

Oklahoma has wide differences in precipitation. The amount of precipitation decreases from the east to the west part of the state. Most of the snow falls in northwestern Oklahoma.

Average July temperatures

Oklahoma has hot summers with little variation in temperatures throughout the state. The northeastern corner and the Panhandle area to the west have the coolest summer temperatures.
Rivers and lakes. Oklahoma is drained by two great river systems—the Red and the Arkansas. These systems carry water from the state’s rivers and streams eastward to the Gulf of Mexico. The winding Red River forms Oklahoma’s southern boundary with Texas. Its main tributaries drain southern Oklahoma. These streams include the Blue, Kiamichi, Little, Mountain Fork, and Washita rivers, Cache Creek, and the North Fork of the Red River.

The Arkansas River flows through northeastern Oklahoma. Its principal tributaries flow in a broad, irregular semicircle across the entire width of the state. These include the Canadian and the Cimarron rivers. The Chishkasia, Illinois, Neosho, Poteau, Salt Fork, and Verdigris rivers, which drain northern and eastern Oklahoma, are also important branches.

Oklahoma has more than 200 artificially created lakes and about 100 small natural lakes. Lake Texoma, covering 91,200 acres (36,910 hectares), is the most popular resort center. Part of it lies in Texas. Lake O’The Cherokees is in northeastern Oklahoma. It backs up the waters of the Neosho River for 65 miles (105 kilometers). Lake Eufaula, in the east-central portion, covers over 100,000 acres (40,000 hectares). Fort Gibson Lake, Greenleaf Lake, Lower Spavinaw Lake, Upper Spavinaw Lake, Tenkiller Ferry Lake, and Lake Wister are in eastern Oklahoma. They have resorts for fishing and boating. Other large lakes and reservoirs in Oklahoma include Altus, Canton, Carl Blackwell, Ellsworth, Fort Supply, Foss, Great Salt Plains, Hefner, Heyburn, Hulah, Keystone, Lawtonka, Little River, McAlester, Murray, Oologah, Overholser, and Shawnee.

Plant and animal life. Forests cover about a fifth of Oklahoma. Important trees include ashes, elms, hickories, oaks, pines, sweet gums, and walnut trees. The main commercial forests are in the eastern and southeastern parts of the state.

Service industries, taken together, account for the largest part of Oklahoma’s gross state product—the total value of goods and services produced within a state in a year. Community, business, and personal services form the leading service industry group. Manufacturing and mining also bring in much income. Oklahoma ranks among the leading producers of natural gas and petroleum. Electronic components are the leading manufactured product. Beef cattle are the leading farm product.

Natural resources. Oklahoma has vast reserves of minerals and large areas of fertile soils. Its mineral wealth includes petroleum and natural gas. Large supplies of water and a favorable climate combine with rich soils to make Oklahoma a major food producer. Minerals. The state’s oil reserves are among the largest in the nation. Natural gas is also present in most of the oil fields. Deposits of petroleum and natural gas have been found in nearly every county in Oklahoma.

Rich beds of coal lie in the east-central and northeareastern parts of the state. The mountainous regions have stone and clays. Other mineral resources include limestone, gypsum, salt, and sand and gravel. Helium has

Prairie grasses in Oklahoma provide grazing for millions of cattle. Among these grasses are bluestems, Indian grass, sand grass, and the shorter buffalo grass, grama, and wire grass. Other common prairie plants are mesquite and sagebrush. Dogwoods and redbuds grow in the east, central, and southern areas. Anemones, goldenrods, wild indigos, petunias, phlox, primroses, spiderworts, sunflowers, black-eyed Susans, verbena, and violets grow in all regions of Oklahoma.

Armadillos, coyotes, prairie dogs, and rabbits are common on the plains of Oklahoma. Forest animals include deer, minks, opossums, raccoons, gray and red foxes, and gray and fox squirrels. Common birds in the state include blue jays, cardinals, crows, doves, meadowlarks, mockingbirds, robins, scissor-tailed flycatchers, and house sparrows. Fishes in Oklahoma’s waters include bass, buffalo fish, carp, catfish, crappie, drumfish, paddlefish, and sunfish.

Climate. Most of Oklahoma has a warm, dry climate. Northwestern Oklahoma is cooler and drier than the southeastern part. Precipitation (rain, melted snow, and other forms of moisture) varies greatly throughout the state. Average precipitation ranges from 50 inches (130 centimeters) a year in the southeast to 15 inches (38 centimeters) in the western Panhandle. Snowfall ranges from about 2 inches (5 centimeters) a year in the southeast to 25 inches (64 centimeters) in the northwest. The Panhandle gets the most snow.

The average July temperature in Oklahoma is 82°F (28°C), and the average January temperature is 37°F (3°C). The state’s highest temperature, 120°F (49°C), was recorded on four occasions during the summer of 1936—at Alva on July 18, at Altus on July 19 and August 12, and at Poteau on August 10. The same figure was reached at Tishomingo on July 26, 1943, and at Tipton on June 27, 1994. The record low temperature, –27°F (–33°C), was registered at two locations—at Vinita on Feb. 13, 1905, and at Watts on Jan. 18, 1930.

*CSP = gross state product, the total value of goods and services produced in a year. Figures are for 1998.

An oil derrick rises from the Oklahoma plains, symbolizing the importance of petroleum to the state’s economy. Oklahoma ranks among the leading oil-producing states.

been found in the natural gas of the Panhandle. Soil varies from the fertile deposits in the river valleys to the unproductive shale and granite of the mountains. Much of the plains and grasslands area has a rich, productive soil. Other areas have poor red clay soil.

Service industries account for the largest portion of Oklahoma’s gross state product. Most service industries are concentrated in the state’s metropolitan areas.

Community, business, and personal services form Oklahoma’s leading industry group in terms of the gross state product. This industry group also employs more people than any other industry in Oklahoma. Community, business, and personal services consist of a variety of economic activities, including private health care, equipment rental companies, telemarketing firms, and repair shops. Companies that rent oil field equipment are important to Oklahoma. Several rental car companies have their national telephone reservation systems based in the state.

Wholesale and retail trade ranks second among Oklahoma’s service industries. The wholesale trade of food products, grain, oil and gas, and transportation equipment is important in the state. A leading wholesale food distributor, Fleming Companies, is based in the state. Major types of retail businesses in Oklahoma include automobile dealerships, discount stores, food stores, and service stations.

Government services rank third. Government services include public schools and hospitals, and military bases. The University of Oklahoma Health Sciences Center in Oklahoma City is one of the nation’s leading medical facilities. Tinker Air Force Base, near Oklahoma City, is a major employer in the state.

The finance, insurance, and real estate group ranks next among the service industries. Real estate is important because of the costs of buying and selling homes and other property. Increasing demand for office space in the state’s large cities also benefits the industry. Tulsa and Oklahoma City are the chief financial centers.

Transportation, communication, and utilities rank fifth among service industries in Oklahoma. Pipeline companies transport the state’s huge oil and gas production. American Airlines has a large facility in Tulsa. Telephone companies are the most important part of the communications sector. Utilities supply electric, gas, and water service. More information about transportation and communication appears later in this section.

Manufacturing. Goods produced in Oklahoma have a value added by manufacture of about $17 billion a year. Value added by manufacture represents the increase in value of raw materials after they become finished products.

Computer and electronic equipment is Oklahoma’s leading manufactured product in terms of value added by manufacture. Tulsa is a production center for electronic components and military communication systems. Oklahoma City factories make telephone equipment.

Machinery ranks second among Oklahoma’s manufactured products. Several cities make oil field machinery.
Other types of machinery made in the state include construction machinery, machine parts, and refrigeration and heating equipment.

Other products made in Oklahoma, in order of value added by manufacture, include fabricated metal products, chemicals, transportation equipment, and rubber and plastic products. The Tulsa area produces large amounts of structural metal. Fertilizer ranks among Oklahoma's leading chemical products. Plants in Tulsa make aircraft and aerospace equipment. The Oklahoma City area has a large automobile assembly plant. Factories in Ardmore, Lawton, and Oklahoma City produce tires.

Mining. Natural gas and petroleum are Oklahoma's leading mineral products by far. Oklahoma ranks among the leading states in both natural gas and petroleum production. The heaviest natural gas production occurs in the western part of the state. Two-thirds of Oklahoma's gas is piped to other states. Central Oklahoma is the leading area for petroleum production. Phillips Petroleum, one of the world's largest oil and gas companies, is based in Bartlesville.

Other mineral products include coal, crushed stone, iodine, and sand and gravel. LeFlore County produces the most coal. Limestone quarries in northeast and south-central Oklahoma provide much of the crushed stone. Oklahoma is the only state that produces iodine. Woodward County produces most of it. Sand and gravel come mainly from pits near Oklahoma City and Tulsa.

Agriculture. Farmland covers about three-fourths of Oklahoma. The state has about 83,000 farms and ranches. The production of beef cattle is the leading source of agricultural income, and Oklahoma is one of the country's most important sources of beef. The state has more than 5 million beef cattle.

Cattle are raised in the Oklahoma range, but ranching has become a modern business. Many ranchers graze their cattle on the range for a time, and then take them to feed lots. A feed lot is an enclosed area where cattle are fed to fatten them for market. These animals do not need to search for feed, so they gain weight more rapidly than range cattle and bring higher prices. Other important livestock income comes from chickens, eggs, hogs, milk, turkeys, and farm-raised catfish.

Winter wheat is the state's most valuable field crop, and Oklahoma is a leading wheat-growing state. Wheat fields are harvested early each summer by lines of combines. Hay ranks second in value among Oklahoma's crops. Other important crops include corn, cotton, grain sorghum, peanuts, and soybeans. Eastern and central Oklahoma produce peaches and pecans. Greenhouse and nursery products are an important source of income.

Electric power. Coal-burning plants provide about 60 percent of Oklahoma's electric power. Plants that burn natural gas supply about 33 percent of the electric power. Hydroelectric plants provide most of the rest.

Transportation. Oklahoma has over 112,000 miles (180,000 kilometers) of roads and highways. Oklahoma has an extensive system of toll highways, including the Turner Turnpike, which links Oklahoma City and Tulsa.

Manufacturing computer components is an important economic activity in Oklahoma. The employee shown here is monitoring the production of circuit boards at a plant in Norman.

Beef cattle graze in a field of tall grass near Cleo Springs. The production of beef cattle is Oklahoma's leading source of agricultural income.
Several rail lines provide freight service in Oklahoma. The state’s first railroad was the Missouri-Kansas-Texas Railroad, called the “Katy.” It was built across Oklahoma to Denison, Texas, from 1870 to 1872. Passenger trains connect Oklahoma City with Fort Worth, Texas. Oklahoma City and Tulsa have the state’s major commercial airports. Tulsa and Muskogee are Oklahoma’s chief ports. The McClellan-Kerr Arkansas River Navigation System links these two port cities with Mississippi River ports.

About 35,000 miles (56,000 kilometers) of pipelines carry Oklahoma’s oil, natural gas, and refined products to other states. Most of the pipelines run through central Oklahoma from southwest to northeast.

**Constitution.** Oklahoma has about 200 newspapers, including about 25 dailies. The first newspaper, the Cherokee Advocate, was published in Tahlequah in 1844. It was printed in both English and Cherokee. Today, the largest papers are The Daily Oklahoman of Oklahoma City and the Tulsa World. About 90 periodicals are published in the state.

Station WKY in Oklahoma City was the first commercial radio station in Oklahoma. It went on the air in 1921. The state’s first television stations, KTVY in Oklahoma City and KOTV in Tulsa, began regular broadcasts in 1949. Today, Oklahoma has about 20 television stations and 150 radio stations. Cable television systems and Internet providers serve many Oklahoma communities.

**Government**

**Constitution.** The Oklahoma Constitution was adopted in 1907, the year Oklahoma became a state. It may be amended by a majority vote of the people. Amendments may be proposed by the Legislature or by petitions from the voters. A constitutional convention may be called by the Legislature, subject to voter approval. The Constitution contains initiative and referendum clauses that allow the voters to propose and pass laws directly (see Initiative and Referendum).

**Executive.** The governor is elected to a four-year term and may serve an unlimited number of terms, but not more than two terms in a row. The governor appoints the secretary of state and the heads of the chief revenue and budget departments. Some department heads are chosen by a board or by a commission. The lieutenant governor, attorney general, treasurer, auditor and inspector, superintendent of public instruction, insurance commissioner, labor commissioner, and corporation commissioners are all elected to serve four-year terms.

**Legislature** of Oklahoma consists of a Senate with 48 members and a House of Representatives with 101 members. Each senator and representative is elected from a separate district. Senators are elected to four-year terms and representatives to two-year terms. Each senator and representative is limited to no more than 12 total years of elected service as a state legislator. The Legislature meets in annual sessions that begin on the first Monday in February. In odd-numbered years, the Legislature also meets on the first Tuesday after the first Monday in January to verify election results.

**Courts.** The Oklahoma Supreme Court has 9 justices. They select a chief justice from their group. The governor appoints the justices with the advice of a judicial nominating commission. At the first general election following the appointment, voters decide on nonpartisan ballots whether to retain or dismiss the justice. A vote of retention means the justice may then serve a six-year term. The state also has a Court of Civil Appeals with at least 12 judges and a Court of Criminal Appeals with 5 judges. All of these judges are chosen in the same way that Supreme Court justices are selected.

**Local government** in Oklahoma operates in 77 counties.

The Oklahoma House of Representatives meets in the House chambers in the State Capitol in Oklahoma City.
counties and about 590 cities and towns. The counties have three commissioners, each elected from a separate district. Most cities and towns use the mayor-council or council-manager form of government. Cities of over 2,000 population can adopt and amend their own charters, and thus can take some control over their affairs. 

Revenue. State taxes, including money from licenses, permits, and fees, provide more than half of the state government's general revenue (income). Major sources of tax revenue include a sales tax, a personal income tax, and a severance tax on petroleum and natural gas production. Most of the rest of the revenue comes from bond sales and U.S. government programs. 

Politics. Oklahoma was once almost solidly Democratic. The state began to develop a two-party system during the 1960's. Oklahoma voters elected the state's first Republican governor in 1962. Oklahomans have favored Republican candidates in most presidential elections held since 1948. For Oklahoma's voting record in presidential elections, see Electoral College (table). 

History 

Early days. Before white people came, bands of Indians roamed the plains of the region that now includes Oklahoma. The Indians followed the huge herds of buffalo that grazed on the grasslands. The tribes included the Arapaho, Caddo, Cheyenne, Comanche, Kiowa, Osage, Pawnee, and Wichita. Europeans first reached the Oklahoma region in 1541. That year, the Spanish explorer Francisco Vásquez de Coronado led an expedition from Tiguex, N. Mex. He reached what is now Oklahoma. Later the same year, Hernando de Soto, another Spaniard, probably entered the area. Both Coronado and De Soto were searching for gold, but they found none. 

In 1682, the French explorer Robert Cavelier, Sieur de La Salle, traveled down the Mississippi River. He did not reach the Oklahoma area. However, he claimed for France all the land drained by the Mississippi, including the Oklahoma region. Soon afterward, other French explorers and traders entered the Oklahoma area. 

American ownership. France claimed the Oklahoma region as part of Louisiana until 1762, when France ceded Louisiana to Spain. Napoleon regained the province for France in 1800, but he needed money to fight wars in Europe. In 1803, he sold Louisiana to the United States (see Louisiana Purchase). 

Congress reorganized the administration of Louisiana several times. The section that included present-day Oklahoma was first called the District of Louisiana. In 1805, it became the Louisiana Territory. Seven years later, in 1812, the Missouri Territory was organized from the Louisiana Territory. In 1819, the United States settled several boundary disputes with Spain. As a result, the present Oklahoma Panhandle, one of the disputed areas, was given to Spain. The rest of Oklahoma became part of the Arkansas Territory, which was created in 1819. Miller Court House (in present-day McCurtain County), Salina, and Three Forks were among the first white settlements established in Oklahoma. 

The Indian nations. After 1819, the federal government began prodding the Indian tribes in the southeastern United States to move to the Oklahoma area. The tribes—the Cherokee, Chickasaw, Choctaw, Creek, and Seminole—had lived in close contact with white people for more than a hundred years. They adopted many of the habits and customs of the whites, and became known as the Five Civilized Tribes. 

In the early 1800's, Oklahoma was largely unoccupied. In 1824, to prepare the area for the Indian migration, the U.S. Army built Fort Towson and Fort Gibson. The government soon forced the five tribes to give up most of their eastern lands and begin the move west. 

Between 1830 and 1842, sad processions of Indians moved into the hills and grasslands of eastern Oklahoma. Thousands died along the way. The Indians who moved included the Cherokee, who called their own trip the Trail of Tears. This term is sometimes used to refer to the removal of the other tribes as well. 

The immigrant Indians were given the right to all of present-day Oklahoma except the Panhandle. Each of the five tribes formed a nation. By treaties, the United States promised to protect the Indian nations. The government guaranteed that the Indians would own their lands "as long as grass shall grow and rivers run." Each Indian nation established its own legislature, courts, and written laws, and built its own capital. Most settlements were in the eastern part of the region, but the Indians made trips to the west to hunt buffalo. 

After the first hard years, the Indians began to build schools and churches, clear land, and operate farms and ranches. They were protected from white settlement by their treaties, so the general westward movement of the pioneers passed them. 

The Civil War (1861-1865) destroyed the prosperity and protection the Indians enjoyed. The Five Civilized Tribes had come from the South, and many of the Indians owned slaves. Delegations from Texas and Arkansas urged the Indians to join the Confederacy. In 1861, a Confederate military leader, Albert Pike, made treaties of alliance with some of the tribes. These tribes included some Plains Indians who had moved into the area. At first the Cherokee leader, Chief John Ross, tried to avoid taking sides. But after the Confederates won a battle near the Cherokee border, at Wilson's Creek in Missouri, Ross pledged the Cherokee to the South. Pike then recruited and led a brigade of Indians to fight for the South. One Cherokee, Stand Watie, became a Confederate brigadier general. Other Indians, however, fought for the Union. 

After the Civil War, Congress forced the Five Civilized Tribes to give up the western part of their land because they had supported the South. Some of this land was given or sold to other Indian tribes. 

The land that bordered the Indian Territory filled rapidly with settlers. Soon there was no more free or cheap land available. The whites wanted to use the fertile Indian lands. During the late 1860's, many cattlemen drove their herds across Oklahoma on their way from Texas to the Kansas railroad centers. Some cattle ranchers paid the Indians for grazing rights, but others did not. From 1866 to 1885, over 6 million longhorn cattle crossed the
Indian lands. The East Shawnee, West Shawnee, Chisholm, and Western trails were the leading routes. In 1883, an association of cattle ranchers leased more than 6 million acres (2.4 million hectares) from the Indians for five years. But the U.S. government declared all the leases invalid. President Benjamin Harrison ordered the whites' cattle removed in 1890.

The great land rushes. 'Boomers' urged the government to open the land for white settlement. The boomer leaders included C. C. Carpenter, David L. Payne, and William L. Couch. Finally the government yielded. It bought over 3 million acres (1.2 million hectares) from the Creek and Seminole tribes. Authorities declared almost 1,900,000 acres (769,000 hectares) in central Oklahoma open for settlement at noon, April 22, 1889. Thousands of settlers moved to the border to await the opening. The army held them back until a pistol shot signaled the opening. Then a wild race began to claim the best farms and townsites. About 50,000 people had moved into Oklahoma by that evening. In a single day, Guthrie and Oklahoma City became cities of 10,000 persons.

Some settlers, called Sooners, went into the area before the opening to claim the best land. To hide their early entry, many Sooners ran their horses hard on the day of the opening. Then the tired horses would be shown to the pioneers who had followed the rules, to "prove" that the owner had just arrived.

The Territory of Oklahoma was established by Congress in May 1890, with Guthrie as the capital. The same act added the Panhandle to the territory. The Panhandle had become U.S. territory when Texas joined the Union in 1845. President Harrison appointed George W. Steele as the first territorial governor.

During the 1890's, more and more Indian tribes accepted individual allotment of their lands. This meant that individual Indians, not the tribe, owned the land. Land not allotted to tribe members was opened for settlement. In some areas, settlers got their land by run, or land rush. Other land was distributed by a lottery.

The greatest opening occurred on Sept. 16, 1893. That day, the Cherokee Outlet, in north-central Oklahoma, and the Tonkawa and Pawnee reservations were opened. Over 50,000 people claimed land in the 6 1/2 million-acre (2.6 million-hectare) area the first day.

Progress toward statehood. After 1890, maps showed the Oklahoma area as the Twin Territories—Indian Territory and Oklahoma Territory. Indian Territory was the remaining land of the Five Civilized Tribes, plus a small area owned and settled by other tribes. The rest of the region was Oklahoma Territory.

White settlers now wanted the remaining Indian lands. In 1893, Congress created the Dawes Commission to bargain for the land and to dissolve the Indian nations. Agents of the commission helped the tribes incorporate towns and prepare for citizenship. The commission divided the remaining land among members of the tribes. By 1905, commission leaders felt the Indian Territory was ready to become a state.

Leaders of the Five Civilized Tribes called a constitutional convention at Muskogee in 1905 and invited white citizens to take part. At the time, whites in the Indian Territory outnumbered the Indians five to one. The convention adopted a constitution for the proposed state of Sequoyah, and the people approved it in an election. But Congress refused to accept the area as a state. Congress wanted one state to be created from the Twin Territories. In 1906, delegates from both territories met in Guthrie to draw up a constitution.

Early statehood. On Nov. 16, 1907, Oklahoma became the 46th state in the Union. Charles N. Haskell of Muskogee was elected the first governor. The new state had a population of 1,414,177. Guthrie was the first capital. In 1910, Oklahoma City became the capital.

Even before statehood, Oklahoma had become a center of oil production. A small well was drilled near Chelsea in 1889. The first important well was drilled at Bartlesville in 1897. Tulsa became an oil center after the Red Fork-Tulsa field was opened in 1901.

But there were problems, especially among farmers. The prices of farm products were low, and many settlers found they did not have enough land to farm profitably. After the United States entered World War I in 1917, these problems disappeared in the huge demand for Oklahoma's farm and fuel products.

The 1920's. During the 1920's, many of Oklahoma's problems returned. Farm prices dropped again, and economic distress led to unrest. Secret organizations, such as the Ku Klux Klan, stirred into action (see Ku Klux Klan). The Klan won many members all over the state, and controlled or elected many municipal and county officials. But Governor James B. A. Robertson, who served from 1919 to 1923, fought the Klan and refused to allow any state official to join the organization.

In 1923, John C. Walton became governor. He was impeached for abusing his powers. The state legislature removed him from office after only 9 months and 14 days. Among other things, Walton had used the National Guard to prevent a grand jury from meeting. Lieutenant Governor Martin E. Trapp became governor and served until 1927. Trapp was a "hard roads" governor who pushed the construction of all-weather highways. Trapp also backed a law that made it illegal to wear masks at public gatherings. This law helped control the Klan.

Henry S. Johnston became governor in 1927, but he, too, was impeached. After two years in office, Johnston was found guilty of incompetence and removed by the legislature. In March 1929, Lieutenant Governor William J. Holloway became governor.

Important discoveries of oil and gas helped Oklahoma during this period. The huge Oklahoma City field was opened in 1928. It had more than 1,500 producing wells within 10 years. The Greater Seminole area led the nation in production from 1925 to 1929.

The 1930's. The campaign of 1930 was highlighted by the election as governor of one of Oklahoma's most colorful politicians, William H. "Alfalfa Bill" Murray. A former congressman, Murray appealed to the "common folk" to vote for him. After his election, Murray shut down over 3,000 flowing oil wells. The price of oil had been dropping, and Murray wanted to keep some oil off the market to force up the price. After three months, he permitted production to start again.

Oklahoma suffered many hardships during the Great Depression of the 1930's. Business was bad, and farm prices were extremely low. Many banks failed, and people lost their savings. The entire Great Plains region suffered a severe water shortage. Crops failed for lack of
Oklahoma

Historic Oklahoma

The Butterfield stage line ran across Oklahoma on its route from St. Louis to San Francisco. It opened in 1858.

The Chisholm Trail was used to drive millions of cattle across Oklahoma to Kansas during the 1870s.

The huge Oklahoma City oil field was opened in 1928. It had over 1,500 producing wells within 10 years.

Important dates in Oklahoma

1541 Francisco Vásquez de Coronado crossed western Oklahoma in a search for gold.

1682 Robert Cavelier, Sieur de La Salle, claimed Oklahoma as part of French Louisiana.

1762 France gave Louisiana, including the Oklahoma region, to Spain.

1800 France regained Louisiana.

1803 The United States bought the Oklahoma region, except the Panhandle, as part of the Louisiana Purchase.

1819 The Oklahoma region, except the Panhandle, became part of the Territory of Arkansas.

1824 The government established Fort Gibson and Fort Towson, the region's first military posts.

1830-1842 The Five Civilized Tribes moved to Oklahoma.

1870-1872 The Missouri-Kansas-Texas railroad was built across the region.

1872 Oklahoma's first commercial coal was mined near McAlester.

1889 The United States opened part of Oklahoma to white settlement. The region's first producing oil well was drilled near Chelsea.

1890 Congress established the Territory of Oklahoma and added the Panhandle region to it.

1893 Congress established the Dawes Commission to manage the affairs of the Five Civilized Tribes. The Cherokee Outlet was opened to white settlement.

1907 On November 16, Oklahoma became the 46th state to join the Union.

1920 The Osage County oil fields began to produce.

1928 The Oklahoma City oil field opened.

1963 Henry Bellmon became the first Republican governor of Oklahoma.

1990 Oklahoma became the first state to pass term limits on members of its state legislature.

1995 A terrorist bomb blew up a federal government building in Oklahoma City, killing 168 people.
Construction of a number of dams and creation of several lakes began in the mid-1900s. Some of these projects were completed in the 1960s, and others were finished in the 1970s. The lakes were created to increase the state's hydroelectric power and water storage capacities. The new dams and lakes assisted business and political leaders in their efforts to broaden the state's industrial activity. The state government advertised Oklahoma's abundant supplies of fuel, water, and electric power. In addition, the legislature revised the state's tax structure to attract manufacturers. As a result, Oklahoma gained new industries that do not depend on the products of its farms and mines.

The late 1900s. The McClellan-Kerr Arkansas River Navigation System, completed in 1970, made shipping an important activity. The waterway enables barges on the Mississippi River to reach Oklahoma ports on the Arkansas River. Tulsa and Muskogee are important ports on the river system.

Between 1976 and 1980, a strong world demand for energy led to an economic boom in Oklahoma. The state's petroleum and natural gas industries thrived and brought much income to Oklahoma. In addition, rising tourism contributed to the state's economy.

During the early 1980s, however, the prices of oil and gas fell sharply, and the economic boom in the state ended. In addition, a deep decline in agricultural prices helped bring on an economic crisis for thousands of Oklahomans. Hundreds of oil wells shut down, and many farmers lost their farms. The reduction in tax revenue from oil and gas production also led to cuts in public services. Unemployment increased rapidly, and many people left the state in search of jobs.

The economic crisis helped focus attention on the need to further broaden the state's economy. Once again, state leaders emphasized the need to attract new industries that would help lessen Oklahoma's dependence on its traditional mineral and agricultural industries.

In 1982, betting on horse races became legal in Oklahoma. The sale of alcoholic beverages had become illegal in Oklahoma in 1907. In 1939, the state had repealed this prohibition, with certain limitations. Selling beverages of more than 3.2 percent alcohol by the glass remained illegal in such public places as bars and restaurants. In 1984, the state gave each county the right to decide whether to end the restrictions on alcoholic beverage sales within its borders.

In 1990, Oklahomans voted to limit state legislators to no more than 12 total years of elective service. This was the first time any state's voters passed such term limits.

In 1993, a terrorist bomb blew up Oklahoma City's Murrah Federal Building, killing 168 people. The incident was one of the worst terrorist acts in the United States. For details on it, see Oklahoma City (History).

Oklahoma, University of, is a state-supported coeducational institution in Norman, Oklahoma. It has colleges of architecture, arts and sciences, business administration, education, engineering, fine arts, geosciences, law, and liberal studies; and a graduate college. The Health Sciences Center, in Oklahoma City, has colleges of allied health, dentistry, medicine, nursing, pharmacy, and public health. The college of medicine also has a branch in Tulsa. The university grants bachelor’s, master’s, and doctor’s degrees.

Research facilities on the Norman campus include the Center for the Analysis and Prediction of Storms and the Carl Albert Congressional Research Center. The Molecular Medicine Research Center is in Oklahoma City. The University of Oklahoma Press publishes a wide range of scholarly books. The university was founded in 1890.

Critically reviewed by the University of Oklahoma

Oklahoma City (pop. 506,132; met. area pop. 1,083,346) is the capital and largest city of Oklahoma. About 30 percent of the state’s people live in the Oklahoma City metropolitan area. The city ranks as one of the chief centers of oil production in the United States. It is a commercial and manufacturing center of Oklahoma and a distribution point for a large farming area.

Oklahoma City lies on the North Canadian River, near the geographic center of the state. For location, see Oklahoma (political map). White settlers first came to what is now the Oklahoma City area in 1889. The United States government had originally set this land aside for Indians. But the government later opened central Oklahoma for white settlement. On the first day, about 10,000 settlers flocked to a site near the Atchison, Topeka and Santa Fe (now part of the Burlington Northern Santa Fe Corporation) Railway tracks and pitched their tents. This settlement became Oklahoma City. The city’s name came from two Choctaw Indian words—okla, meaning people, and homna, meaning red.

The city covers 647 square miles (1,676 square kilometers), including 14 square miles (36 square kilometers) of inland water. The Oklahoma City metropolitan area consists of six counties—Canadian, Cleveland, Logan, McClain, Oklahoma, and Pottawatomie—and covers an area of about 4,303 square miles (11,145 square kilometers).

The State Capitol stands in a major oil field near the heart of the city. A statue called The Cowboy stands in front of the Capitol (see Oklahoma [picture: The State Capitol]). A well on the Capitol grounds that was drilled to draw oil from beneath the Capitol was long a tourist attraction. It ended production in 1986. Other producing wells are scattered throughout the city.

The Oklahoma City metropolitan area consists of six counties—Canadian, Cleveland, Logan, McClain, Oklahoma, and Pottawatomie—and covers an area of about 4,303 square miles (11,145 square kilometers).

The State Capitol stands in a major oil field near the heart of the city. A statue called The Cowboy stands in front of the Capitol (see Oklahoma [picture: The State Capitol]). A well on the Capitol grounds that was drilled to draw oil from beneath the Capitol was long a tourist attraction. It ended production in 1986. Other producing wells are scattered throughout the city.
The city's Myriad Convention Center is one of the leading convention sites in the United States. The 36-story Liberty Bank Tower is the city's tallest building.

About 97 percent of the city's people were born in the United States. African Americans make up about 15 percent of the city's population. About 10 percent of the people are Hispanics, 4 percent are American Indians, and 3 percent are Asians.

**Economy.** The leading industries of Oklahoma City produce automobile assemblies, construction equipment, electronic equipment, food products, and petroleum products. Other Oklahoma City products include building materials, cottonseed oil, iron and steel products, paper products, telephone equipment, and transportation equipment. About 1,200 manufacturing plants employ 10 percent of the city's workers.

The federal and state governments employ about 20 percent of Oklahoma City's work force. Tinker Air Force Base is the largest single employer. This important repair and supply station for the U.S. Air Force employs about 18,000 civilians. The Federal Aviation Administration has about 3,000 civilian employees in the city.

Much of Oklahoma City's industrial importance results from its location in an area rich in natural resources for both oil production and farming. The area in Oklahoma County has about 980 oil wells and about 200 wells that produce natural gas. The city processes and distributes much of this raw material.

Will Rogers World Airport lies in the southwestern part of the city. Buses, trucks, and freight and passenger trains also serve the city. Oklahoma City has one daily newspaper, The Daily Oklahoman.

**Education and cultural life.** Oklahoma City's public school system includes about 65 elementary schools and more than 20 high schools. The city also has about 30 church-supported and private schools. Colleges and universities in Oklahoma City include Mid-America Bible College, Oklahoma Christian University, Oklahoma City University, and the University of Oklahoma Health Sciences Center. The University of Oklahoma is in nearby Norman. Southern Nazarene University is in nearby Bethany. The University of Central Oklahoma is just north of Oklahoma City, in Edmond. The city's library system consists of a main library and 10 branches.

Oklahoma City has several community theaters. The Oklahoma City Philharmonic Orchestra performs at the Civic Center Music Hall. The National Cowboy & Western Heritage Museum displays paintings and sculptures of the American West. The Oklahoma Museum of Art features European and American paintings and sculptures. The Oklahoma Art Center offers contemporary works by regional and national artists.

The Oklahoma Historical Society Building and Museum has a collection of exhibits tracing the history of Oklahoma. The Kirkpatrick Science and Air Space Museum at Omniplex includes the Hands-On Science Museum, the Kirkpatrick Planetarium, the Air Space Museum, the Kirkpatrick Galleries, and the Kirkpatrick Gardens and Greenhouse. The Omniplex also houses the International Photography Hall of Fame and Museum and the Red Earth Indian Center.

Oklahoma City has 144 parks, which cover about 4,000 acres (1,600 hectares). Lincoln Park, the largest, occupies 632 acres (256 hectares) and includes the Oklahoma City Zoo.

**Government.** Oklahoma City has a council-manager form of government. The voters elect a mayor and eight council members to four-year terms. The council appoints a city manager.

In 1971, the voters elected Patience S. Latting mayor. She became the first woman mayor of a United States city of more than 200,000 people. Sales taxes provide most of the city's revenue.

**History.** Creek and Seminole Indians lived in what is now the Oklahoma City area before white settlers first arrived. In 1889, the government bought the land here from the two tribes. On April 22, 1889, the government opened the area for white settlement, and a great land rush began. By the evening of that day, about 10,000 settlers had arrived there. Oklahoma City was incorporated in 1890. By 1910, it was the state's largest city. Its popula-
tion rose from 10,037 in 1900 to 64,205 in 1910. During that period, four railroads began to serve the city and two meat-packing plants opened. In 1910, Oklahoma City replaced Guthrie as the state capital.

The city's greatest problem during its early years was a lack of water sources. Shortly after 1900, Oklahoma City built its first municipal well. In 1919, it completed its first reservoir, Lake Overholser. Since then, the city has built several more reservoirs.

By 1920, Oklahoma City had 91,295 people. Oil was discovered in the city in 1928, and an oil boom began. Many oil companies built refineries, and the area became a center of the nation's petroleum industry.

Tinker Air Force Base was built in Oklahoma City during World War II (1939-1945). By 1950, the population of the city had risen to 243,504.

Industrial expansion occurred during the 1950's and 1960's. Iron and steel plants were built, and the city also became a center of the electronics industry. Development also took place in downtown Oklahoma City. During the 1960's, the city annexed many surrounding areas, and its area increased from about 310 square miles (803 square kilometers) in 1960 to about 635 square miles (1,645 square kilometers) in 1970. Oklahoma City's population continued to grow. It reached 403,484 by 1980.

Since the late 1960's, Oklahoma City has undertaken several urban renewal projects to replace old buildings and wipe out slums. One of the projects, called the Medical Center Project, was completed in 1978. It includes a dental college, a hospital, a nursing school, and headquarters for the State Health Department.

The Central Business District Project, which included the construction of several office buildings and a convention center, was completed in 1985. The John F. Ken-
of agriculture, arts and sciences, business administration, education, engineering, home economics, veterinary medicine, and a graduate college. It also offers a program in fire protection and safety technology. The school grants bachelor’s, master’s, and doctor’s degrees. It has a two-year technical branch in Okmulgee and one in Oklahoma City and a college of osteopathic medicine in Tulsa. It also offers programs at the university center at Tulsa. The university maintains a number of agricultural experiment stations and a state extension service. It also has Army and Air Force ROTC units. The university was established in 1890 and was opened to students in 1891. Critically reviewed by Oklahoma State University

**Okra, Oh kruh, also called gumbo or okro**, is a plant cultivated for its immature pods. The pods are eaten as a vegetable chiefly in the southern part of the United States. They are typically fried or used as an ingredient in stews or soups.

The okra plant is an annual and must be raised from seed each year. Gardeners plant the seeds in the spring. The okra plant grows 2 to 8 feet (0.6 to 2.4 meters) high. It bears rounded, fine-lobed leaves, and greenish-yellow flowers. The pods on the plant measure from 4 to 6 inches (10 to 15 centimeters) long. However, they sometimes exceed 1 foot (30 centimeters) when fully grown. Okra pods are cooked and canned when they are young and tender.

Okra is a kind of hibiscus and is related to cotton. It is a native of Africa. Okra is raised in large quantities in the southern United States. S.J. Locascio

**Scientific classification.** Okra is a member of the mallow family, Malvaceae. Okra is *Hibiscus esculentus*.

**Olajuwon, oh LY juh wahn,** **Hakeem, ah KEEM** (1963- ), ranks among the greatest centers in the history of the National Basketball Association (NBA). Olajuwon stands 7 feet (213 centimeters) tall. On offense, he is known for his quick, graceful moves and accurate jump shot. Defensively, he is one of the leading shot-blockers in NBA history. Olajuwon led the Houston Rockets to the NBA championship in 1993-1994 and again in 1994-1995. During the 1993-1994 season, he became the first NBA player ever to be named the league’s Most Valuable Player, defensive player of the year, and Most Valuable Player in the play-off finals in the same season.

Hakeem Abdul Olajuwon was born in Lagos, Nigeria. He played soccer and handball as well as basketball in Nigeria. He attended the University of Houston from 1981 to 1984, where he was a star player. The Houston Rockets selected him as the first player in the 1984 draft. Houston traded him to the Toronto Raptors after the 2000-2001 season. Early in his career, his name was spelled Akeem. He then changed it to Hakeem. Olajuwon became a U.S. citizen in 1993. Sam Smith

**Old age** cannot be defined exactly because it does not have the same meaning in all societies. In many parts of the world, people are considered old because of certain changes in their activities or social roles. For example, people may be considered old when they become grandparents or when they begin to do less or different work. In the United States, people are often considered old if they have lived a certain number of years. Many Americans think of 65 as the beginning of old age because United States workers become eligible to retire with full social security benefits at age 65. People in the 65-and-over age group are often called senior citizens. Starting in the year 2003, the age at which a person becomes eligible for full social security benefits will increase gradually until it reaches age 67 in 2027.

Worldwide, the number of people 65 or older is increasing faster than ever before. Most of this increase is occurring in developing countries. In the United States, the percentage of people 65 or older increased from 4 percent in 1900 to about 13 percent in the late 1990’s. In 1900, only about 3 million of the nation’s people had reached 65. By 1998, the number of senior citizens had increased to about 34 million. Population experts estimate that more than 50 million Americans—about 17 percent of the population—will be 65 or older in 2020. The number of elderly people is growing around the world chiefly because more children reach adulthood.

In most parts of the world, women live, on average, longer than men. In the United States in the late 1990’s, life expectancy at birth was 80 years for women and 73 years for men. American women who were age 65 in the late 1990’s could expect to live about 19 additional years. Men who were 65 could expect to live about 16 additional years.

The study of aging and old age is called gerontology. Many universities and colleges offer courses in gerontology for people who wish to provide services for the elderly. Geriatrics is the branch of medicine that deals with old age and its diseases. Most medical schools offer courses in geriatrics.

The rest of this article mainly discusses attitudes toward old age and tells about ways of life of the elderly in the United States. For information on the medical and physical aspects of old age, see the World Book articles on Aging and Geriatrics.

**Attitudes toward old age**

In all societies, old people are generally more respected if they control important resources, such as information, money, or land. In many countries, for exam-
ple, the ability of the elderly to provide information based on their extensive experience gives them a respected position in society. This is particularly true in nonindustrial countries, which have few books or computers to store information. In modern industrial nations, however, many people do not regard the elderly as wiser or more knowledgeable. Also in industrial nations, where income from work is a major resource and where having a job earns a person respect, people may lose status when they retire.

Many beliefs about older people are untrue. Some employers, for example, think that younger workers are more efficient and reliable than older ones. But in many types of jobs, older people are better workers than younger people. The ideas that people become less intelligent as they age and that old people cannot learn new skills are also not true. Some researchers have called the many incorrect ideas about old people ageism.

Ways of life of the elderly

Older people in the United States follow many different ways of life. How a particular older person lives has much to do with how that person lived in earlier years. Important factors include the financial resources the person has accumulated, the interests the person has developed, and the relationships the person has established with other people.

Finances. The most important source of income for many retired workers is Social Security. Workers and their employers pay equal shares of a payroll tax into the Social Security fund, which is administered by the federal government. After the workers retire, they receive a monthly payment from the fund. The amount of their payment is determined by the salary they earned and the number of years they worked. Widows and widowers continue to receive the pension after the death of their spouses. See Social security.

Some retired people also receive a pension from their employer or have their own savings. Most retired people receive less than half as much as they earned while working. But in many cases, their expenses are also lower.

Employment and other activities. The majority of Americans over 65 do not have a job. Only about 15 percent of the men above this age and 8 percent of the women are employed. Under United States law, workers in most jobs cannot be forced to retire because of their age. However, even when employers were still allowed to enforce a retirement age, most people stopped working for other reasons. Health and expected retirement income were, and still are, the chief factors in the decision to retire.

Some senior citizens join private groups for social and recreational activities. These groups include church organizations and senior citizens' clubs. Some elderly people join AARP (formerly the American Association of Retired Persons), the National Council of Senior Citizens, or similar organizations. These groups offer a large number of services, including educational and travel programs, medical insurance, and newsletters. In addition, such organizations also tell politicians about older people's views on medical care, Social Security, and related issues. An organization called the Gray Panthers, whose members include both young and old, works to fight ageism in U.S. society.

The U.S. government provides several programs that enable senior citizens to help other people. For example, the Service Corps of Retired Executives (SCORE) attracts retired business people who enjoy advising community organizations and small businesses. The Foster Grandparent Program (FGP) uses seniors to help care for children. People over 60 may also join the Retired Senior Volunteer Program (RSVP) to work in hospitals, libraries, schools, and other institutions.

Older people seem to have a greater involvement in politics than do members of any other age group in the United States. A higher percentage of elderly people than other individuals vote in elections.

Housing. Most Americans over 65 are closely involved with their families. However, only about one-eighth of all elderly Americans live with a relative other than their husband or wife. A large number of elderly parents and their children prefer the independence and privacy of living in separate dwellings. In other countries, the percentage of elderly parents who live with their children is much higher. In Japan, for example, about two-thirds of all elderly parents live with one of their children.

In the United States, only about 5 percent of the elderly live in a nursing home or other institution. Some of the senior citizens in the United States live in special housing called retirement communities. These communities may consist of apartment buildings, individual houses, or groups of mobile homes. In retirement communities, residents are guaranteed medical care for as long as they live.

Health care. The federal government administers Medicare, a medical insurance program for senior citizens that pays part of their expenses for physicians and hospital care. Medicare also pays a portion of the cost of medical services at home or in a nursing home. However, medical expenses remain a serious problem for many older people and their families, especially if long-term care is needed because of a chronic illness. Finding ways for older people to receive high-quality, long-term care is a major problem facing American policymakers today. See Medicare.

Old Bailey. The common name for the Central Criminal Court in London. The Old Bailey has several courts, and each one holds sessions at least four times a year. It
Old Catholic churches

are a group of Christian churches that split away from the Roman Catholic Church. Most of them were formed by Catholics who opposed the dogma of papal infallibility proclaimed at the first Vatican Council in 1870. This dogma states that the pope is free from error when he speaks as head of the church on matters of faith and morals.

The Catholics who withdrew from the Roman Catholic Church at that time established an independent church. Most of these Catholics lived in Germany, the Netherlands, Switzerland, and the Austro-Hungarian Empire. In 1889, the independent church formed a loose relationship with other dissenting Catholic churches under the terms of an agreement called the Union of Utrecht. Some of these dissenting churches had been established as early as 1724.

Old Catholic churches generally follow Roman Catholic doctrine, though the clergy may marry. The churches encourage Bible study. Marvin R. O'Connell

Old English. See English language (Old English); English literature (Old English literature).

Old English sheepdog is best known for its long hair, "bobbed" tail, and odd, shuffling walk. Its hair hangs down over its eyes. Much brushing is required to keep the dog's long coat neat. The coat serves as excellent insulation. It is gray or blue, often with white markings, or mostly white with gray or blue markings. The dog stands about 22 inches (56 centimeters) high, and weighs from 50 to 65 pounds (23 to 29 kilograms). Critically reviewed by the American Kennel Club

Old North Church is the popular name for Christ Church, which is the oldest public building in Boston. The red-brick structure has a slender white steeple in the Christopher Wren style. Robert Newman hung the lanterns there as a signal from Paul Revere that the British were coming. The tower contains the first set of church bells in the American Colonies, cast in 1744. Storms in 1804 and 1954 toppled the spire. In 1955, it was rebuilt to its original height of 190 feet (58 meters). William J. Reid

See also Boston; Revere, Paul.

Old Spanish Trail. See Santa Fe Trail.

Old Testament is the Christian name for the Jewish Bible. Judaism accepts only the Old Testament as its Bible. Thus, when Jews use the term Bible they mean only those books in the Old Testament. When Christians refer to the Bible, they mean the larger collection that includes the Old Testament and the later New Testament.

Many scholars have replaced the term Old Testament with more neutral names. Two such names are the Hebrew Bible and Tanakh, a word composed of the first letters of three Hebrew words—Torah, Neviim, and Ketubim. These Hebrew words are the names of the three sections of the Hebrew Bible. Of all the possible terms, Old Testament and Hebrew Bible are most often used interchangeably.

The Old Testament emphasizes the idea of a covenant (solemn agreement) between God and the Israelite people. The covenant is based on a belief in God. In the agreement, God promises to reward the people if they observe its conditions and laws and to punish them if they violate its terms. These aspects of the covenant resemble actual historical agreements between ancient kings and the countries they conquered. Much of the Old Testament traces the history of the Israelites to show how well they observed the covenant and how God treated them as a result.

Contents. The contents of both the Jewish and Christian Bibles changed over many centuries. All Christian Old Testaments are still not identical. The Greek Jewish Bible adopted by early Christianity differed from the Hebrew Bible adopted by Judaism. As a result, the Hebrew Bible is not identical in its contents to Christian Old Testaments. In addition, there are many different translations of the Old Testament. There are more Protestant translations than Roman Catholic translations.

The Old Testament accepted by Judaism consists of 24
books. Protestants accept the same books but arrange them differently. Protestants also divide several of the books, increasing the number to 39.

The Roman Catholic Old Testament includes an additional seven books that Protestants consider part of a collection of religious writings called the Apocrypha. Christian and Jewish groups differ in the position of importance they assign to the books of the Apocrypha. Many of these books resemble the Old Testament in form, but they were written later. This article discusses the Old Testament that is shared by the Jewish, Protestant, and Roman Catholic traditions.

The Hebrew Bible is divided into three main sections: the Law, also called the Torah or Pentateuch; the Prophets, or Nebim; and the Writings, or Ketubim. The Christian Old Testament is divided into the Law, or Pentateuch; Historical Books; Wisdom Books; and Prophets. Both Jewish and Christian Bibles accept the books of the Law, Exodus, Leviticus, Numbers, and Deuteronomy as the Law, but sometimes call it by different names.

The Jewish and Christian versions differ on the titles and arrangement of many of the other books. For example, the Hebrew Bible puts Joshua, Judges, Samuel, and Kings in the section called the Prophets, because the books describe the lives and activities of many prophets, including Elijah. The Christian Old Testament classifies these books as Historical Books, because they trace the early history of the Jewish people from the time they settled in Canaan during the 1200's B.C. until the Babylonians conquered the kingdom of Judah in 587 or 586 B.C.

Today, all Bibles also divide Samuel, Kings and Chronicles into two books each: 1 and 2 Samuel, 1 and 2 Kings, and 1 and 2 Chronicles. For a table of the books recognized by Jews, Protestants, and Catholics, see Bible.

Development. The Old Testament was written over a long period. The process was complicated, because much of the material was recited or chanted before it was written down. Scholars disagree about how and when the books were actually written.

The Old Testament's most detailed description of the production of a Biblical book (presumably Jeremiah) appears in chapter 36 of Jeremiah. This passage describes a process that included oral recitations by the prophet and the recording of his prophecies by his secretary. After the king of Judah cut up and burned the scroll, the secretary recorded it again from Jeremiah's memory and added several supplements. Though the Bible does not provide such complete descriptions of the other books, scholars assume that similar processes and stages of editorial activity contributed to their production.

Many parts of the historical and prophetic books were written during the kingdoms of Israel and Judah, from 922 to 586 B.C. Some of the most important prophets and poets lived during the Babylonian Exile, a period of captivity following Babylon's conquest of Judah in 587 or 586 B.C. Many traditions, laws, and historical records were collected and organized at that time. Other books were written after the exile ended in 538 B.C., when many Jews were allowed to return to Palestine.

The Dead Sea Scrolls show that the text of the Hebrew Bible in use today existed over 2,000 years ago. These scrolls include manuscripts of the Hebrew and Greek books of the Old Testament found in caves near the Dead Sea. They date from the 200's B.C. to A.D. 135.

Translations. The entire Old Testament was written in Hebrew, except for some chapters in the books of Daniel and Ezra and a few words in Genesis and Jeremiah. These passages are in Aramaic, a language much like Hebrew. The first translations were oral translations from Hebrew into Aramaic called Targums. In congregations that spoke Aramaic rather than Hebrew, a translator would stand beside the Bible reader in the synagogue and recite Hebrew passages in Aramaic verse by verse as the Bible was read.

In the 200's B.C., Jewish scholars working in Alexandria, Egypt, translated the Torah into Greek. Gradually other sections were added. The complete Greek translation is called the Septuagint. Other translations of Old Testament books followed. The best-known Latin translation was the Vulgate, completed by Saint Jerome in A.D. 405. Jerome's translation was the official Old Testament text of the Roman Catholic Church for centuries.

Old World is a general term applied to the Eastern Hemisphere. The Old World includes the continents of Europe, Asia, Africa, and Australia. But the term Old World is often used to refer just to Europe or to European civilization. See also New World; Hemisphere.

Oldenburg, Claes, klaws (1929—), is an American sculptor who became a leader of the pop art movement during the early 1960's. He is known for his exaggerated, oversized sculptures that represent such familiar objects as ice cream cones, electric plugs, lipstick tubes, and Mickey Mouse.

Using these objects as the single subjects of his works, Oldenburg has created two principal types of sculpture. One of these types consists of sculptures that are made of soft material, thus contradicting the hardness of the actual objects. This soft material is frequently in a bright color that is related to its subject. The second type is made up of huge steel monuments of common objects designed to be placed in landscapes or among buildings (see Des Moines [picture]). By creating these caricatures of everyday objects, Oldenburg changes recognizable objects into abstract forms.

Oldenburg was born in Stockholm, Sweden. He be-
Oldfield, Barney

See also Pop art.

Oldfield, Barney (1877-1946), was the first person to drive an automobile at a speed of 1 mile (1.6 kilometers) per minute. His name became synonymous with speed after he did this in a much-publicized test at Indianapolis on June 13, 1903. His first racing car, the "999," was built by Henry Ford. In it, Oldfield won his first race at Detroit in 1902. In 1910, at Daytona Beach, Florida, he raced a mile at an average speed of 131 miles per hour (211 kilometers per hour), a record then. Berner Eli Oldfield was born in Wauseon, Ohio.

See also Aviation (picture: Airplanes raced against automobiles).

Olds, Ransom Eli (1864-1950), was a pioneer automobile inventor and manufacturer. Two automobiles, the Oldsmobile and the Reo (from his initials), were named for him.

Olds was born in Geneva, Ohio. In 1886, he began experimenting with steam-powered carriages in his father's machine shop in Lansing, Michigan. He later made a four-wheeled steam car that he sold to a firm in India in 1893. It was the first car manufactured in the United States that was sold abroad.

Olds built his first gasoline-powered car in 1896. In 1899, he helped found the Olds Motor Works in Detroit. A lightweight, one-cylinder, low-cost model ($650) was in volume production by 1901. Many thousands of these cars were sold by 1906.

In 1904, Olds left the Olds Motor Works and set up a firm to make Reo cars and trucks. He was president of the Reo Motor Car Company from 1904 to 1924 and later became its chairman.

Many people consider Olds to be the founder of the automobile industry. He built the first automobile factory that used the assembly line manufacturing process. In addition, the success of the Oldsmobile attracted other car manufacturers into the industry and helped make the automobile popular with Americans.

See also Automobile (The Detroit pioneers).

Oleander, *Nerium oleander,* is a popular ornamental flowering shrub. The oleander sometimes grows 15 feet (4.6 meters) tall. It has leathery, lance-shaped leaves and colorful roselike flowers. The two most common varieties have red and white blossoms. The oleander is native to the warm parts of Asia and to the Mediterranean region. Gardeners plant the oleander outdoors in warm climates. However, they grow it indoors in pots and tubs in temperate regions. It is a favorite porch plant in summer.

Gardeners raise the oleander from cuttings. When the cuttings are placed in bottles of water, they will form roots in a few weeks. After the cuttings root, they must be transplanted to moist, rich soil, where they grow well. All parts of the oleander are poisonous to eat.

William S. Judd

Scientific classification. The oleander is in the dogbane family, Apocynaceae. Its scientific name is *Nerium oleander.*

O'Leary, Hazel Rollins (1937- ), served as the United States secretary of energy under President Bill Clinton from 1993 to 1997. She was the first woman and the first African American to hold that post.

Before O'Leary became secretary, she worked for the U.S. Federal Energy Administration and the Department of Energy under Presidents Gerald Ford and Jimmy Carter. In these positions, she was responsible for federal government programs designed to conserve energy and protect the environment. From 1989 to 1993, O'Leary was an executive of the Northern States Power Company, a utility based in Minneapolis, Minnesota.

O'Leary was born Hazel Reid in Newport News, Virginia. She earned a bachelor's degree from Fisk University in 1959 and a law degree from Rutgers University in 1966.

Barbara A. Reynolds

Olefin is a manufactured fiber used widely in the production of carpets and rugs and of thermal apparel, such as jackets and undergarments. The fiber consists of long, chainlike molecules called polymers that are at least 85 percent olefin units by weight. The most common olefin units are polypropylene and polyethylene. Olefin fibers are resilient, lightweight, and resistant to mildew and many chemicals.

Olefin polymers are produced by combining carbon and hydrogen under heat and pressure in the presence of a solvent and a catalyst, a substance that speeds chemical reactions. In the most common method of olefin fiber production, the polymer is melted and extruded (forced through a shaped die), then cooled and spun.

Oligarchy, *AH L uh GAHR lee,* is any type of government in which power is held by relatively few people. An oligarchy may take many different forms. For exam-

The oleander is an ornamental flowering shrub. It produces leathery, lance-shaped leaves and colorful roselike blossoms.
ple, a republic may be an oligarchy if only a few people have the right to vote (see Republic). An aristocracy, in which rulers come from the "best" members of the community, is also a form of oligarchy (see Aristocracy). In most oligarchies, the ruling group has power because of its wealth or military authority.

The term oligarchy traditionally has been seen as the rule of a selfish few over a whole community. However, some political scientists apply the term to all forms of political and social organization, including states, political parties, churches, and corporations.

Oligarchies have existed throughout history. Most ancient Greek city-states were classic examples. In modern times, a number of military dictatorships in Africa, Asia, and Latin America have operated like oligarchies.

Alexander J. Groth

Oligocene Epoch. See Earth (table: Outline of the earth's history).

Oligopoly. See Monopoly and competition.

Oliphant, AHL ih fuhntr, Patrick Bruce (1935--), is a well-known editorial cartoonist. The figures in his cartoons have very exaggerated features, and his work is more biting than that of most other editorial cartoonists. Most Oliphant cartoons include Punk the Penguin, a character that usually comments on the action in the drawings. Oliphant won the Pulitzer Prize for cartooning in 1967.

Oliphant was born in Adelaide, Australia. In 1955, he became the editorial cartoonist of The Advertiser, the Adelaide newspaper. He came to the United States in 1964 to join the Denver Post as editorial cartoonist. From 1975 to 1981, he worked on The Washington Star. Universal Press Syndicate distributes Oliphant's cartoons to about 500 newspapers. Collections of his work have been published in The Oliphant Book (1969) and Four More Years (1973).

Roy Paul Nelson

Olive is the fruit of a tree that grows in subtropical regions. Olives are cultivated chiefly for their oil, which is used in cooking. The fruit is also eaten whole after processing. People have grown olives since prehistoric times. It is thought that the fruit first grew in the eastern Mediterranean basin. Centuries ago, it began to grow wild around the Mediterranean Sea. The Spaniards brought olives to South America, and they were introduced into California in 1769.

Appearance of the fruit and tree. The fruit may be oval or oblong. As it matures, it turns from green to yellow to red to purple-black. It has a smooth skin, and its flesh surrounds a hard pit. Both the flesh and the seed in the pit contain oil, which makes up 10 to 40 percent of the mature fresh fruit's weight. Fresh olives contain oleuropein, a bitter substance that makes them unpleasant to eat before processing. During processing, this substance is largely or entirely removed.

The olive tree's bark and leaves are a soft gray-green, and its trunk becomes gnarled as it ages. Olive trees live longer than most other fruit trees. There are olive trees in Palestine that may be more than 2,000 years old.

A mature olive tree may have as many as 500,000 small flowers. Most of the flowers are imperfect, and fruit cannot grow from them. They give off pollen, which is usually carried from flower to flower by the wind. Most varieties of olive trees bear a large crop one season and a small crop the next.

Cultivation. Parts cut off from an olive tree may take root and grow into new trees. The trees will grow in many types of soil but need good drainage. To produce large fruit, the grower must irrigate and prune the trees, and thin the fruit. Fertilizers that add nitrogen to the soil can increase yields. The olive tree will grow where the climate is hot and dry. But for bearing good fruit, the tree needs a moderate supply of water. The fruit matures from October to January and is injured if the temperature falls below 26 °F (−3 °C). The tree itself is not seriously injured until the temperature falls to 16 °F (−9 °C). The fruit needs much heat to have a good quality when mature. The air must be dry when the flowers blossom, and also when the fruit begins to grow.

Harvesting and preparation for market. Most olive-producing nations grow the fruit primarily for its

An olive tree has a gnarled trunk and grows many small flowers. The tree thrives in warm regions.

Olives are a small, oval or oblong fruit. They are grown chiefly for their oil, which can make up about half the flesh of the fruit.
Olive oil

In the United States, the industry is based on preparing the fruit for eating. Oil is produced as a sideline.

Harvesting olives requires careful handling. Olives grown for their oil may be mechanically harvested. Olives grown for eating must be picked by hand. Workers place the fruit in small boxes and haul it to the processing plant. Fruit that must be shipped over long distances may be placed in barrels of brine.

Olives processed for eating are either green or black. One of three major processing methods may be used: (1) the Spanish, (2) the American, and (3) the Greek.

Most green olives are prepared by the Spanish process. In this process, unripe, yellowish-green olives are placed in lye solution. The lye removes most of the bitter taste of the oleuropein. The olives are washed and then fermented in brine. They are kept submerged continuously to prevent darkening, which can result from exposure to the air. The fermented olives may be pitted and stuffed with such fillings as almonds and pimentos. The fruit is then packed in fresh brine and pasteurized.

In the United States, most black olives are prepared by the American process. This process ripens immature, yellow-to-red olives artificially. The fruit is alternately submerged in lye and exposed to the air until no bitterness remains and the olives have turned brown to black. The fruit is then washed and pickled. After canning, the olives are sterilized at 240°F (116°C).

In the Greek process, ripe, purple-black olives undergo a slow fermentation in brine. During fermentation, the fruit's bitterness decreases until the brine masks it. This process traditionally does not use lye.

Production. Nations along the Mediterranean Sea grow most of the world's olives. Italy and Spain together produce more than half the world output. Greece is also a major olive-growing country. World olive production totals about 11 million tons (10 million metric tons) a year.

The United States olive crop comes entirely from California. Olive trees are cultivated in the southern and central parts of the state. The olive tree also grows along the Gulf of Mexico, but it does not bear fruit there.

George C. Martin

Scientific classification. Olives belong to the olive family, Oleaceae. Their scientific classification is Olea europaea.

See also Forsythia; Olive oil; Spain (picture: Olive orchards).

Olive oil is a fragrant, edible oil made from olives. It is used primarily as a salad dressing and as a cooking oil. It ranges in taste from sweet to bland and consists almost entirely of unsaturated fat (see Fat). Most olive oil has a light greenish-yellow color.

Olive oil is widely used in countries along the Mediterranean Sea. Italy is the world's leading producer of olive oil. Spain and Greece also make large quantities of olive oil. In the United States, it is produced only in California.

Olive oil is made by crushing and pressing ripe olives. Whole olive fruit consists of 10 to 40 percent oil, and the fruit pulp is 60 to 80 percent oil. Producers use hydraulic presses to squeeze the oil out of the fruit under low pressure. This technique, called cold-pressing, generates little heat, and so the oil retains its flavor, color, and nutritional value. Thus, olive oil, unlike most other vegetable oils, needs no further processing before being packaged. In addition, olive oil can be stored for months without refrigeration or danger of spoilage.

Cold-pressing commonly is carried out in several stages, with only some of the oil being extracted at each stage. The process remains basically the same throughout, but the quality of the oil declines with each pressing. In most cases, olives are cold-pressed at 40°F (4°C). Water is added during pressing to make the oil flow better. The oil is later separated from the water in a spinning machine called a centrifuge, or it is skimmed off the water's surface after settling there.

The first pressing gives the highest quality oil, which is usually called virgin olive oil. Virgin olive oil is more expensive than other vegetable oils, so it often is considered a gourmet item.

The lower-quality oils from later pressings are often blended in small amounts with such refined oils as soybean or cottonseed oil. Olive oil that comes from the final pressing is inedible. This oil, called olive residue or olive foots, is used in cosmetics, detergents, soap, medicines, and textiles.

Olivier, Mount of. See Mount of Olives.

Olivier, Oh LiHV ee ay. Laurence (1907-1989), became one of the leading English actors of the 1900's. Olivier was a versatile performer and was especially known for his acting in the plays of William Shakespeare. His film versions of Shakespeare's Henry V (1944), Hamlet (1948), and Richard III (1953) are considered classics. Olivier produced, directed, and starred in all three films. He won an Academy Award as best actor for his performance in Hamlet. Olivier was given a special Academy Award for his work as producer, director, and star of Richard III. In 1979, he received a special Academy Award for his lifetime achievement in motion pictures.

Olivier was born in Dorking. He made his professional stage debut in 1924. His first screen appearance was in 1930. Olivier gained international fame for his romantic roles in Wuthering Heights (1939) and Rebecca (1940). From 1963 until 1973, Olivier served as the first director of the National Theatre of Britain (now the Royal National Theatre).

Olivier was knighted in 1947. In 1970, he became Lord Olivier of Brighton, the first actor in English history to gain international fame for his romantic performance in the 1940 film Rebecca, co-starring Joan Fontaine.

Laurence Olivier gained international fame for his romantic performance in the 1940 film Rebecca, co-starring Joan Fontaine.
be named a baron. His autobiography, Confessions of an Actor, was published in 1982. On Acting (1986) is a series of essays he wrote about his professional life.

Daniel J. Watermeier

Olivine, AHL uh veen, is any of a group of common rock-forming minerals that consist of silicon, oxygen, magnesium, and iron. Olivine occurs primarily in dark igneous rocks, usually as grained masses or embedded crystals. It is generally one of the first minerals to crystalize from dark-colored magma (melted rock material).

Most types of olivine range in color from clear green to yellow-green, but iron-rich varieties may be brown. Olivine is relatively hard and cannot be scratched by a knife. The most common olivine is forsterite, which is rich in magnesium. Clear green olivine used as a gemstone is called peridot (see Peridot).

David F. Hess

Olmec Indians, OHL mehk, developed what may have been the earliest civilization in the Americas. The Olmec civilization flourished between about 1200 and 400 B.C. The most important centers of Olmec culture were on the Mexican Gulf Coast, in what are now the southern Mexican states of Veracruz and Tabasco. By 400 B.C., the Olmec's sophisticated artistic style had spread over much of Middle America, from central Mexico to El Salvador. Some scholars have also recognized Olmec influences in the artwork and religious practices of many later Middle American cultures, including those of the Maya and the Aztec.

The Olmec lived near rivers in small thatched houses. They fished in the rivers and farmed lands made fertile by river flooding. The Olmec used a calendar and an early form of writing. At a number of sites, archaeologists have found large earthen mounds and uncovered ruins at what are believed to be Olmec religious centers. Artworks found at these sites include huge carved-stone heads that weigh up to 36,000 pounds (16,300 kilograms). The Olmec transported some of these gigantic stones more than 50 miles (80 kilometers) to the sites where the sculptures were discovered. Other objects found at the sites include mirrors of polished iron ore, carvings with both animal and human features, and groups of small stone figures arranged to represent religious ceremonies.

William G. Autry

See also Maya (History); Sculpture (American Indian sculpture).

Olmsted, Frederick Law (1822-1903), was an American landscape architect, city planner, and writer on social issues. Olmsted's career was shaped by his idea of a civilized society. Through his landscape designs and writings, he tried to recast the form of America's cities and suburbs, and to promote the refinement and culture he thought the citizens of a republic could attain. He criticized the slaveholding South because he believed the region lacked the social and cultural institutions that would raise the level of civilization there.

In 1858, Olmsted and English architect Calvert Vaux submitted a plan for New York City's Central Park, America's first great urban park. Olmsted then supervised its construction and modified its design to give the park its most distinctive features. These include the separation of all forms of traffic and the sweeping natural scenery that would provide New Yorkers with an alternative to the sights and sounds of the city. After 1872, Olmsted and various partners designed Belle Isle Park in Detroit, Mount Royal Park in Montreal, and Roger Williams Park in Providence, Rhode Island. Olmsted planned parksystems for Seattle; Boston; Atlanta, Georgia; New York City; and Louisville, Kentucky.

In addition, Olmsted planned suburban developments, colleges, and the grounds for many institutions and public buildings. His most notable designs include the grounds of the U.S. Capitol in Washington, D.C. (1874), the layout for the World's Columbian Exposition in Chicago (1893), and the New York State Reservation at Niagara (1879). Olmsted also designed such communities as Riverside, Illinois; and Parkside, in Buffalo, New York.

Olmsted was born in Hartford, Connecticut. His son, Frederick Law Olmsted, Jr., was also a well-known landscape architect and city planner.

David Schuyler

Olsom, Charles (1910-1970), was one of the most influential American poets of his time. In 1948, Olson began teaching at Black Mountain College, an experimental school in Black Mountain, North Carolina. He served as the school's rector (head) from 1951 to 1956. At the college, Olson taught Robert Creeley, Robert Duncan, and other young writers who became leading poets.

Charles John Olson was born in Worcester, Massachusetts. His chief work was a long cycle (series of poems) called The Maximus Poems. Publication of this complex work began in 1953 and ended in 1975 after his death. In it, Olson used Gloucester, Massachusetts, symbolically to praise what he admired in human life and to attack the greed and commercialism he saw in American culture.

Olson first gained recognition with Call Me Ishmael (1947), a critical study of the American author Herman Melville. Olson's major poems and critical writings appear in Selected Writings (1966). This collection includes Olson's well-known essay "Projective Verse" (1950), in which he discussed his extremely complicated style of poetry.

Elmer W. Borklund

Olympia, oh LHM peh uh, is a valley about 11 miles (18 kilometers) from Pirgos, Greece. In ancient times, religion, politics, and athletics centered at Olympia. The Olympic Games, held there every four years, were so important in Greek life that they were used as the basis for the calendar. All the buildings in Olympia were for worship or for games. The religious buildings were clustered in the Altis (sacred grove), which lies where the Cladeus River flows into the Alfios River. They included the temples of Zeus and Hera, the Pelopion, the Philippeion, and the great altars.

The athletic buildings lay just outside the Altis. They included a gymnasium; the palaestra, a wrestling and boxing school; the stadium; and the hippodrome, where chariot and horse races were held.

The Olympic Games were banned in A.D. 393, and a fort was built in the Altis. Later, earthquakes and floods covered Olympia under 20 feet (6 meters) of earth.

In 1829, a French expedition began excavations at the temple of Zeus. The German government continued this work. Between 1875 and 1879 the entire Altis and many of the surrounding buildings were uncovered. Fragments of sculpture, coins, terra cotta, and bronze have been found. The major discoveries were two statues, the Victory of Paeonius (423 B.C.) and the Hermes of Praxiteles. The originals of all discoveries remained in
possession of Greece. The Germans reserved the right to take casts from sculptures, coins, or other discoveries. A museum with Olympic relics is at the modern town of Olympia at the edge of the ruins. The modern town provides hotels and other services to the many tourists who visit the ruins. John J. Baxevanis

See also Olympic Games. 

Olympia, oh LHHM pee uh (pop. 42,514; met area pop. 207,355), is the capital of the state of Washington, and the gateway to southwestern Washington and the Olympic Peninsula. An important commercial port, the city lies on the southern inlets of Puget Sound (see Washington [political map]). Oceangoing ships use Olympia’s harbor to export logs, lumber, and other goods. Beds of the Olympic oyster lie in shallow waters near Olympia. Major industries include brewing, food processing, and the manufacture of metal and lumber products. Many Olympians work for the state government. The state capitol, called the Legislative Building, sits on a forested bluff. Its 287-foot (87-meter) dome towers over the area.

Fort Lewis, one of the nation’s largest U.S. Army posts, lies between Olympia and Tacoma. Schools in the area include Evergreen State and St. Martin’s colleges.

Homesteaders began to settle in the area in the 1840s. Edmund Sylvester pioneered in the development of the townsite. Olympia became the territorial capital when the Washington Territory was created in 1853. The city was incorporated in 1859. Olympia has been the state capital since Washington became a state in 1889. In February 2001, a powerful earthquake struck western Washington. Olympia suffered much property damage.

Olympia is the seat of Thurston County. A city manager heads the local government. Mindy Chambers

Olympiad, oh LHHM puh ad. In the Greek system of telling time, an Olympiad was the period of four years that elapsed between two successive celebrations of the Olympic, or Olympic, Games. This way of figuring time became common about 300 B.C. All events were dated from 776 B.C., the start of the first known Olympiad.

The beginning of the year of the Olympiad was determined by the first full moon after the summer solstice, the longest day of the year. This full moon fell about the first of July. Therefore, only the last six months of the first year of the 195th Olympiad corresponded to the first year of Our Lord. This method of counting time ceased about A.D. 440, after the 304th Olympiad. The Olympiads were used as measures of time by later Greek historians and other writers to refer to preceding centuries, but they were never in everyday use, as were months and years. James Jespersen

Olympians. See Mythology (Greek mythology). 

Olympias, oh LHHM puh uhs (375?-316 B.C.), was the wife of Philip II of Macedonia and the mother of Alexander the Great. A proud and emotional woman, Olympias influenced Alexander greatly. She told Alexander that his real father was the god Zeus-Ammon, not Philip. Olympias feared that Philip might choose another heir. Many people believe she had Philip killed to ensure that Alexander would become king. After Alexander’s death in 323 B.C., Olympias tried to keep the empire for her grandson, Alexander IV. She failed, and in 316 B.C. was captured by Cassander, a Macedonian prince. Olympias was eventually killed. See also Alexander the Great (His youth); Philip II. Judith P. Hallott

---

Olympic Games

Olympic Games are the most important international athletic competition in the world. The Olympics bring together thousands of the world’s finest athletes to compete against one another in a variety of individual and team sports. Millions of people have attended the games, and more than 1 billion people throughout the world watch the Olympics on television.

The Olympic Games originated in ancient Greece and were held from 776 B.C. to A.D. 393. The modern games began in 1896. The organizers revived the games to encourage world peace and friendship and to promote healthy sporting competition for the youth of the world.

The Olympic Games consist of the Summer Games and the Winter Games. From 1896 to 1992, the Olympics were held every four years, except in 1916 during World War I, and in 1940 and 1944 during World War II. The Winter Games, which were established in 1924, took place the same year as the Summer Games. Beginning in 1994, the Winter and Summer Games were divided and scheduled on four-year cycles two years apart. For the years and locations of the games, see the table Sites of the Olympic Games in this article.

Olympic ceremonies and symbols

Colorful ceremonies combine with thrilling athletic competition to create the special feeling of excitement in the Olympics. The opening ceremony is particularly impressive. The Olympic athletes of Greece march into the stadium first, in honor of the original games held in ancient Greece. The athletes of the other countries fol-

The opening ceremonies of the Olympic Games feature the entry of the athletes into the stadium. Athletes from Greece enter first, followed by teams from the other countries.

The Olympic symbol consists of five interlocking rings that represent Africa, Asia, Australia, Europe, and the Americas. The colors of the rings, from left to right, are blue, yellow, black, green, and red. The flag of every nation competing in the games has at least one of these colors. Under the rings is the Olympic motto, the Latin words Citius, Altius, Fortius. The words are translated as Swifter, Higher, Stronger.

The International Olympic Committee

The International Olympic Committee (IOC) is the governing body of the Olympic Games. The IOC has headquarters in Lausanne, Switzerland. The committee approves the sports and events to be included in the games. The IOC also selects the host cities for the Summer Games and Winter Games, seven years in advance. The cities bidding for the games must prove they can provide athletic facilities for the games and housing for the athletes, coaches, officials, and visiting spectators.
The Olympic flame is lit during the opening ceremonies. The fire is ignited in Olympia, Greece, and transported by relay to the site of the games. The flame symbolizes the light of spirit, knowledge, and life, and it is a herald of peace.

The medal ceremony takes place after the finals of each event. The top three finishers receive a medal and a diploma. They stand at attention on a platform while the flags of their countries are raised and a band plays the national anthem of the country of the gold medal winner.

Host cities provide a special housing compound called the Olympic Village for the athletes and coaches. The prospective hosts must also convince the IOC that they can furnish adequate transportation, food service, and cultural activities. Host cities are chosen by a majority vote of the IOC.

Originally, members of the IOC were elected for life. However, according to a rule change in 1995, all members must retire before they reach the age of 81. The members of the IOC are not allowed to accept instructions on voting from any government or other group or individual. New members of the IOC are elected by current members. There are no rules setting the size of the IOC or what countries should be represented.

Olympic competition

Every country or territory competing in the Olympic Games is represented by a national Olympic committee. In the mid-1990s, about 195 nations and territories had such groups. Each committee is responsible for selecting its national team, providing uniforms and equipment, and furnishing transportation to the Olympic site.
Most countries use government funds to pay their Olympic expenses. The IOC also provides financial aid. The United States is the only large nation whose government does not give its team financial support. The U.S. team is largely financed by contributions from private corporations and individuals.

**Selection of the athletes.** In many countries, athletes qualify for the Olympics by winning or finishing high in competitions called *selection trials.* In most cases, athletes are invited to the trials based on their performance in national and international competitions.

An athlete representing a country must be a citizen of that country. For many years, only amateur athletes competed in the games. This gave an advantage to wealthy athletes who could devote all their time to training without worrying about earning money. Professional athletes are now eligible to compete in most Olympic sports. Exceptions include baseball and boxing.

**Entries.** In most Olympic sports, a nation may enter as many as three competitors in each event as long as the athletes meet a minimum standard set by the international governing body of that sport. Team sports are limited to 8 to 16 teams per sport. National teams must win or place high in qualifying tournaments to make the final competition. The host country is allowed to enter a team in every team event.

**Medals.** The top three finishers in each event receive a medal and a diploma. The next five finishers get only a diploma. Each first-place winner receives a gold medal, which is actually made of silver and coated with gold. The second-place medal is made of silver, and the third-place medal is bronze. The design for the medal changes for each Olympics. All members of a winning relay team get a medal, including those who participated only in qualifying rounds. In team sports, all the members of a winning team who have played in at least one of the games during the competition receive a medal.

The top three finishers receive their medals in a ceremony after the event. The medal winners stand at attention on a platform, with the gold medalist in the middle. The silver medalist stands on the gold medalist’s right and the bronze medalist on the left. The flags of their countries are raised, and a band plays the national anthem of the country of the gold medal winner.

Olympic competition is intended to test the skill of individuals and teams, not nations. Therefore, the IOC does not keep an official score among the nations. No country ‘wins’ the Olympics. However, unofficial medal totals are compiled for the press and the public.

**The Summer Games**

The Summer Games are held during the summer season of the host city, usually between July and October, and last 16 days. Athletes compete in more than 270 separate events during the Summer Games. A sport must be played in at least 75 countries on four continents before it can be considered for men’s competition. To be eligible for women’s competition, a sport must be played in 40 countries on three continents.

The Summer Games have grown enormously. In the first modern games in 1896, about 311 male athletes representing 13 nations competed. Today, more than 10,000 male and female athletes representing over 190 nations participate.

**The Winter Games**

The Winter Games are usually held in February and last 16 days. A sport must be played in at least 25 countries on three continents to be considered. The Winter Olympics include over 60 events. The games attract approximately 2,000 athletes from about 60 countries.

**Track and field stars of the 2000 Summer Olympics**

The 2000 Summer Olympics included Haile Gebrselassie of Ethiopia and Marion Jones of the United States. Gebrselassie, wearing number 1638, barely defeated Paul Tergat of Kenya, number 2393, in the men's 10,000-meter run. Jones, number 3337, won the women's 100-meter race, shown here. She also won two other gold medals and two bronze medals, becoming the first female track and field athlete to win five medals in a single Olympic Games.

*Olympic record.*

**Leontien Zijlaard** of the Netherlands won the women's road race, *shown here*, as well as cycling gold medals in the 4,000-meter individual pursuit and road time trial.

**Fu Mingxia** of China won the women's springboard diving gold medal. She also won the event in 1996 as well as the platform diving gold medals in the 1992 and 1996 games.

**Rulon Gardner** of the United States, *right*, defeated defending Olympic champion Alexander Karelin of Russia to win the gold medal in the 130-kilogram class in Greco-Roman wrestling.

**Ham Thorpe** of Australia won three gold medals in swimming. He won the 400-meter freestyle, *shown here*, and swam on Australia's winning 400-meter and 800-meter freestyle relay teams.
The ancient games

Athletics played an important role in the religious festivals of ancient Greece. Historians believe the ancient Greeks first organized athletic games as part of funeral ceremonies for important people. This practice probably existed by the 1200's B.C. Later, games became part of religious festivals honoring the gods. Many Greek cities held festivals every two or four years.

Over time, four great religious festivals developed that brought together people from throughout the Greek world. These festivals were the Isthmian, Ne-meian, Pythian, and Olympic games. The Olympic Games, which ranked as the most important, honored Zeus, the king of the gods.

The first recorded Olympic contest took place in 776 B.C. at Olympia in western Greece. The first winner was Koroibos (also spelled Coroebus), a cook from Elis. The Olympic Games were held every four years. They were so important to the ancient Greeks that time was measured in Olympiads, the four-year intervals between games. The only event in the first 13 games was the stadia, a running race of 192 meters (210 yards). Through the years, longer running races were added.

Other types of competition became part of the ancient Olympics. In 708 B.C., wrestling and the pentathlon were added. The pentathlon was a combination of jumping, running, the discus throw, the javelin throw, and wrestling. Boxing joined the program in 688 B.C., and the four-horse chariot race was added in 680 B.C. Horse racing was included in 646 B.C., as was the pentathlon (also spelled pankration), a combination of boxing, wrestling, and kicking. Some unusual events were included in the Olympics, such as a race in armor, a chariot race called the apene in which two mules pulled the chariot, and a competition for trumpeters.

The ancient Olympics produced several famous champions. Milo of Kroton won the wrestling competition five times between 532 and 516 B.C., and Leonidas of Rhodes won three running races in each of four Olympics from 164 to 152 B.C.

The Romans conquered Greece during the 140's B.C., and the games soon lost their religious meaning. In A.D. 393, Emperor Theodosius I banned the games.

The modern games

The modern games begin. In 1875, a group of German archaeologists began to excavate the ruins of the stadium and temples of Olympia, which had been destroyed by an earthquake and buried by a landslide and floods. Their discoveries inspired Baron Pierre de Coubertin, a French educator, to organize a modern international Olympics. He first proposed the idea publicly in 1892. In 1894, the first IOC was formed.

The first modern Olympic Games were held in Athens, Greece, in 1896. The athletes competed in nine sports: (1) cycling, (2) fencing, (3) gymnastics, (4) lawn tennis, (5) shooting, (6) swimming, (7) track and field, (8) weightlifting, and (9) wrestling. James B. Connolly of the United States became the first modern Olympic champion, winning the triple jump (then known as the hop, step, and jump).

The games of 1900 and 1904 attracted little attention. The 1900 Olympics were held as part of the Universal
Exposition, a world's fair in Paris. Competition was spread out over five months. Attendance was poor, and some athletes did not even realize they had participated in the Olympics. The 1900 Olympics included the first competitions involving women, in lawn tennis and golf. The first women gold medalists were British tennis player Charlotte Cooper and American golfer Margaret Abbott. Poor attendance and other problems also plagued the 1904 Olympics, held as part of the Louisiana Purchase Exposition in St. Louis, Missouri.

In the early years of the Olympics, competitions were held in several sports that were later dropped. They included polo, croquet, tug of war, live pigeon shooting, the high jump on horseback, and a swimming obstacle race.

The Olympic movement might have died except for the Intercalated, or Interim, Games held in Athens in 1906. The IOC did not consider these games official. However, they were popular and held the movement together until the next official games in London in 1908. The most dramatic moment of the 1908 games came in the marathon. Dorando Pietri of Italy entered the stadium in first place but collapsed before reaching the finish line. Officials dragged Pietri across the finish line and declared him the winner, but he was later disqualified because he did not finish under his own power.

The 1912 Olympics in Stockholm, Sweden, were the first well-organized Olympic Games. The hero of Stockholm was Jim Thorpe, an American Indian who easily won the 10-event decathlon and the 5-event pentathlon. Thorpe’s medals were taken away after it was discovered that he had played baseball for a small salary before the games, making him a professional athlete and therefore ineligible for the Olympics. In 1982, the IOC voted to return the medals to Thorpe’s family and put his name back in the record books as an Olympic champion.

Between the wars. The 1916 games were canceled because of World War I (1914-1918). The 1920 Olympics in Antwerp, Belgium, marked the first appearance of the great Finnish distance runner Paavo Nurmi. He competed in all three Olympics of the 1920s, winning nine gold medals.

Figure skating was included in the 1908 games, and both figure skating and ice hockey were part of the 1920 games. The first separate Winter Games took place in Chamonix, France, in 1924, with 281 men and 13 women representing 16 countries.

The 1924 Summer Games were held in Paris. One of the stars was American swimmer Johnny Weissmuller, who later became famous portraying Tarzan in motion pictures. Other famous athletes included British sprinters Harold Abrahams and Eric Liddell, later portrayed in the film Chariots of Fire (1981).

The 1928 Summer Games, held in Amsterdam, the Netherlands, were the first in which women competed in track and field. In the Winter Games in St. Moritz, Switzerland, Sonja Henie of Norway won her first gold medal in women's figure skating. She repeated as champion in the 1932 and 1936 Winter Games before becoming a star of Hollywood musicals.

The 1932 Summer Games were held in Los Angeles. These games introduced automatic timing for races and the photo-finish camera. The first Olympic Village was also erected. The games produced the first U.S. female Olympic star, Babe Didrikson (later Babe Didrikson Zaharias). She qualified for five track and field events but was allowed to enter only three. She won the javelin throw and the hurdles race and finished second in the high jump.

In 1931, the IOC chose Berlin, Germany, as the site for the 1936 Summer Games and Garmisch-Partenkirchen, Germany, for the Winter Games. Two years later, Adolf Hitler and his Nazi Party rose to power in Germany. As Hitler’s policies became known, there were pleas to move the Summer Games, but the IOC refused.

The Berlin games were the first to be preceded by a torch relay of the Olympic flame from Greece, and they were the first games to be shown on television. But the 1936 Summer Olympics are best remembered for Hitler’s failed attempt to use them to prove his theory of racial superiority. The Nazis glorified the Germans and other northern European peoples, while claiming that Jews, blacks, and other groups were inferior. But the most successful athlete in the Summer Games was Jesse Owens, an African American who won four gold medals in track and field. The German spectators, ignoring Hitler’s speeches against black people, treated Owens as their favorite hero of the games.

The postwar games. The Olympics scheduled for 1940 and 1944 were canceled because of World War II (1939-1945). The first postwar Summer Games were held in London in 1948 and the Winter Games again in St. Moritz. The most popular athlete in the Summer Games was Fanny Blankers-Koen of the Netherlands, a home-
maker who won four gold medals in track and field. A star of the Winter Games was Dick Button of the United States, who won the gold medal in figure skating, an achievement he repeated in the 1952 games. Barbara Ann Scott of Canada won the women’s figure-skating title, becoming the first Canadian figure skater to win an Olympic gold medal.

Athletes from the Soviet Union made their first Olympic appearance in the 1952 Summer Games in Helsinki, Finland. By the 1956 games, Soviet athletes were winning more medals than the athletes of any other country. In Helsinki, Emil Zatopek of Czechoslovakia became the only runner to win the 5,000 meters, 10,000 meters, and marathon races in the same Olympics.

The 1956 Summer Games were held in Melbourne, Australia, the first to be held in the Southern Hemisphere. Because of Australian quarantine laws concerning horses, the equestrian events were staged separately in Stockholm. In the weeks preceding the Melbourne games, Israel invaded Egypt and Soviet troops invaded Hungary. These actions led to the first boycotts of the modern Olympics. Egypt, Iraq, and Lebanon withdrew to protest the Israeli take-over of the Suez Canal. The Netherlands and Spain boycotted to protest the Soviet invasion.

The 1960 Winter Games at Squaw Valley in California and the Summer Games in Rome were the first to be televised to the United States. The track and field stars of the Summer Games included American sprinter Wilma Rudolph and marathon winner Abebe Bikila of Ethiopia, the first black African to win a gold medal. American boxer Cassius Clay won the light heavyweight gold medal. He later gained international fame as professional boxer Muhammad Ali.

In 1964, the Summer Games were held in Tokyo, the first Asian city to serve as host. Ukrainian gymnast Larisa Latynina won six medals. In her career, she won a record 18 Olympic medals. The Tokyo games were the last Summer Games for more than 20 years to be free of major controversy.

The 1968 games. The 1968 Summer Games were held in Mexico City during a period of political turmoil throughout the world. The most controversial episode took place during the medal ceremony for the men’s 200-meter dash. The gold and bronze medals were won by African American sprinters Tommie Smith and John Carlos. To protest racism in the United States, both athletes bowed their heads and raised clenched fists during the playing of the U.S. national anthem. At the insistence of the IOC, the U.S. Olympic Committee suspended both men from the Olympic team and ordered them to leave the Olympic Village.

Mexico City’s high altitude was disastrous for athletes in long-distance races and other endurance events, but it contributed to world records in many other contests. The most famous record was 29 feet 2 ½ inches (8.90 meters) in the long jump, set by Bob Beamon of the United States. The jump became a new world record that lasted for 23 years.

The 1968 Winter Games in Grenoble, France, produced one of the great Olympic heroes of the 1960’s. French skier Jean-Claude Killy won three gold medals and became an international celebrity.

Terrorism in Munich. The 1972 Summer Games were held in Munich, in what was then West Germany. The Munich Olympics are remembered for the events of September 5. Eight Palestinian terrorists broke into the Olympic Village and entered the dormitory where the Israeli team was staying. They killed two Israelis and took nine hostages. They demanded that Israeli authorities release more than 200 Arab prisoners being held in Israel. During a battle with West German sharpsho-
ers, all the Israeli hostages were killed, along with five terrorists and one policeman.

The highlight of the competition was swimmer Mark Spitz of the United States, who won seven gold medals. The Soviet Union also won a controversial victory over the U.S. men's basketball team in the championship game. The Americans led by 1 point when the buzzer sounded to end the game. But the officials twice ordered the game to continue, first for 1 second and then for 3 seconds more, enabling the Soviet team to score the winning basket.

**Boycotts.** The 1976 Summer Games, held in Montreal, Canada, were hit by a boycott led by Tanzania. More than 20 African nations and 2 other countries refused to compete. The boycotters demanded that New Zealand be banned from competition because a New Zealand rugby team had toured South Africa. At that time, South Africa had a white-controlled government that enforced a policy of rigid racial segregation called *apartheid.* South Africa was barred from the Olympics because of its racial policies, but the IOC said it had little control over the travel of rugby teams because rugby was not an Olympic sport.

In spite of the absence of hundreds of top athletes, the 1976 games were filled with outstanding performances. A 14-year-old gymnast from Romania named Nadia Comaneci caused a sensation by earning the first perfect score of 10 ever awarded in the Olympics. She eventually earned seven scores of 10 and won three gold medals.

The 1980 Summer Games in Moscow were disrupted by another boycott, this one led by U.S. President Jimmy Carter. The boycott protested the Soviet Union's 1979 invasion of Afghanistan. Carter urged other nations to join the boycott, and about 55 nations stayed away as part of the protest.

The 1980 Winter Games in Lake Placid, New York, were among the most exciting in history. Eric Heiden won all five speed-skating races, setting an Olympic or world record in each race. He became the first athlete to win five individual gold medals in one Olympics. Mark Spitz had won three of his seven gold medals as a member of a winning relay team.

Also at the 1980 Winter Games, the United States ice hockey team won an unexpected gold medal. The American team upset the Soviet Union team in an emotional semifinal match and then defeated Finland in the finals.

The games returned to Los Angeles in 1984. With the games being held in the United States, the Soviet Union launched a revenge boycott. Only 13 countries joined the boycott, but they included such sports powers as Bulgaria, East Germany, Cuba, and Hungary. Among the sports that lost most of their medal favorites were weightlifting, wrestling, gymnastics, women's swimming, and women's track and field. However, China competed in the Olympics for the first time in more than 30 years. China was led by the popular gymnast Li Ning, who won six medals. United States track and field star Carl Lewis matched Jesse Owens's 1936 feat of winning four gold medals.

**Charges of steroid use.** The 1988 Summer Games were held in Seoul, South Korea, and were boycotted by North Korea and Cuba. Instead of political controversy, disputes over the use of drugs called *anabolic steroids* marked the 1988 games. Anabolic steroids are artificial forms of male hormones used to increase strength and weight. Their use is banned in Olympic competition. Since 1968, the IOC has tested athletes for steroids and other performance-enhancing drugs.

In the 1988 Olympics, Ben Johnson of Canada defeated Carl Lewis in the 100-meter dash and set a world record. Three days later, the IOC announced that Johnson had tested positive for steroids and was disqualified. Lewis was awarded the gold medal, thus becoming the first man to win the 100-meter dash twice. He also won the long jump for the second time. Other notable performers were swimmers Matt Biondi of the United States, who won five gold medals, and Kristin Otto of East Germany, who won six.

In the 1988 Winter Games in Calgary, Canada, Katarina Witt of East Germany won the women's figure-skating title. Witt also had won the event in 1984. She was the first woman to repeat as champion since Sonja Henie.

**The recent games.** The 1992 Summer Games in Barcelona, Spain, reflected the breakup of the Soviet Union and the collapse of Communist governments in Eastern Europe. Germany entered a unified team representing the former countries of East and West Germany. The Baltic states of Estonia, Latvia, and Lithuania, previously part of the Soviet Union, competed as separate nations. Russia and other former Soviet republics competed as the Unified Team. However, when athletes from the Unified Team won a medal, they were honored by the raising of the flag of their own republic and by the playing of their own national anthem. South Africa, which had ended apartheid, rejoined the Olympics and competed for the first time since 1960.

The 1992 Olympics also marked the first time that professional basketball players were eligible for the competition. This rule change led to the creation of a U.S. "Dream Team" that included Magic Johnson, Larry Bird,
Michael Jordan, Charles Barkley, and other stars of the National Basketball Association. The American team easily won the gold medal.

Speed-skater Bonnie Blair was a star of the Winter Games of 1988, 1992, and 1994. She won five gold medals and a bronze medal in the three games.

The 1996 Summer Games were held in Atlanta, Georgia. Stars included Russian gymnast Alexei Nemov, who won six medals; South African swimmer Penny Heyns, who set two Olympic records; and Michael Johnson of the United States, the first male track athlete to win the 200-meter and 400-meter races in the same Olympics. The 2000 Summer Games in Sydney, Australia, were the largest in Olympic history, with athletes competing for medals in 300 events. Drug problems continued to cast a cloud over the games. Several athletes were disqualified for taking illegal drugs. Some forfeited medals after failing drug tests. Stars of the games included Marion Jones of the United States in track and field, Australian swimmer Ian Thorpe, Chinese diver Fu Mingxia, and cyclist Leontien Zijlaard of the Netherlands.

A controversy arose in the 2002 Winter Games over the judging of the figure skating pairs competition. Judges first awarded the gold medal to Elena Berezhnaya and Anton Sikharulidze of Russia and the silver medal to Jamie Sale and David Pelletier of Canada. After a protest and investigation, the Canadians were awarded a gold medal along with the Russians.

David Wallechinsky

Related articles. World Book has separate articles on many Olympic sports, including gymnastics, ice skating, swimming, and track and field. See also the following:

Outline
I. Olympic ceremonies and symbols
II. The International Olympic Committee
III. Olympic competition
   A. Selection of the athletes

Great moments in Olympic competition occurred in the 1976 and 1980 games. In the 1976 Summer Games, Nadia Comaneci of Romania, shown here, became the first gymnast in Olympic history to score a perfect 10. In the 1980 Winter Games, the United States ice hockey team upset the Soviet team in the semifinals, shown here, and then defeated Finland to win the gold medal.
The "Dream Team" was the name given to the American men's basketball team that won the gold medal at the 1992 Summer Games. The stars of the team came from the National Basketball Association. The 1992 Olympics marked the first time professional players could participate. American professional teams also won in 1996 and 2000.

Questions
What are the five colors of the Olympic symbol? Why did the United States boycott the 1980 Summer Olympic Games? Who was the first U.S. female Olympic star? How many days do the Summer and Winter Olympic Games last? When did the ancient games begin? When did the modern games begin? Who was the first Canadian figure skater to win a gold medal in the Winter Games? How many finishers receive a medal in an Olympic event? Who was Baron Pierre de Coubertin? What "first" did Nadia Comaneci achieve in the 1976 Summer Games?

Wallechinsky, David. The Complete Book of the Summer Olympics. The Complete Book of the Winter Olympics. Over-

Cathy Freeman of Australia won the women's 400-meter race. Freeman gained international publicity during the competition because of her Aboriginal heritage.

Olympic National Park, oh LIHM pihk, lies in the Olympic Peninsula of Washington, not far from Seattle and Tacoma. The jagged peaks of the Olympic Range cover much of the national park. For the area of Olympic National Park, see National Park System (table: National parks). The park has campgrounds and winter sports activities for tourists. Olympic National Park headquarters are at Port Angeles, Washington, a resort city on the Strait of Juan de Fuca.
Of special interest are the rain forests consisting mainly of Sitka spruce, western hemlock, western red-cedar, and Douglas-fir. These rain forests, resulting from good soil and exceptionally heavy rainfall, are almost tropical in luxuriance, with an undergrowth of vine maple, bigleaf maple, ferns, and other junglelike growth. Mosses drape the branches and tree trunks. The park is the home of the world's largest herd of Roosevelt elk, estimated at 5,000 animals. Other wildlife species include black bear, cougar, and black-tailed deer.

This wilderness of glacier-clad peaks, flower-strewed alpine meadows, turbulent streams and jewellike lakes, and deep valleys supporting a rich forest growth is often described as America's "last frontier." Highways penetrate only its outer fringes, but the park has several hundred miles of hiking and horseback riding trails. Nearly 1,000 varieties of flowers grow in the park's meadows and on its mountain slopes. Some varieties, such as the Piper bellflower, grow nowhere else.

Part of this region was set aside as Mount Olympus National Monument by President Theodore Roosevelt in 1909. In 1938, President Franklin D. Roosevelt signed the act establishing Olympic National Park. The park was formally dedicated in 1946. The Queets Corridor and Olympic Ocean Strip were added to the park by presidential proclamation in 1953.

Criticaly reviewed by the National Park Service

Omaha, OH muh HAH or OH muh HAH (pop. 390,007; met. area pop. 716,998), is the largest city in Nebraska. It ranks as one of the world's leading food processing centers. The city also serves as the trading center for eastern Nebraska and western Iowa. For the location of Omaha, see Nebraska (political map).

Omaha took its name from the Omaha Indians. In 1834, this tribe gave most of its hunting grounds in the eastern Nebraska area to the United States government. That same year, the Council Bluffs and Nebraska Ferry Company, a land development firm, founded the town of Omaha City. The name of the town was later shortened to Omaha. The company chose the site for settlement because of its location on a bluff at a ferry crossing at the start of the Mormon Trail.

The city covers 102 square miles (264 square kilometers) on the west bank of the Missouri River. The city of Council Bluffs, Iowa, lies across the river and makes up part of the Omaha metropolitan area. This area covers 2,476 square miles (6,413 square kilometers) and consists of Cass, Douglas, Sarpy, and Washington counties in Nebraska and Pottawattamie County in Iowa.

Omaha's main business district lies near the Missouri River. In the heart of the downtown area stands the city's tallest building, the 45-story First National Center.

Whites make up about 78 percent of Omaha's population. About 13 percent of the people are African Americans. Hispanics of any race make up about 8 percent. The city also has a small number of Asians and American Indians.

Economy. Omaha has about 550 manufacturing plants. Food processing ranks as the city's most important industry. Omaha is one of the chief frozen food producers in the United States.

Other major Omaha industries include machinery manufacturing, metalworking, printing, publishing, and the manufacture of telephone and electric equipment. The city is a national center for telemarketing companies, which promote and sell products by telephone. Omaha is also an insurance center. About 35 insurance firms have their home offices in the city, including Mutual of Omaha, one of the largest insurance companies in the United States.

Railroads provide freight service to Omaha, and passenger trains also serve the city. Airlines use Epplle Airfield. Bus lines and trucking firms also operate in Omaha. Barge lines help make the city an important Missouri River port. Omaha has one daily newspaper, the Omaha World-Herald.

Education. Omaha is the home of the Nebraska School for the Deaf. Girls and Boys Town, a famous community for homeless and underprivileged children, is just west of Omaha (see Girls and Boys Town).

Colleges and universities include the University of Nebraska at Omaha, Creighton University, the University of Nebraska Medical Center, the College of St. Mary, and Grace College of the Bible. The campuses of the Metropolitan Technical Community College are also in Omaha.

Cultural life and recreation. The Joslyn Art Museum features works from ancient to modern times, with a special emphasis on European and American art of the 1800s and 1900s. The museum is noted for its collection of art of the American West. Other museums include the Omaha Children's Museum and the Durham Western Heritage Museum, a history museum in a restored railroad station. The city has a symphony orchestra. The Omaha Community Playhouse, which first opened in 1925, presents plays in two theaters.

Omaha has more than 120 parks, which cover a total of about 5,000 acres (2,000 hectares). The Henry Doorly Zoo, in the southeastern part of the city, attracts many visitors. The zoo's Lied Jungle is an indoor re-creation of rain forests of Asia, Africa, and South America. Lauritzen Gardens, Omaha's Botanical Center, is just north of the zoo. Fontenelle Forest, the largest unbroken tract of forestland in Nebraska, lies south of Omaha.

Every June, top college baseball teams come to Omaha to compete in the National Collegiate Athletic Association College World Series. The Knights of Ak-Sar-Ben, a civic organization with more than 25,000 members, sponsors a rodeo and livestock show every September. This organization, whose name is Nebraska spelled backwards, was founded in 1895.

Government. Omaha has a mayor-council form of government. The voters elect the mayor and the seven council members to four-year terms. Omaha gets most of its income from a property tax and a city sales tax.

History. Many Indian tribes, including the Omaha and the Oto, once hunted buffalo in what is now the Omaha area. The famous expedition headed by Meriwether Lewis and William Clark passed through the area in 1804 on its way to the West.

In 1854, a treaty between the United States government and the Omaha Indians opened the newly created Nebraska Territory for settlement. The Council Bluffs and Nebraska Ferry Company surveyed and laid out the site of Omaha. The firm sold land for $25 per lot. In 1855, the first territorial legislature selected Omaha as the
capital, Omaha was incorporated as a city in 1857.

In the late 1850s, Omaha became an outfitting point for wagon trains headed for the newly discovered gold fields of Colorado. But the city grew slowly and, in 1860, had a population of only 1,183.

Many Nebraskans had opposed the selection of Omaha as the territorial capital. Many more of the territory's people lived south of the Platte River. They felt that the capital should not be north of the Platte, as Omaha is. After Nebraska became a state in 1867, the city of Lincoln was chosen as the new capital. The state government moved to Lincoln, 50 miles (80 kilometers) southwest of Omaha, in 1868.

In 1863, President Abraham Lincoln had selected the Council Bluffs area as the starting point of the Union Pacific Railroad. In 1865, the first tracks were laid westward from Omaha. The Union Pacific thus became part of the first U.S. transcontinental railroad system, which was completed in 1869. Omaha began to grow rapidly and had 16,083 people by 1870.

During the 1880s, Omaha developed into an important meat-processing center. The city's location in a great cattle-raising area and at the heart of a rail network helped this growth. The opening of the Union Stockyards in 1884 hastened the growth. Thousands of immigrants, many from southern and central Europe, worked in Omaha's meat-packing plants.

In 1898, the Knights of Ak-Sar-Ben organized the Trans-Mississippi and International Exposition, which attracted more than 2.5 million visitors to Omaha. By 1900, the city had 102,555 people. The population reached 191,601 in 1920, and 223,844 in 1940. The number of factories grew from 150 in 1900 to 450 in 1950. In 1948, the U.S. Air Force established the headquarters of the Strategic Air Command (SAC) at Offutt Air Force Base, near Omaha. SAC was eliminated in 1992 during a reorganization of the Air Force. The base is now the headquarters of the U.S. Strategic Command.

Changes in the city during the last half of the 1900s included turning a wholesale fruit and vegetable market south of the downtown area into a visitor attraction called Old Market. Old Market is a brick-paved district with shops, art galleries, and restaurants. Other projects included the construction of a hotel and several large office buildings in downtown Omaha. The Central Park Mall also was completed. The mall links the city's business district to the riverfront.

In 2001, construction began on a new convention center and arena on the northeast edge of the downtown area. Completion was scheduled for 2003.

Lawrence H. Larsen

For the monthly weather in Omaha, see Nebraska (Climate). See also Nebraska (pictures).

Oman Indians live mainly in northeast Nebraska. Many make their homes on a reservation there. Many others live in Lincoln or Omaha or in Sioux City, Iowa. The city of Omaha was named after the Omaha Indians.

The Omaha once lived in the Ohio River Valley along with ancestors of the Kansa, Osage, Ponca, and Quapaw Indians. They all spoke similar Siouan languages. Eventually, the groups separated, and most of them moved west. The Omaha arrived in Nebraska about 1700. Many Omaha still speak their own language.

In Nebraska, the Omaha traditionally lived in earth lodges in villages near the Missouri River. An Omaha earth lodge consisted of a circular log frame covered with layers of branches, grass, and earth. The Omaha planted corn and other crops in the spring. In summer, they moved west to hunt buffalo and lived in tepees. In the fall, they returned to the village with supplies of dried buffalo meat and harvested their corn. They hunted deer in the winter. John Ludwicksson

Oman, oh MAHN, is a small country on the southeastern end of the Arabian Peninsula. Most of the land is desert, but it holds large deposits of petroleum. Muscat is Oman's capital and largest city.

Oman lies on the Gulf of Oman and the Arabian Sea. The country is bordered by Yemen on the southwest and Saudi Arabia on the west. The northern tip of Oman, the Musandam Peninsula, is separated from the rest of the country by the United Arab Emirates. The peninsula lies on the strategic Strait of Hormuz. This narrow waterway separates the Persian Gulf from the Indian Ocean, which opens to the east of the Gulf of Oman. All oil exported by ship from the Persian Gulf must pass through the strait.

Oman was extremely poor until oil was discovered there in 1964. The government has used oil revenues to finance economic improvements, and the standard of living of the population has risen. Nevertheless, most Omanis still struggle to earn a living.

Government. Oman is ruled by a monarch called the sultan. The sultan appoints cabinet members who oversee the operations of the government. Two councils advise the sultan. The sultan appoints the 41 members of the Council of State. He chooses the 82 members of the Consultative Council from among candidates elected by voters in each of Oman's 59 wilayats (districts). Oman has a Chief Court and local courts. All judges are experts in Islamic law.

People. Most of the population is Arab, and these people belong to various tribal and religious groups.
Oman

Facts in brief

Capital: Muscat.

Official language: Arabic.

Official name: Sultanat Uman (Sultanate of Oman).

Area: 82,030 mi² (212,457 km²). Greatest distances—north-south, 500 mi (805 km); east-west, 400 mi (644 km). Coastline—about 1,060 mi (1,700 km).

Elevation: Highest—Jabal Ash Sham, 9,957 ft (3,035 m) above sea level. Lowest—sea level.

Population: Estimated 2002 population—2,711,000; density, 33 per mi² (13 per km²); distribution, 72 percent urban, 28 percent rural. 1993 census—2,018,074.

National anthem: 'Nashid as-Salaam as-Sultani' ("Sultan’s National Anthem").

Flag: The flag has a vertical red stripe and three horizontal stripes of white, red, and green. The national emblem, which features crossed swords and a dagger, appears at the top of the vertical stripe. See Flag (picture: Flags of Asia and the Pacific).

Money: Basic unit—Omani rial, or riyal. One thousand baizas equal one rial. See also Rial.

The largest of the many non-Arab minorities who live in Oman are Baluchis—that is, people from the Arabian Sea coast of Iran and Pakistan—and Asian Indians. The country’s official language is Arabic.

Most rural Omanis live in villages. Most people who live in coastal villages work on date palm plantations. Some fish for a living. Farmers in the interior villages grow dates, fruits, and grain. Some also raise animals.

Old Omani houses in coastal villages are made of palm leaves to allow the sea breezes to cool them. Old houses in villages in the interior are built of mud brick and stone. Newer housing is constructed from cement blocks. Some major towns have large stone fortresses that were built hundreds of years ago and beautifully decorated palaces where prominent families once lived.

Nomads make up about 5 percent of Oman’s population. Nomads move from place to place as they search for water and grazing for their herds of goats, camels, and small cattle. They live in tents.

Omanis depend on wells for water for most or all of the year. Before the Arabs took over Oman, Persians lived there and built canals called aflaj (singular falaj) to carry water to the villages. Many aflaj carry water from underground wells tapped by tunnels called qarnat.

Growing numbers of urban Omanis have jobs in industry, including the petroleum industry. Most city dwellers, however, are government workers, laborers, merchants, or sailors. Their houses are generally built of whitewashed mud brick. These houses are built around a central courtyard, and many have flat roofs surrounded by high walls. Some people sleep on these roofs during hot weather. The larger cities also have modern high-rise buildings.

Most Omanis are Muslims. Many belong to the moderate Ibadi (also spelled Ibadhi) branch of the Kharijite division of Islam. Ibadi Muslims have traditionally believed that the religious leader, the imam, should be elected based on merit. See Islam (Divisions of Islam).

The lives of most Omani women center on their homes and families. They follow Islamic religious rules about modest dress. When Omani women leave their houses, they wrap themselves in long black cloaks called abayas, and some also wear black masks called burqas to cover their faces. These garments also protect them from the sun. Many Omani men wear a long white robe called a dishdasha. They often carry decorative knives called khanjars, which they wear in brightly colored sashes. In rural areas, some men carry rifles.

Since 1970, the government has built many schools for children and has established literacy programs for adults. Because of these efforts, the number of Omani people 15 years old or older who can read and write is rising. Sultan Qaboos University, the first university in Oman, opened in the Muscat region in 1986.

Land and climate. Most of Oman is dry and rocky. The Musandam Peninsula in the north consists of barren mountains. Al Batinah, a narrow coastal plain, lies along the Gulf of Oman. Date palms thrive in this fertile region. Steep, rugged mountains called Al Hajar separate the Batinah from the interior. The interior is a vast, flat wasteland. The Rub al Khali (Empty Quarter), a desert, extends into western Oman from Saudi Arabia. Most of Oman’s coast along the Arabian Sea is barren and rocky. But tropical vegetation grows along the coast in Dhofar.
An Omani craftsman uses a potter’s wheel to make pottery. Like most Omani men, this potter wears loose, white garments and a turban for protection from Oman’s strong sun.

A region in the south, Dhofar is famous for its frankincense trees, the best of which grow on a plateau north of the Jabal al Qara, a mountain range.

Temperatures in Oman may reach 130 °F (54.4 °C) in the summer. Most of Oman receives less than 6 inches (15 centimeters) of rain each year. Dhofar, however, receives up to 25 inches (63.5 centimeters) of rain annually.

Economy. Oil exports provide the major portion of Oman’s national income. However, many Omani work in traditional occupations, such as farming and fishing. Chief crops, some of which are exported, include alfalfa, bananas, coconuts, dates, limes, wheat, and vegetables. Nomads and some settled farmers raise camels, cattle, goats, and sheep. Oman’s fishing fleet catches sardines, sharks, tuna, and other fish and shellfish.

Oman’s chief imports include manufactured goods and equipment needed for its industries. The nation’s main trading partners are Japan, the United Arab Emirates, and the United Kingdom.

History. Human beings have lived in Oman for more than 5,000 years. Beginning in ancient times, Oman’s wooden sailing ships carried goods throughout the Persian Gulf and to coastal areas in south Asia and east Africa. In the 1500s, Portuguese military forces built forts in Muscat and other Omani seaports as well as elsewhere in the Persian Gulf to control this rich trade. The Omani navy and tribal fighters, under the leadership of Sultan bin Saif al-Yaribi, forced the Portuguese from Oman in 1650. The Omanis then attacked rival shipping on the high seas and established control over trading ports along much of the east coast of Africa.

For centuries after the arrival of Islam in Oman during the 600s, members of the Ibadi branch of the faith had come into repeated conflict with the dynasties and foreign powers ruling Oman. In the 1740s, Ahmad bin Said, the first ruler of the Al Bu Said family, united the OMANIS and took power. Ahmad died in 1783. Oman was then increasingly divided between the hereditary Al Bu Said rulers, whose power was based in coastal Muscat, and the more traditional Ibadi tribes of the country’s interior, who looked to elected imams for leadership.

In 1798, the sultan signed the first of several treaties with the United Kingdom. The British competed against Oman for trade dominance in the Indian Ocean. Gradually, Oman’s sea trade declined and its economy suffered. Oman also lost control of its outposts in the east.

Oman was reunited in 1955 by Sultan Said bin Taimur. With British help, the sultan defeated rebellious Ibadi tribesmen of interior Oman in 1959. In the early 1960s, another rebellion against Said began in Dhofar. In 1970, Said’s son Qaboos bin Said overthrew him. Qaboos put down the Dhofar rebellion in the mid-1970s.

Said had been opposing to making Oman a modern state. Qaboos, however, immediately started to modernize the country. He developed the oil industry. He also constructed new irrigation systems and made many other agricultural improvements. He built roads, schools, and hospitals. Before Qaboos became sultan, few Omani children—and hardly any girls—even went to school. Qaboos has encouraged Omanis to educate their daughters as well as their sons.

In 1981, Oman and five other Arab states bordering the Persian Gulf formed the Gulf Cooperation Council (GCC). GCC members work together on military defense and economic projects. Following Iraq’s invasion of Kuwait in 1990, Omani military forces, as part of the GCC and the allied coalition, took part in the 1991 ground campaign that liberated Kuwait.

See also Gulf Cooperation Council; Muscat.

Omar. See Muhammad (His religious life).

Omar Khayyam, OH mahr ky YAHM (1048–1131), was a Persian poet, astronomer, and mathematician. He was famous during his lifetime for his reform of the Islamic calendar. About 100 years after his death, collections of poems appeared bearing his name. These poems express religious skepticism and a rather world-weary hedonism (love of pleasure). The verses show a mind acutely conscious of human ignorance and of the brev-
ity of life. A collection called the Rubaiyat of Omar Khayyam, The Astronomer-Poet of Persia first attracted attention in the West in 1859, when English writer Edward Fitzgerald published his free translation of a number of the stanzas arranged as a continuous poem.

Omar Khayyam was born on May 18, 1048, in Nishapur, in what is now northeastern Iran. His name, which probably reflects an ancestor’s trade, means the tent-maker.  Dick Davis

See also Rubaiyat; Fitzgerald, Edward.

Ombudsman, AHN buhdz MAHN, is a nonpartisan public official who investigates people’s complaints about government officials or agencies. Most of an ombudsman’s work involves complaints of unjust or harsh treatment of people by police, prosecuting attorneys, or judges, and such matters as housing, taxation, voting, or welfare payments. After investigating a complaint, the ombudsman may dismiss it or may seek correction of the problem—by persuasion, by publicity, or, occasionally, by recommending prosecution.

The idea of the ombudsman originated in Sweden in 1809 and spread to other countries. Today in the United States, Hawaii has a comprehensive ombudsman plan, and other states and some cities have modified plans. The idea also has gained popularity in large organizations, including corporations and universities. The ombudsman’s growing popularity coincides with the increasing complexities of administration and with people’s need for impartial and informal handling of complaints.

David R. Berman

Omdurman, AHN dur MAHN (pop. 526,827), is the largest city in Sudan. It lies on the west bank of the Nile River, across the river from Khartoum, Sudan’s capital.

For location, see Sudan (map).

Omdurman is a regional market. It is also a religious and cultural center for Sudanese Muslims. The tomb of Muhammad Ahmed, a Muslim leader called the Mahdi (divinely appointed guide), stands in the city center. Muhammad Ahmed founded the city in 1885. Near the tomb is a large market area called the suq. Many people who work in Khartoum live in Omdurman. Omdurman has modern apartment buildings and houses. It also has small houses made of sun-dried mud-brick. Tents and shacks on the outskirts of the city provide shelter for many refugees from western and southern Sudan and nearby countries.

Kenneth J. Perkins

Omen is supposedly a sign of future good or bad luck. A good omen foretells a desirable event, and a bad omen forecasts disaster. For example, a person may regard a dream about gold as an omen of success in business. Or the person may believe that the death of a relative will follow a dream about losing a tooth. Sometimes omens come from a deliberate attempt to look into the future, such as a fortuneteller’s “reading” cards.

Many ancient societies believed that lightning, thunder, or the behavior of animals foretold events. For example, the Mesopotamians thought fire would destroy the king’s palace if a dog were seen lying on the throne. In Greece, the cry of a hawk warned of danger. Many leaders, when trying to decide on a course of action, asked the gods for a sign. In folklore, many heroes die after disregarding such signs.

Alan Dundes

Omnibus bill, AHN nuh buhs, is a term which is sometimes used for a bill that includes several unrelated measures when it is put before a legislative assembly. It is used to pass several bills at once. It is named for an omnibus (bus), a vehicle that carries a number of people.

Omnibus bills are considered bad practice. When a number of unrelated items are crowded into one bill, it is hard to give each the study it deserves. In addition, an omnibus bill may include provisions that would be unlikely to pass on their own merits. Sometimes, legislators attach an amendment called a rider to an important bill. Opponents are forced to accept the rider if they want the rest of the bill to become law. The constitutions of most states and provinces provide that a single bill shall relate to one topic only.

Douglas Greenberg

Omsk, ahmsk (pop. 1,157,600), is a major manufacturing center of Russia. It lies along the Irtysh River, about 1,360 miles (2,190 kilometers) east of Moscow, in Siberia (see Russia [political map]). Omsk is one of the largest cities in Siberia.

Omsk manufactures farm machinery for the surrounding agricultural area. The city also has large food-processing, oil-refining, and petrochemical industries.

Omsk was founded in 1716, during the Russian expansion into Siberia. The Trans-Siberian Railroad reached the city in 1894, and Omsk became a commercial center of western Siberia. During World War II (1939-1945), the government moved many factories from combat zones in the western part of Russia to safe areas in Siberia. Omsk developed rapidly as a result, and its industries have continued to expand.

Onager, AHN uhr juhr, is the name of a fast-running animal which is a relative of the donkey. It is the wild ass mentioned in the Bible. The onager travels in herds on the hot, dry plains of west-central Asia. Its color varies from cinnamon-brown in summer to yellow-brown in winter. A yellow patch covers each thigh and a broad black stripe runs along its back. The onager also has a mane and a tuft of hair at the end of its tail. It stands about 4 feet (12 meters) tall at the shoulder.

Steven D. Price

Scientific classification. The onager belongs to the horse family, Equidae. The scientific name for the onager is Equus hemionus.

Onagers resemble donkeys but run as swiftly as horses. This onager stands with her foal.
Onassis, Jacqueline Kennedy (1929-1994), the wife of President John F. Kennedy, was one of the most popular first ladies in United States history. President Kennedy was assassinated in 1963. Five years later, Mrs. Kennedy married Aristotle Onassis, a Greek businessman.

Jacqueline Kennedy Onassis was born in Southampton, New York. Her maiden name was Jacqueline Lee Bouvier. She graduated from George Washington University in 1951. From 1951 to 1953, she worked for the Washington Times-Herald, where she produced a daily column as an inquiring photographer. She asked people human-interest questions, such as whether they had done their Christmas shopping, and wrote up the replies. She took pictures of the people, which accompanied the column.

In 1953, Jacqueline Bouvier married Kennedy, who was then a U.S. senator. The couple had two children who survived infancy: Caroline, born in 1957; and John F., Jr., 1960. A daughter was stillborn in 1956, and a son born prematurely in 1963 lived only two days. Kennedy became president in 1961. As first lady, Jacqueline—who was often called "Jackie"—became known for her elegance in hairstyle, clothing, and other elements of fashion. She also won admiration for her composure and dignity following the assassination of her husband on Nov. 22, 1963.

Jacqueline Kennedy married Onassis in 1968. He died in 1975. From 1975 until her death, Jacqueline worked as an editor for book publishers. See also Kennedy, John Fitzgerald.

Onate, oh NYAH tay, Juan de (1550?-1626?), was a Spanish explorer. He is remembered mainly for colonizing the territory now called New Mexico in 1598. His explorations extended from the Colorado River to the plains of Kansas. Onate served as governor of the territory but quarreled with the settlers and was forced to resign in 1607. He was tried and found guilty of immorality and abuse of power. It was largely due to Onate that the city of Santa Fe was founded in about 1610. Onate was born near Zacatecas, Mexico. Helen Delpar

Oncology, abng KAHL uh jee, is the study of the development, treatment, and prevention of cancer. It includes both research and clinical care. Doctors who specialize in oncology are called oncologists.

In the laboratory, oncologists compare human cancer cells with normal cells to try to understand the cellular mechanisms that control the growth of normal tissues. By understanding these mechanisms, oncologists hope to find ways to correct abnormal tissue growth.

Similarly, oncologists study cancers in animals to learn how the body itself often controls the growth of cancer cells. The scientists study how naturally occurring chemicals called interleukins stimulate an animal's immune system to eliminate cancer cells. Through such research on animals, oncologists hope to develop methods of cancer prevention and treatment for people.

Clinical oncologists diagnose and treat cancer. A diagnosis is made by examining a piece of abnormal tissue under a microscope. This procedure, called a biopsy, determines if the tumor is cancerous. Treatment depends on whether tumors are limited to one site or organ in the body or whether cancer cells have spread. Surgery, radiation, drug therapy, or combinations of these treatments may be used (see Cancer [Cancer treatment]).

O'Neal, Shaquille, sha KEEEL (1972- ), is a star center in the National Basketball Association (NBA). O'Neal stands 7 feet 1 inch (216 centimeters) tall and weighs about 300 pounds (136 kilograms). He is known for his strength and for his powerful slam dunks. O'Neal consistently ranks among the NBA leaders in scoring, shooting percentage, rebounds, and blocked shots. He led the NBA in scoring in the 1994-1995 and 1999-2000 seasons. O'Neal won the league's Most Valuable Player award for the 1999-2000 season.

Shaquille Rashaun O'Neal was born in Newark, New Jersey. O'Neal attended Louisiana State University, leaving in 1992 after his junior year to turn professional. The Orlando Magic selected him as the first player in the 1992 NBA draft. He immediately became a dominant player and was named the league's Rookie of the Year for 1992-1993. In 1996, O'Neal signed as a free agent with the Los Angeles Lakers.

O'Neal has appeared in motion pictures and has recorded as a rap artist. His popularity has made him one of the most sought-after athletes for commercials and product endorsements.

See also Basketball (picture).

O'Neale, Peggy (1796-1879), was a central figure in one of the greatest disputes in the history of Washington, D.C., society. The dispute caused President Andrew Jackson to reorganize his Cabinet.

Margaret O'Neale was born in Washington, D.C., the daughter of an innkeeper. Margaret, known by the nickname Peggy, married John B. Timberlake, a navy purser. She lived at the O'Neale tavern while Timberlake was at sea. Senator John H. Eaton of Tennessee lived there in 1818, and became fond of Peggy. Andrew Jackson, who became a U.S. senator from Tennessee in 1823, met Peggy at the inn. Peggy's husband died in 1828, and she married Senator Eaton on Jan. 1, 1829.

Eaton became secretary of war in 1829. Washington society refused to receive Peggy, because of her father's occupation and because of gossip about her conduct with Eaton. President Jackson stood by her, despite his family's protests. Several Cabinet members resigned, and Eaton resigned his post in 1831. James C. Curtis

Onega, Lake. See Lake Onega.

Oneida Community, oh NYU dah, a cooperative community in Oneida, New York, was founded by John Humphreys Noyes in 1848. Noyes hoped to make the community a utopia (perfect society). Noyes, a preacher, believed in a radical form of Christianity known as Perfectionism. Perfectionism taught that people could abolish sin from their lives and become perfect. Noyes began the community in Putney, but he and his followers were forced to leave because of their beliefs.

The members of the Oneida Community believed
that the best way to achieve perfection was to live communally, sharing the burden of labor as well as all possessions. The community abolished the private family and, in its place, set up a system called complex marriage. In this system, every man was considered to be married to every woman. The community also planned the birth of its babies and raised its children. In 1869, the community began to choose combinations of parents that it believed would produce the best children.

The Oneida Community flourished financially. It became wealthy by manufacturing and selling a type of steel game trap invented by one of its members. The community also earned money by canning and by manufacturing steel chains and silk thread.

In 1879, outside opposition to complex marriage forced the community to give up the practice. In 1881, the community was reorganized as a business corporation based on private ownership of stock. In the 1890's, the manufacture of silverware became the community's main industry. The community and silverware company still exist. But few of the voluntary cooperative features of the original community remain.

**Oneida Indians. See Iroquois Indians.**

**O'Neill, Eugene Gladstone** (1888-1953), is regarded as America's greatest playwright. In 1936, O'Neill received the Nobel Prize for literature. Four of his plays won Pulitzer Prizes—*Beyond the Horizon* in 1920; *Anna Christie* in 1922; *Strange Interlude* in 1928; and *Long Day's Journey into Night* in 1937, after his death.

O'Neill's plays show his fascination with philosophy and religion and his intense self-examination. By incorporating experimental techniques of European theater into his plays, O'Neill is credited with raising the previously narrow and insubstantial American drama into an art form that gained worldwide respect.

**His life.** O'Neill was born on Oct. 16, 1888, in New York City. His father, James O'Neill, was one of America's most popular actors. Between national tours, the family spent the summers in New London, Connecticut. Their home was the setting for two of O'Neill's greatest plays—*Ah, Wilderness!* (1933) and *Long Day's Journey into Night* (written from 1939 to 1941 and first performed in 1956). In New London, O'Neill discovered his mother's addiction to morphine and rebelled against his father's theatrical conservatism. O'Neill was raised a Roman Catholic, but he rejected religion. He married in 1909 but was divorced within three years. By 1912, he had worked as a gold prospector in Honduras and as a seaman and had become a frequent of cheap saloons and flophouses in New York City. That year, he returned to New London and became ill with tuberculosis.

O'Neill's reading while recovering at a sanitarium inspired him to become a playwright. In 1914, he studied drama with George Pierce Baker at Harvard University. In 1916, O'Neill joined the Provincetown Players, an experimental theater group on Cape Cod in Massachusetts. In July, the group presented *Bound East for Cardiff*, the first staging of an O'Neill play.

O'Neill's second marriage, to Agnes Boulton, in 1918 ended in divorce in 1929. Later that year, he married actress Carlotta Monterey. He wrote until the mid-1940's, when a muscular disease resembling Parkinson disease prevented further work. O'Neill died largely forgotten. But in 1956, a revival of *The Iceman Cometh* (written in 1939) and the premiere of *Long Day's Journey into Night* aroused a renewed interest in his plays.

**His plays.** O'Neill's career consisted of two periods of realism divided by a middle period of experimentation. He first wrote one-act plays that utilized his youthful experiences, especially at sea. The best of these plays include four realistic works that trace the changing relationships among seamen of the S.S. *Glencairn* amid the tensions of World War I (1914-1918).

In the early 1920's, O'Neill rejected realism and determined to capture on stage the "force behind" human life. He was influenced by the ideas of the German philosopher Friedrich Nietzsche, the Austrian psychologist Sigmund Freud, the Swiss psychologist Carl Jung, and the Swedish playwright August Strindberg.

In *The Emperor Jones* (1920), an expressionistic play, O'Neill traced the personal and racial past of a black porter who becomes a Caribbean dictator. *The Hairy Ape* (1922) blends realistic and expressionistic elements in the story of an alienated man's attempts to belong in modern society. *Desire Under the Elms* (1924) transplants the Greek myth of Phaedra and Hippolytus and elements of other myths to a New England farm.

In *The Great God Brown* (1926), the characters wear masks that express or hide their inner natures. In the nine-act *Strange Interlude* (1928), characters voice inner thoughts that frequently contradict their public utterances. *Mourning Becomes Electra* (1931) is a trilogy that shifts the Greek tragic trilogy the *Oresteia* to America immediately after the Civil War (1861-1865). The gods and Furies of Greek mythology are replaced by the workings of the subconscious mind.

O'Neill's final period was his best as he returned to realism and the more open acknowledgment of a lifelong impulse to write autobiographical plays. *The Iceman Cometh* immortalizes the realistic "pipe dreams" of the friends from the flophouses and Greenwich Village. The play's characters shield themselves from the bitter truth of failure through their mutually supportive illusions. *A Touch of the Poet*, written from 1935 to 1942 and first staged in 1957, is the only complete drama of a planned 11-play cycle. O'Neill intended the cycle to trace the life of an Irish American family and the spiritual decline of America from the early 1800's. In his greatest play, *Long Day's Journey into Night*, the Tyrone family is clearly based on O'Neill's own family in 1912. *A Moon for the Misbegotten* (written from 1941 to 1943 and first performed in 1957) is a sequel that portrays the last days of O'Neill's alcoholic brother, Jamie.

Garlic, Ramp, Leek

Onion is a vegetable that has a strong odor and flavor. Onions rank as one of the world's most popular foods. They are used chiefly as a seasoning and are eaten raw, cooked, dehydrated, and pickled. When cut, raw onions give off a vapor that causes people's eyes to water.

The onion plant. Most onion plants are biennials (plants that require two years to complete their life cycle). When fully grown, they consist of leaves, a bulb, and roots. The long, slender leaves are hollow cylinders that grow upright. They thicken at the base to form a bulb, the part of the plant that people eat most frequently. Onion bulbs grow partially aboveground. They tend to be globe-shaped, but some are wide and flat and others are slender and upright. A thin papery covering made up of dried outer leaves encloses the bulb.

Onion bulbs may be red, white, or yellow. A cluster of short root fibers grows from the bottom of the bulb. During its second year of growth, an onion plant produces rounded clusters of small, greenish-white, seed-bearing flowers at the tips of its stalks. Most onions are harvested during the first year and thus do not flower.

Onions are classified as short-day onions or long-day onions, depending on the amount of daylight needed to begin bulb formation. Short-day onions require 10 to 11 hours of daylight and grow best in the Southern United States. Long-day onions need 14 to 15 hours and grow best in the northern part of the country. Varieties of short-day onions include Excel, Granex, Texas Early Gran, and yellow Bermuda. Long-day varieties include Abundance, Elite, Epoch, Southport Yellow Globe, and Sweet Spanish. To form a bulb, all onion plants require an average temperature greater than 60 °F (16 °C).

Cultivation. Onion growers plant onion sets (small bulbs), seeds, or seedlings. Seedlings are grown in a greenhouse or in areas that have a warm climate during winter. Seeds are planted at a depth of about a \( \frac{1}{2} \) inch (1.3 centimeters). Sets are pressed into the ground but left uncovered. Onions require rich soil. They also need plenty of water, especially when they are young. When the bulb is ready to be harvested, the plant's leaves become limp and fall over. To avoid decay, growers dry and store harvested bulbs in a cool place.

Onions differ in the strength of their flavor. People use such strong-tasting onions as the Southport Yellow Globe in soups and stews. Mild onions, including the Yellow Bermuda and Sweet Spanish, are often eaten raw in salads or on sandwiches. Onions harvested when their bulbs are immature are called green onions or salad onions and are sold with leaves attached.

Onions probably first grew in central or southwestern Asia. Today, the leading onion-growing countries include China, India, and the United States. In the United States, leading onion-growing states include California, Oregon, and Colorado.

Scientific classification. Some botanists classify the onion in the amaryllis family, Amaryllidaceae. Others place it in the lily family, Liliaceae. The onion is Allium cepa.

Online service is a business that provides access to the Internet, a global computer network, and also offers a wide range of content not available on the Internet. This content includes news, databases and software, games, and electronic publications. Computer users subscribe to online services and pay a fee for use. The services charge additional fees for the use of certain content. Online services also sell advertising space.

Online services provide e-mail (electronic mail) features, including individual customer addresses and software that sends, receives, and stores messages. Subscribers can use bulletin boards to post or read messages on various topics. In chat rooms, individuals can discuss shared interests by exchanging messages instantly. Most services have technical experts available online or by telephone to help subscribers solve problems they encounter in using the service.

Typical subscribers use a software package called a Web browser to call up material on the World Wide Web, a portion of the Internet that provides pictures, sound, and video (see World Wide Web). Most online services enable parents to prevent their children from accessing material the parents believe is inappropriate.
Ontario

Ontario, **ahn TAIR ee OH**, has more people than any other Canadian province. About a third of Canada's people live in Ontario. Service industries provide Ontario with its greatest source of income. Ontario's manufacturing industries produce about as much as those of the nine other provinces combined. Ontario ranks first among the Canadian provinces in farm income and metallic mineral production.

Toronto is the capital of the province, and the Toronto area is Canada's leading manufacturing center. Ottawa, the capital of Canada, lies on the Ottawa River in southeastern Ontario.

Ontario has a larger area than any other Canadian province except Quebec. It is the southernmost province, but it also extends so far north that some of the ground beneath the surface is **permafrost** (permanently frozen ground).

The busy factories, mills, and plants of Ontario have given it the nickname **Manufacturing Heartland of Canada**. Most industries are in the warm southern region, south of Lake Nipissing. About 90 percent of the people live there, on about 12 percent of the land area. The province's richest manufacturing section, called the **Golden Horseshoe**, curves around the western shores of Lake Ontario.

Ontario's major industry is manufacturing automobiles. Most of the province's automobile plants are in the Golden Horseshoe. Almost all the automobiles made in Canada come from there. Hamilton, a city in the Golden Horseshoe, is Canada's greatest iron and steel center. Nearby is Toronto, one of the chief Canadian ports on the Great Lakes. The region's varied products travel from Toronto to many parts of the world by way of the St. Lawrence Seaway.

The mines of Ontario provide about a third of all the non-fuel minerals produced in Canada. Deposits near Greater Sudbury yield about one-eighth of the world's supply of nickel. One of the major known uranium deposits in the world lies near Elliot Lake. Ontario is also one of North America's leading producers of gold.

---

The contributors of this article are Walter G. Kemball, President of W. Kemball Curriculum Consultants Inc.; and John T. Saywell, University Professor and Professor of History and Social Science at York University.
Ontario is Canada’s leading producer of eggs and poultry and also leads in the production of fruits and vegetables. It provides nearly a fourth of Canada’s farm products. Herds of beef and dairy cattle graze in rich pastures between Lake Huron and Lake Ontario. Tobacco grows along Lake Erie, and orchards thrive in the Niagara fruit belt. Northern Ontario has thick forests that provide wood for the pulp and paper industry. Trappers catch fur-bearing animals there, and campers hunt and fish.

The province’s name came from the Iroquois Indians, who lived in the Ontario region when French explorers first arrived. The word Ontario may mean beautiful lake. Or it may mean rocks standing high or near the water—referring to Niagara Falls. These spectacular falls attract many visitors. Niagara Falls ranks among the greatest natural sources of hydroelectric power in North America.

Ontario, together with New Brunswick, Nova Scotia, and Quebec, was one of the original provinces of Canada. For the relationship of Ontario to the other provinces, see Canada; Canada, Government of; Canada, History of.
Ontario in brief

Symbols of Ontario
The provincial flag, adopted in 1965, bears the British Union Flag and the shield of Ontario. The shield has the cross of Saint George, representing the province's ties with the United Kingdom. The three maple leaves symbolize Canada. The crest is a bear atop a wreath of green and gold. A moose and a deer support the shield. The shield was granted by royal warrant in 1868. The crest and supporters were granted in 1909.

Ontario ranks as the second largest province of Canada.

General information
Entered the Dominion: July 1, 1867, as one of the original four provinces.
Provincial abbreviation: ON (postal).
Provincial motto: Ut Incepit Fidelis Sic Permanet (Loyal She Began, Loyal She Remains).

The Provincial Parliament Buildings are in Toronto, the capital since 1867. The region had several other capitals as Upper Canada and part of the Province of Canada.

Land and climate
Area: 417,581 mi² (1,068,580 km²), including 68,491 mi² (177,390 km²) of inland water.
Elevation: Highest—2,275 ft (693 m) above sea level in Timiskaming District. Lowest—sea level.
Coastline: 752 mi (1,210 km).
Record high temperature: 108 °F (42 °C) at Biscotasing on July 20, 1919, at Atikokan on July 11 and 12, 1936, and at Fort Frances on July 13, 1936.
Record low temperature: −73 °F (−58 °C) at Iroquois Falls on Jan. 23, 1935.
Average January temperature: 3 °F (−13 °C).
Average yearly precipitation: 31 in (79 cm).

Important dates
- French missionaries founded Fort Sainte Marie.
- Etienne Brule of France became the first white person to explore the Ontario region.
- Britain obtained the Ontario region from France.
- Ontario became one of the original four provinces on July 1.

Economy
Chief products
Agriculture: milk, beef cattle, hogs, corn.
Manufacturing: transportation equipment, electronic equipment, metal products, food and beverage products, chemicals.
Mining: gold, nickel, copper, sand and gravel, zinc.

Gross domestic product
Value of goods and services produced in 2000: $429,530,000,000.*
Services include community, business, and personal services; finance; government; trade; and transportation and communication. Industry includes construction, manufacturing, mining, and utilities. Agriculture includes agriculture, fishing, and forestry.

Government
Provincial government
Premier: term of up to 5 years
Members of the Legislative Assembly: 103, terms of up to 5 years
Federal government
Members of the House of Commons: 103
Members of the Senate: 22

Sources of information
For information about tourism in Ontario, write to: Ontario Travel, Queen's Park, Toronto, ON M7A 2E1. The Web site at www.ontariotravel.net also provides information on tourism in the province. For information on Ontario's economy, government, and history, write to: Citizens' Inquiry Bureau, Ferguson Block, 77 Wellesley Street West, 12th Floor, Toronto, ON M7A 1N3. The Ontario government's Web site at www.gov.on.ca also provides a gateway to much information on the province's economy, government, and history.

Sources of information
- 1883: Ontario gained the territory north of the Albany River.
- 1912: The world's largest copper-nickel reserves were discovered at Sudbury.
- 1952: One of the world's largest uranium deposits was discovered at Elliot Lake.
- 1972: Ontario began a program of free medical and hospital care for the elderly and the poor.
Population. The 2001 Canadian census reported that Ontario had 11,410,046 people. The population of the province had increased about 6 percent over the 1996 figure of 10,733,573.

The great majority of Ontarians—92 of every 100 people—live in 12 percent of the province’s land area. This heavily populated region, the southernmost part of the province, lies south of Lake Nipissing. This area includes all of Ontario’s metropolitan areas except those of Greater Sudbury and Thunder Bay.

Ontario has 11 Census Metropolitan Areas as defined by Statistics Canada. For the names and populations of these metropolitan areas, see the Index to the political map of Ontario.

More than four-fifths of the people of Ontario live in cities and towns. Ontario contains more cities with populations of 50,000 or more than any other Canadian province.

Toronto is the largest city in Ontario and in Canada. Ontario’s other large cities include Brampton, Hamilton, London, Markham, Mississauga, Ottawa, and Windsor. See the list of separate articles on the cities of Ontario listed in the Related articles at the end of this article.

About three-fourths of the people in Ontario were born in Canada. The province also has many people born in Britain, Italy, the United States, and Germany. Nearly half of all Ontarians have some English ancestry. There are also many people with Scottish, Irish, and French ancestry.

Ontario has about 66,000 North American Indians. About 45 percent of the Indians live on the province’s 186 reserves. These areas cover a total of 1 1/3 million acres (710,000 hectares) in the province. Another 154,000 of Ontario’s people have some American Indian ancestry.

---

### Population density

The vast majority of Ontario’s people live in the southeast part of the province, where most of the largest cities are located. The northern areas of Ontario are thinly populated.

---

**Indians cut firewood** on an Ontario Indian reserve. About 66,000 people in Ontario are North American Indians. About 45 percent of these people live on Indian reserves.

**Yorkville** is a fashionable area of Toronto that features art galleries, boutiques, and sidewalk cafes. The district is also known for the variety of its architecture.
Schools. The first common (elementary) schools in the Ontario region were established during the late 1780's. In 1807, Ontario's provincial government provided by law for a grammar (high) school in each of the province's eight districts. In 1816, the government provided for common schools throughout the province. A royal charter was granted in 1827 for a college in York (now Toronto). This college opened in 1843 under the name of King's College and became the University of Toronto in 1850.

Ontario's school system took its present basic form during the 1870's. All common and grammar schools became free elementary and secondary schools. Attendance from age 6 to age 16 was required by law, as it still is today.

Today, Ontario has public schools and Roman Catholic schools. Both types of schools are tax supported, and both are under the jurisdiction of the Ministry of Education. English is the language of instruction in most schools. However, the province also has some French-language schools as well as a number of schools where both English and French are used. For the number of students and teachers in Ontario, see Education (table).

Libraries. Ontario's first subscription library was established in 1800 at Niagara. By 1867, when Ontario became one of the four original provinces of Canada, it had more than 60 mechanics' institutes, which provided books for working people. Ontario passed Canada's first public library legislation, the Free Libraries Act, in 1882. Today, the province contains hundreds of public libraries.

The National Library of Canada, the Canada Institute for Scientific and Technical Information, the Library of Parliament, and the Supreme Court of Canada Library are in Ottawa. The Thomas Fisher Rare Book Library of the University of Toronto includes well-known collections of Canadian, English, and Italian literature. The National Gallery of Canada Library, also in Ottawa, includes an extensive collection of visual-arts literature.

Museums. The Royal Ontario Museum in Toronto has more than 45 galleries containing archaeology, art, and science exhibits. The Ontario Science Centre, also in Toronto, features exhibits and demonstrations dealing with science and technology. National museums in Ottawa include the Canadian Museum of Nature, with collections covering botany, earth sciences, and vertebrate and invertebrate animals; the Canada Science and Technology Museum, with exhibits on astronomy, communications, outer space, technology, and transportation; and the National Gallery of Canada, which features artworks from Canada and other parts of the world.

Old Fort William in Thunder Bay is a reconstruction of a local fur-trading post of the 1800's. Sainte-Marie Among the Hurons, near Midland, is a re-creation of a fortress and headquarters for Jesuit missionaries of the 1600's. The fortress was Ontario's first European community. Ottawa's Canadian War Museum displays art, artifacts, and memorabilia representing the nation's military history. Many community museums throughout Ontario highlight local history and regional history.

### Universities and colleges

This table lists the universities and colleges in Ontario that grant bachelor's or advanced degrees and are members of the Association of Universities and Colleges of Canada.

**University College** is one of the oldest colleges of the University of Toronto and a national historic monument. The University of Toronto ranks as Canada's largest university.
More than 20 million tourists visit Ontario every year. The province has more than 250,000 lakes and rivers, which offer a variety of vacation attractions, including fishing and boating. Ontario's forests attract campers and hunters.

The sunny, southernmost resort region of the province, along Lakes Erie and Ontario, is known as Canada's Sun Parlor. Boat cruises are available to take vacationers through the Thousand Islands and other islands in Ontario waters. The Haliburton Highlands and the Kawartha and Muskoka lakes near Toronto are famous resort areas. Low, wooded hills line their shores. The landscape becomes more rugged toward the northern and northwestern vacationlands of James Bay and Lake of the Woods. Many hunters fly in seaplanes to the far northern lakes to hunt bear, geese, moose, and a variety of other game.

Ontario is the home of two major annual drama festivals. The Stratford Festival, held in Stratford, features the plays of William Shakespeare. The Shaw Festival, at Niagara-on-the-Lake, presents plays by George Bernard Shaw and other dramatists of his time.

Horseshoe Falls, the largest part of Niagara Falls, near the Ontario-New York border

Places to visit

Following are brief descriptions of some of Ontario's many interesting places to visit:

Agawa Canyon, near Sault Ste. Marie, is a scenic wilderness area with waterfalls, mountains, ravines, and forests.

Black Creek Pioneer Village, in Toronto, is an open-air museum that re-creates rural life in Ontario in the 1800's. The village includes houses, farm buildings, workshops, and an inn.

CN Tower, in Toronto, is the world's tallest free-standing structure.

Horseshoe Falls, near the Ontario-New York boundary, is the largest part of Niagara Falls. It is about 2,600 feet (792 meters) wide and 167 feet (51 meters) high.

Old forts in Ontario that have been restored include Fort Erie in Fort Erie, Fort George in Niagara-on-the-Lake, Fort Henry in Kingston, Fort Malden in Amherstburg, Fort St. Joseph on St. Joseph Island, Fort Wellington in Prescott, Fort York in Toronto, and Old Fort William in Thunder Bay.

Ontario Place, in Toronto, is a cultural, recreational, and entertainment complex that features concerts, a giant-screen movie theater, an exhibition area, and facilities for boating and picnics. It lies on artificially created islands in Lake Ontario.

Parliament Buildings, in Ottawa, are three Gothic-style stone buildings with green copper roofs. They form Canada's seat of government. The Changing of the Guards ceremony takes place in front of these buildings in July and August.

Royal Botanical Gardens, in Burlington, attract many visitors from around the world. The botanical gardens were established in 1941.

Sainte-Marie Among the Hurons, near Midland, is a reconstructed Jesuit mission of the 1600's. Martyrs' Shrine, which stands nearby, honors six missionaries who were martyred by the Iroquois.

Upper Canada Village, near Morrisburg, shows life in Ontario from 1784 to 1867. Some of its buildings were moved from the Lake St. Lawrence area.

National parks. Ontario has five national parks—Bruce Peninsula, between Lake Huron and Georgian Bay; Georgian Bay Islands, in Georgian Bay; Point Pelee, on the Lake Erie peninsula; Pikiska, on the shore of Lake Superior; and St. Lawrence Islands, along the St. Lawrence River. Ontario also has eight national historic parks and sites and one national marine park—Fathom Five in Georgian Bay. For the area and main features of the national parks in Ontario, see Canada (National Park System).

Provincial parks. Ontario has more than 230 provincial parks. Most provide camping facilities and waterside ramps for small boats. For information, write to: Ministry of Natural Resources, Ontario Parks, Whitney Block, #6540, 99 Wellesley Street West, Toronto, ON M7A 1W3. The Web site maintained by Ontario Parks at www.OntarioParks.com also has helpful information on provincial parks in Ontario.
Annual events

January-March
International Boat Show in Toronto (January); winter carnivals provincewide (January-February); Toronto Sportsman's Show (March); Maple Syrup Festivals throughout southern Ontario (March-April).

April-June
Shaw Festival in Niagara-on-the-Lake (April-October); Guelph Spring Festival (May); Canadian Tulip Festival in Ottawa (May); Stratford Festival (May-November); Heritage Festival in Timmins (June); Thunder Bay Children's Festival (June); Jazz Festival in Toronto (June); London Air Show and Balloon Festival (June).

July-September
International Freedom Festival, in Windsor and Detroit (July); Molson Indy automobile race in Toronto (July); Mariposa Folk Festival in Orillia (July); Festival of the Sound in Parry Sound (July-August); Caribana in Toronto (July-August); Rockhound Gemboree in Bancroft (July-August); Six Nations Native Pageant near Brantford (August); Canadian National Exhibition in Toronto (August-September); Toronto International Film Festival (September); Niagara Grape and Wine Festival in St. Catharines (September).

October-December
Oktoberfest in Kitchener-Waterloo (October); Royal Agricultural Winter Fair in Toronto (November); Niagara Falls Festival of Lights (November-January).
Land regions. Ontario has four main land regions. They are, from north to south: (1) the Hudson Bay Lowland, (2) the Canadian Shield, (3) the St. Lawrence Lowland, and (4) the Great Lakes Lowland.

The Hudson Bay Lowland curves around the southern part of Hudson Bay and extends as far south as Kesagami Lake. This flat region of northern Ontario is poorly drained, and has large muskegs (peat bogs). The lowland includes a narrow belt of permafrost (permanently frozen ground) near the Arctic.

The Canadian Shield is a vast, horseshoe-shaped region that covers almost half of Canada and part of the northern United States. This low, rocky region covers more than half of Ontario. Small lakes and rivers surrounded by wooded hills attract many vacationers. The highest point in Ontario rises 2,275 feet (693 meters) in Timiskaming District.

The Canadian Shield is rich in game, minerals, and timber. Patches of clay are scattered throughout the region. These areas were formed by deposits in ancient glacial lakes. The largest clay area, known as the clay belt, extends from the Hearst area to the Quebec border. Farmers raise a variety of crops, including grains and vegetables, in the rich clay soil. Beef and dairy cattle graze on fenced grasslands in the region. See Canadian Shield.

The St. Lawrence Lowland runs along the St. Lawrence River. In Ontario, it forms the tip of the wedge of land between the Ottawa and St. Lawrence rivers. Low hills rise above the fertile valleys. Farmers grow fruits, grains, and vegetables in this region. Dairy farming is extensive there.

The Great Lakes Lowland lies along much of the Great Lakes in Canada and the United States. In Ontario, the region touches Lakes Erie, Huron, and Ontario. Great quantities of many crops are grown in the fertile gray-brown soil of the low, flat, southwestern section. The land rises gently in the northeast, where beef and dairy cattle are raised. The Niagara Escarpment, a high cliff or ridge, extends 250 miles (402 kilometers) from Manitoulin Island, through Bruce Peninsula, to Niagara Falls. The escarpment forms a natural shelter for Ontario's best farmers and growing region.
The St. Lawrence River, a great natural highway for commerce, has contributed much to the growth of Ontario's economy. This waterway was enlarged during the 1950's to allow ocean vessels to reach the Great Lakes. Hydroelectric plants on the Niagara and other rivers provide Ontario with cheap power. The mighty Horse-shoe Falls are formed by the Niagara River passing over the Niagara Escarpment.

The Ottawa River was part of the route of the early fur traders to Georgian Bay and the west. This river flows into the St. Lawrence River. The Ottawa drains the part of southern Ontario that does not lie in the Great Lakes basin. Other important southern rivers include the

French, Grand, Thames, and Trent. The Detroit and St. Clair rivers are links between Lakes Erie and Huron. Lakes Huron and Superior are joined by the St. Marys River.

Ontario has about 400,000 lakes. Besides the Great Lakes, the largest lakes in the province are Lake of the Woods, Lake Abitibi, Lake Nipigon, Lake Nipissing, and Lake Seul.

**Plant and animal life.** Ontario has about 180,000 square miles (466,000 square kilometers) of forests. Northern Ontario has huge forests of balsam, pine, spruce, and other softwoods. It also has birch and poplar. Thick forests of hardwoods such as ash, beech, elm, maple, and walnut once covered the southern part of the province. Most of the timber in the south was cut during the 1800's, and the forests there now have second-growth trees.

Wild flowers are plentiful in Ontario. Trilliums and bloodroots blossom in spring. Autumn brings masses of asters and wild carrot blooms. Northern lakeside hills are thick with wild blueberry bushes in forest clearings. Shrubs and mosses grow in the far northern areas, where frost stays deep in the ground. Tamarack and spruce, which grow there, do not reach their usual height in this cold, poorly drained region.

Moose and caribou roam the wooded northlands of Ontario. Shy white-tailed deer pause to drink from streams in the Canadian Shield. People in this region often see the tracks of black bears. Fur-bearing animals such as beavers, minks, muskrats, foxes, and otters live throughout Ontario. Snowshoe hares are also plentiful in all parts of the province. Raccoons and rabbits are abundant in southern Ontario. Birds of Ontario include ducks, geese, and ruffed grouse. The haunting cries of loons pierce the air at dusk over Ontario's lakes. Brook trout, lake trout, northern pike, whitefish, and yellow pickerel are found in the lakes and rivers.

**Climate.** Winds from the Great Lakes give southern Ontario a milder climate than the rest of the province. Northern Ontario gets cold waves from the Arctic, or from the northwestern prairies. The record high temperature, 108° F. (42° C), occurred in Biscotasing on July 20, 1919, in Atikokan on July 11 and 12, 1936, and in Fort Frances on July 13, 1936. The lowest temperature, —73° F. (—58° C), occurred in Iroquois Falls on Jan. 23, 1935.

**Abitibi,** near Tempe, is a large wilderness area of beautiful lakes and dense forests. Many people visit the park to enjoy camping, canoeing, and fishing.

Quetico Provincial Park, near Atikokan, is a large wilderness area of beautiful lakes and dense forests. Many people visit the park to enjoy camping, canoeing, and fishing.
The average January temperature in southern Ontario ranges from 12 °F (−11 °C) in Ottawa to 23 °F (−5 °C) in Windsor. The average July temperature is 66 °F (19 °C) in Greater Sudbury and 72 °F (22 °C) in Windsor. The temperature in northern Ontario in January averages −11 °F (−24 °C) at Big Trout Lake and −4 °F (−20 °C) at Moosonee. The temperature in July averages 61 °F (16 °C) at Big Trout Lake and 66 °F (19 °C) at Sioux Lookout.

Ontario's average annual precipitation (rain, melted snow, and other moisture) ranges from 24 to 28 inches (60 to 70 centimeters) in the northern part of the province to 31 to 35 inches (80 to 90 centimeters) in the southern part. Annual snowfall in most of Ontario ranges from 48 to 105 inches (123 to 267 centimeters).

The highly developed industries of Ontario make it one of the richest economic regions of North America. Service industries make up the largest part of the province's gross domestic product (GDP)—the total value of goods and services produced in the province in a year. Ontario has a higher GDP than any other province. Ontario leads the provinces in business and high-technology services and in the manufacture of high-technology and industrial products.

The economy of Ontario benefits from the province's location near key North American population centers and waterways. Ontario is close to many large U.S. cities, which provide markets for the province's goods and services. Several major U.S. corporations have large operations in Ontario. The St. Lawrence Seaway provides Ontario's Great Lakes ports with an outlet to the Atlantic Ocean. Thus, ships can travel to and from Ontario ports from any ocean port in the world.

Natural resources. The great forests and abundant wildlife of Ontario are valuable natural resources. Other important resources of the province include fertile soils, many mineral deposits, and a plentiful water supply.

Soil. The soils of the northernmost parts of Ontario are frozen the year around. The Hudson Bay Lowland's soils consist mostly of clay and marshes of moss called muskeg. Thin soils cover ancient rock in most of the Canadian Shield. Near the Quebec border, glacial clays and silt cover the fertile clay belts of the Cochrane and Temiskaming districts. The St. Lawrence and Great Lakes lowlands are Ontario's chief farming regions. The St. Lawrence Lowland has black loams and well-drained sands over limestone and shale. The Great Lakes Lowland has rich, sandy soils.

Minerals are found throughout central and northern Ontario in the rocks of the Canadian Shield. The Sudbury Basin, in the southern part of the shield, is the greatest single source of Ontario's mineral wealth. About one-eighth of the world's nickel comes from this district. The ores there also contain cobalt, copper, gold, platinum, and silver. Other areas in the Canadian Shield produce copper, gold, nickel, and zinc. The three Hemlo area mines, on the north shore of Lake Superior, produce over 800,000 troy ounces (25,000 kilograms) of gold annually. The province's other mined products include cement, lime, salt, sand and gravel, and stone.

Service industries, taken together, account for about two-thirds of Ontario's GDP and employ nearly three-fourths of the province's workers. Service industries are
especially important in the major urban areas of southern Ontario.

Community, business, and personal services form the most valuable service industry group in Ontario. This industry sector employs more than a third of the province's workers. Community, business, and personal services include such economic activities as education and health care, professional and scientific services, and the operation of hotels and recreational facilities. Large universities at Hamilton, London, Ottawa, Toronto, and Waterloo employ many people. Many of Canada's largest hospitals, law firms, and hotels are in Toronto. Hotels and many other service establishments benefit from tourist spending. Each year, more tourists visit Ontario than any other Canadian province.

Finance, insurance, and real estate form the second most important service industry group in Ontario in terms of the gross domestic product. Toronto is the nation's leading financial center. Most of Canada's largest banks, insurance companies, and property developers are headquartered there. The Toronto Stock Exchange is one of the largest in North America. Rapid population growth in such metropolitan areas as Kitchener, Oshawa, Ottawa, and Toronto has benefited Ontario's real estate companies by increasing the demand for housing in the province.

Wholesale and retail trade ranks third among Ontario service industry groups in terms of the gross domestic product. The wholesale trade of groceries and of motor vehicles are especially important. Leading types of retail establishments include auto dealerships, department stores, food stores, gas stations, and restaurants.

Transportation and communication rank next among Ontario's service industry groups. Large shipping and trucking companies are based in southern Ontario. Lester B. Pearson International Airport, Canada's busiest air terminal, lies just outside Toronto. Telephone companies are the largest part of the communication industry. More information about transportation and communication can be found later in this section.

Government ranks fifth. Provincial government activities are based in Toronto, and federal government activities are based in Ottawa.

Manufacturing is Ontario's single most important economic activity in terms of the gross domestic product. Goods manufactured in Ontario have a value added by manufacture of about 115 billion Canadian dollars yearly. This amount represents the difference between the value of raw materials and the value of finished products made from the raw materials.

About half of Canada's industrial workers live in Ontario. These workers produce about half the country's manufactured products. The Toronto area ranks as Canada's leading industrial center.

The production of transportation equipment is Ontario's chief manufacturing industry. Automobile manufacturing is the main part of this industry. Most of Canada's automobile manufacturing takes place in Ontario. Several major automobile companies have large assembly plants in southern Ontario. Many trucks are also produced in the province. Motor vehicle manufacturing takes place in Alliston, Bramalea, Cambridge, Ingersoll, Oakville, Oshawa, St. Thomas, and Windsor.

Electronic and electrical equipment rank next among Ontario's manufactured products. Telecommunications and computer equipment are the leading types of electronic equipment made in Ontario. Electric appliances are also important. The manufacture of electronic equipment is based mainly in the Toronto and Ottawa areas.

Metal products rank third among the province's manufactures. The leading types of fabricated metal products are structural metal, automobile body parts, and hardware. Steel mills account for most of the primary metal production. Hamilton and Sault Ste. Marie are Ontario's major steel centers.

Food and beverage processing ranks fourth among Ontario's manufacturing activities. Toronto is a major North American meat-packing center. Fruits and vegetables grown in the Great Lakes region of Canada are processed in Ontario factories. Plants in the province produce much milk and other dairy products. Ontario's
Economy of Ontario

This map shows the economic uses of land in Ontario and where the province’s leading farm, mineral, and forest products are produced. The major urban areas (shown on the map in red) are Ontario’s important manufacturing centers.

![Ontario Economy Map]

mills process Canadian-grown wheat into flour and prepared baking mixes. Beer, soft drinks, and liquor are the leading beverages produced in Ontario.

The production of chemicals ranks fifth among Ontario’s manufacturing activities. The leading types of chemicals produced in the province are industrial chemicals, pharmaceuticals, and fertilizers.

Other products manufactured in Ontario include machinery, paper products, and printed materials. Construction and mining equipment are the leading types of machinery manufactured in the province. Large paper mills operate in the Niagara Falls area and in Thunder Bay. Print shops and newspaper publishing companies turn out most of the province’s printed materials.

Agriculture. Ontario has about 67,000 farms. The farms cover about 14 million acres (6 million hectares)—about 5 percent of the province’s land area.

Livestock and livestock products provide about 55 percent of Ontario’s farm income. Milk is the leading source of farm income. The raising of beef cattle and hogs rank second and third in importance. Beef and dairy cattle graze on pastureland between the southeastern shores of Lake Huron and the lower western shores of Lake Ontario. Dairying is also important eastward along Lake Ontario and the St. Lawrence River. Farmers in southern Ontario raise large numbers of hogs.

Ontario farmers grow the feed crops they need for their livestock. The major crops include corn, hay, soybeans, and wheat. Ontario leads the provinces in the production of eggs and poultry.

Ontario is also Canada’s leading producer of fruits and vegetables. Orchards and vineyards of the famous Niagara fruit belt produce apples, grapes, peaches, strawberries, and other small fruits. The chief vegetables grown in the province include beans, cabbage, carrots, cucumbers, mushrooms, onions, peppers, potatoes, sweet corn, and tomatoes. Tobacco, which grows along Lake Erie, is among the leading cash crops in Ontario.

Ontario also has the largest floriculture industry in Canada. Many growers raise flowers and vegetables indoors to protect the plants from the weather and to control the growth of the plants. Greenhouses cover about 2,000 acres (810 hectares) in the province. Many flowers and plants raised in the province’s greenhouses are exported to other countries including the United States.

Mining. Most of Ontario’s mining income comes from the production of metal ores. The province produces about a third of Canada’s metallic minerals.

Gold, nickel, and copper are Ontario’s most valuable mineral products. Gold-producing regions are located throughout the Canadian Shield region. The single leading gold-producing area is the Hemlo gold field, which is near Marathon. The Greater Sudbury area is Canada’s center of nickel production. Mines in the Greater Sudbury and Timmins areas produce most of Ontario’s copper.

Other leading mined products in Ontario include petroleum products, sand and gravel, stone, and zinc. Natural gas and petroleum have been found in southern Ontario and beneath the waters of Lake Erie. Sand and gravel are obtained primarily from pits in the southeastern part of the province. Granite, limestone, and marble
from Ontario grace buildings around the world. Zinc is mined in the Timmins area. Other mined products found in Ontario include cement, clay, cobalt, gypsum, lime, magnesium, platinum, salt, and silver.

Electric power and utilities. Nuclear power plants produce about half of Ontario's electric power. Hydroelectric plants supply about a fourth. Fuel-burning plants also produce about a fourth. Ontario has about 70 hydroelectric plants, 6 fuel-burning electric stations, and about 10 nuclear power plants. Ontario and the state of New York share the water of Niagara Falls under terms of a 1910 treaty between Canada and the United States. Other utility companies provide the province’s people with gas and water service.

Transportation. Waterways have played an important part in the history of Ontario. French explorers traveled up the Ottawa River in canoes. Early canals, particularly the Rideau and Trent systems, carried passengers and freight. The St. Lawrence Seaway, which was completed in 1959, brought ocean-going ships to the inland ports (see Saint Lawrence Seaway).

During the navigation season, from late March or early April to late December, many freighters travel between the ports of Ontario and those of the United States. Grain-carrying ships crowd the docks of Thunder Bay on Lake Superior. Ontario has 540 miles (869 kilometers) of canals, with over 100 locks. The Trent Canal is a recreational canal which extends 240 miles (386 kilometers) between Trenton and Georgian Bay.

Lester B. Pearson International Airport, just outside Toronto, is the largest and busiest airport in Canada. A number of government, industrial, and private airlines carry passengers and supplies to distant mining and lumbering camps in the northern part of Ontario.

Ontario has about 7,800 miles (12,500 kilometers) of railways, about a fourth of Canada's total. Southern Ontario has Canada's finest railway network. Toronto is the province's chief rail center. The Canadian National Railway, the Canadian Pacific Railway, and VIA Rail are the largest railways in Ontario. The province owns the Ontario Northland Railway, whose main line runs through the clay belt and the silver-mining region to James Bay. A government-owned rail and bus system serves over 100,000 commuters in Toronto each weekday.

About 13,400 miles (21,600 kilometers) of highways crisscross the province. Nearly all of these highways are paved. Part of the east-west Trans-Canada Highway runs across Ontario. A 510-mile (821-kilometer) expressway stretches from Windsor to the Quebec border.

Communication. Louis Roy, a Frenchman from Quebec, published the first newspaper of the Ontario region. His paper, the Upper Canada Gazette, or American Oracle, first appeared in 1793 in Newark (now Niagara-on-the-Lake). York (now Toronto) became the capital of Ontario in 1797, and the Gazette moved there in 1798. It was published until 1849.

Ontario's first radio station, CKOC, began broadcasting in Hamilton in 1922. The first TV station, CBLT, was founded in Toronto in 1952. Today, Ontario has about 170 radio stations and 20 TV stations. Cable television systems and Internet providers serve many Ontario communities.
Lieutenant governor of Ontario represents the British monarch, Queen Elizabeth II, in her role as the queen of Canada. The lieutenant governor is appointed by the governor general in council of Canada. The position of lieutenant governor is largely honorary.

Premier is the actual head of government. Ontario, like the other provinces and Canada itself, has a parliamentary government. The premier is an elected member of the Legislative Assembly and is usually leader of the Assembly's majority party. The head of Ontario's government was called the premier until 1906, when the title was changed to prime minister. In 1972, Prime Minister William Davis changed the title back to premier.

The premier presides over the Executive Council (cabinet). The Executive Council includes ministers chosen by the premier from members of the premier's party in the Assembly. Each minister directs a government ministry, except a small number who are called associate ministers. The Executive Council, like the premier, resigns if it loses the support of a majority of the Assembly.

Legislative Assembly is a one-house legislature that makes the provincial laws. It has 103 members who are elected from 103 electoral districts called constituencies. Their terms may last up to five years. However, the lieutenant governor, on the advice of the premier, may call for an election before the end of the five-year period. All members may run again for office.

Courts. Ontario's highest court is the Court of Appeal. It consists of a chief justice, an associate chief justice, and 16 other justices.

The rest of the court system, called the Ontario Court of Justice, is divided into the General Division and the Provincial Division. The General Division hears major civil, family, and criminal cases. It has a chief justice, an associate chief justice, regional senior judges, and about 200 other judges. This division also contains the Divisional Court, the Family Court, and the Small Claims Court. The Divisional Court hears reviews of provincial administrative action and some General Division appeals. The Family Court hears all aspects of family law disputes. The Small Claims Court hears minor civil cases. General Division justices are appointed by Canada's governor general in council and serve until age 75.

The Provincial Division handles provincial offenses and some family and young offenders cases. The Provincial Division has a chief judge, 2 associate chief judges, regional senior judges, and over 250 other judges. The judges are appointed by the provincial lieutenant governor in council and serve until age 65.

Local government. Ontario has three basic municipal units: upper-tier municipalities (regions, counties, and the District of Muskoka); lower-tier municipalities (cities, towns, villages, and townships); and single-tier municipalities (areas where there is only one level of municipal government).

Since 1996, the province's municipal structure has undergone considerable change. The number of municip-

The Legislative Assembly meets in the main Provincial Parliament Building in Toronto. Each of the Assembly’s 103 members serves a term of up to five years.

Andrew McKeith, McMaster
palties in Ontario has been reduced from 815 to 447. The number of regional municipalities has been reduced from 13 to 8, and the single-tier municipalities of Toronto, Greater Sudbury, Hamilton, Ottawa, Halldimand County, and Norfolk County have been created. Outside the major cities, many lower-tier municipalities have been amalgamated (combined) within existing counties. In some cases, this amalgamation has resulted in the transformation of entire counties into new single-tier municipalities. Despite the amalgamations, about half of Ontario's municipalities still have populations of less than 5,000, and much of northern Ontario remains sparsely settled with no municipal organization.

Municipalities provide many local and regional services. In southern Ontario, counties, regional municipalities, and cities have been designated to provide a range of social services and housing. In the northern part of the province, district boards provide health and social services to municipalities and to areas without municipal organization.

Revenue. Taxes collected by the provincial government provide about three-fourths of the province's general revenue (income). Most of this money comes from personal and corporate income, retail sales, payroll, and gasoline sales.

Politics. The province has three major political parties. They are the Progressive Conservative, Liberal, and New Democratic parties. The Progressive Conservative Party was formerly named the Conservative Party, and today its members are usually called simply Conservatives.

Ontario's first provincial government was a coalition (combination) of Liberals and Conservatives. The Liberals took full control of the government in 1871 and held it until 1905, when the Conservatives came to power. In 1919, during an economic depression, the United Farmers of Ontario took over the government. The Conservatives regained leadership in 1923 after the economy improved, but they lost it to the Liberals in 1934.

The Progressive Conservatives won control of the government in 1943. They held power until 1985, when the Liberals assumed control. The New Democratic Party gained control of the government in 1990. In 1995, the Progressive Conservatives again won power. Ontario citizens must be at least 18 years of age to vote in federal or provincial elections.

History

Indian days. Three major Indian groups lived in what is now Ontario when white explorers first arrived. Chippewa Indians hunted beavers and small game in the forests north and east of Lake Superior. Huron Indians lived between Lake Huron and Lake Ontario. They depended mainly on cultivated crops for food. The Chippewa and Huron feared wandering bands of Iroquois Indians, who sometimes raided their camps.

Exploration. The first white person to explore the Ontario region was Etienne Brulé of France. He was sent in 1610 by Samuel de Champlain, the founder of Quebec. In 1613, Champlain paddled up the Ottawa River. He journeyed farther south in 1615, into the Lake Huron area. Champlain found this region rich in fur-bearing animals. Young French fur traders followed his course to collect pelts. They traveled deep into the forests, and traded beads and knives to the Indians for furs. In the 1620's and 1630's, other French explorers, including Brulé and Jean Nicolet, traveled farther than Champlain. They explored the Lake Superior region, Lake Michigan, and beyond. See Champlain, Samuel de.

Early settlement. French missionaries followed the fur traders into the Ontario region. In 1639, Jesuit priests built Fort Sainte Marie as the center of a group of missions. These missions, known as Huronia, were established among the Huron Indians. The Iroquois Indians forced the Jesuits to abandon the missions in 1648 and 1649. During the 1650's and 1660's, French explorers entered the region north of Lake Superior. These explorers included Pierre Esprit Radisson and Médard Chouart, Sieur des Groseilliers. Their explorations led to the founding of the Hudson's Bay Company in London (see Hudson's Bay Company).

In 1763, at the end of the French and Indian War, France gave the Ontario region to Britain. By then, there were only a few scattered French settlements near what are now Kingston, Niagara Falls, and Windsor. Little further settlement took place until 1784. That year, after the Revolutionary War in America, people loyal to England began arriving from the United States. About 6,000 of these United Empire Loyalists, as they were called, had arrived by 1785. They settled west of the Ottawa River. The Loyalists had lost their homes and wealth. The British government gave them food, clothing, land, livestock, and seed. About 4,000 other settlers also arrived from the United States. See United Empire Loyalists.

Upper Canada. In 1791, the southern part of what is now Ontario became the separate colony of Upper Canada. Newark (now Niagara-on-the-Lake) was the capital. The British government appointed a lieutenant governor to govern the colony. The lieutenant governor appointed a 7-member legislative council, and the people elected a 16-member legislative assembly. Colonel John Graves Simcoe, the first lieutenant governor, promoted roadbuilding and expanded settlement. In 1793, Simcoe chose York (now Toronto) as the site for a new capital, and the government completed moving there in 1797.

Gradually, more settlers arrived, some in organized groups. Others were brought by land-development firms, such as the Canada Company. These settlers were assigned farms on land owned by the companies. Many Americans who liked frontier life or wanted more land also came. Sometimes whole communities moved north. A group of Pennsylvania Dutch, for example, settled near what is now Kitchener. Traders from the Hudson's Bay Company posts in the far north settled with their families in the southern towns. Most of these people were Scottish or English.

The War of 1812 between Britain and the United States began 21 years after Upper Canada was created. More than half the people of the colony were former Americans. However, most of them were loyal to their new homeland. British and Canadian troops halted invading United States forces in several battles in Upper
Historic Ontario

Étienne Brulé of France was the first white person to explore the Ontario region. He was sent in 1610 by Samuel de Champlain, the founder of Quebec.

The Welland Ship Canal, which opened in 1829, links the Great Lakes shipping lanes with the St. Lawrence River.

Thousands of slaves fled from the United States to Ontario in the 1850's. Antislavery leader John Brown had many followers around Chatham.

A rebellion in 1837 was led by William Lyon Mackenzie, a former member of the Legislative Assembly. A colonial militia put down the uprising. Several rebels were executed or imprisoned.

Important dates in Ontario

1610 Étienne Brulé of France became the first white person to explore the Ontario region.
1613 Samuel de Champlain of France explored the Ottawa River area.
1639 French missionaries founded Fort Sainte Marie.
1648-1649 Indians destroyed the French missions.
1763 The Ontario region became a British possession.
1791 The region became the province of Upper Canada.
1812-1814 American forces invaded Upper Canada during the War of 1812.
1837 A rebellion against British rule broke out in Upper Canada.
1867 Ontario became one of the original four provinces of the Dominion of Canada on July 1.
1883 The world’s largest copper-nickel reserves were discovered at Sudbury (now part of Greater Sudbury).
1904 Ontario’s automobile industry began in Windsor.
1912 Ontario gained the territory north of the Albany River.
1952 The Western world’s largest uranium deposit was discovered at Elliot Lake.
1959 The St. Lawrence Seaway opened.
1964 A huge field of copper, silver, and zinc was discovered near Timmins.
1972 Ontario began a program of free medical and hospital care for the elderly and the poor.
1982 Large gold deposits were discovered at Hemlo, near Marathon.
1985 Liberals, supported by New Democrats, gained control of the government, after 42 years of Progressive Conservative rule.
1990 The New Democratic Party gained control of the government.
1995 The Progressive Conservatives regained control of the government.
Canada. See War of 1812 (Chief battles of the war).

**Early industrial growth.** The population of Upper Canada grew rapidly during the 1820's. Towns such as Bytown (now Ottawa) became thriving centers of trade. Canals, mills and small factories, and roads were built. The Rideau, Trent, and first Welland canals date from this period. In 1825, the Erie Canal linked Lakes Erie and Ontario with New York City. Large groups of immigrants, most of them from Ireland, came after these transportation improvements were made.

**Political unrest.** During the 1830's, Upper Canadians became greatly dissatisfied with their government. They elected only the Legislative Assembly. The real power lay with the lieutenant governor, who was appointed by the British government. The lieutenant governor appointed the Legislative Council and the Cabinet. The Legislative Council generally represented the wealthy and powerful persons of the colony. The council often blocked legislation that the people wanted and the assembly had passed. This legislation included building new roads and schools, and providing free land to settlers.

Both the colonial and British governments ignored demands for political reform. William Lyon Mackenzie, a member of the Legislative Assembly, and a small group of followers rebelled in 1837. A colonial militia put down the uprising. Several rebels were executed, some were imprisoned, and others, including Mackenzie, fled to the United States. See **Rebellions of 1837**.

In 1840, the British Parliament passed the Act of Union. This act, which took effect in 1841, united Upper Canada and Lower Canada (part of present-day Quebec) into a single colony called the Province of Canada. In 1848, the colony gained **responsible government**. Under responsible government, a Cabinet is chosen from a party or group that can command the support of a majority in the elected assembly. The governor acts on the advice of the Cabinet in local matters.

**Confederation.** In 1864, politicians from the Province of Canada proposed a federal union of all the British colonies in eastern North America. All except Prince Edward Island and Newfoundland agreed to join the confederation. On July 1, 1867, the British North America Act created the Dominion of Canada. New Brunswick, Nova Scotia, Ontario, and Quebec became provinces in the Dominion. Ottawa was made the federal capital, and Sir John A. Macdonald of Ontario became the first prime minister of Canada. John S. Macdonald, unrelated to him, was the first premier of Ontario. See **British North America Act**.

**Progress as a province.** Ontario's economy grew slowly during the depression that followed confederation. Farming increased with the development of scientific methods and the use of machinery. Lumbering expanded in the Canadian Shield. During the 1880's, construction of the Canadian Pacific Railway and extension of canals helped attract settlers to western Ontario. Manufacturing increased, but many Ontarians moved to the United States for better job opportunities. In 1883, the world's richest copper nickel deposits were found near Sudbury (now part of Greater Sudbury). Major mining did not begin until after 1892, when a practical process for separating copper and nickel was developed.

**The early 1900's.** The long depression ended in 1897, and manufacturing began to increase rapidly. Cobalt became a thriving mining center after a huge silver deposit was discovered near the city in 1903. Extensive mineral exploration took place throughout the Canadian Shield. Within a few years, many new deposits of gold, silver, and other minerals were discovered. The region became one of the world's richest mining areas.

A pulp and paper industry developed in Ontario during the early 1900's, and it soon grew to major importance. Ontario's automobile industry began in 1904, when ferryboats first carried automobile parts across the Detroit River from Detroit, Michigan, to Windsor. Windsor became an automobile assembly center. In 1906, the provincial government established the Hydro-Electric Power Commission of Ontario. This agency developed Niagara Falls and other hydroelectric sources.

In 1912, Ontario's northern boundary was extended from north of the Albany River to Hudson and James bays. This action gave the province its present area. The outbreak of World War I (1914-1918) hastened Ontario's economic growth. Ontario led the provinces in the production of weapons and other military supplies.

During the 1920's, after a short depression, old cities became larger and new ones grew in number. Prospectors developed new mines in the northern forest regions. Many Finns, Scandinavians, and French-speaking Canadians from Quebec settled in these regions. Automobile production continued to grow. The iron and steel and the pulp and paper industries prospered. The prosperity ended with the Great Depression of the 1930's. During the 1930's, many Jewish families escaped Nazi persecution in Germany and came to Ontario.

**The mid-1900's.** During World War II (1939-1945), Ontario's factories, farms, and mines increased production to help arm and feed the Allied armies. Later, hundreds of thousands of Europeans left their war-torn countries and came to live in Ontario. More than half of the 3 million people who settled in Canada between 1945 and 1970 made their homes in Ontario. Ontario's population rose from about 4 million to 7 1/2 million.

In 1945, Canada's first nuclear reactor went into operation near Chalk River. Laboratories there worked to find ways to develop cheap nuclear power for Ontario's expanding industries. By 1960, the station had five experimental reactors and other research facilities, including a particle accelerator.

Ontario experienced its greatest economic growth after World War II (1939-1945). By the early 1950's, Ontario's manufacturing production had doubled. Discoveries of various minerals contributed to the economic boom. In 1952, one of the world's largest single uranium ore deposits was found at Elliot Lake. In 1953, prospectors found another huge uranium deposit near Bancroft and a rich zinc-copper field at Lake Manitouwadge.

Also during the 1950's, pipelines were laid to carry natural gas and oil to Ontario from western Canada. The oil, piped to Sarnia, led to the development of that city's great refining industry. Ontario's iron and steel industry grew rapidly. Ontario also expanded hydroelectric stations at Niagara Falls and other sites.

Ontario's economic growth continued during the 1960's. Factory production again doubled. The province's growing industries required great increases in
electric power. Ontario began to make use of nuclear power research conducted at the Chalk River reactor. Canada's first nuclear power station, at Rolphston, began operating in 1962. Its success led to the development of the nation's first full-scale nuclear station, which began operating at Douglas Point in 1967. A nuclear plant at Pickering began operations in 1971.

Many other research programs were started to promote Ontario's industrial growth. In 1966, the Sheridan Park Research Community, consisting of several private industries, set up the first of its multimillion dollar facilities near Toronto. In 1964, a huge field of copper, silver, and zinc ores was discovered near Timmins. An open-pit mine began operating there in 1966.

In 1965, Canada and the United States signed a pact on car manufacturing. Under this agreement, Canadian and U.S. companies would produce different automobile lines for sale in each of the two countries. The 1970's and 1980's. Ontario's strong economic growth helped Toronto to emerge as Canada's leading financial center in the 1960's and 1970's. Most banks and many other financial institutions and Canada's major stock exchange have their headquarters in Toronto.

Tourism became increasingly important to Ontario's economy. The province's woods and lakes have drawn growing numbers of vacationers. Historic sections of Toronto and other Ontario cities also attract visitors.

In 1972, Ontario began to provide free medical and hospital care for people aged 65 and older and for the poor. During the 1970's and 1980's, Canada suffered an economic recession. But because of the diversity of Ontario's economy, the province was hurt less and recovered more rapidly than did most provinces of Canada.

In 1982, large gold deposits were discovered at Hemlo, near Marathon. Mining of gold ore began in 1983.

Recent developments. In 1994, the North American Free Trade Agreement (NAFTA) went into effect. The pact created a regional trading bloc between Canada, Mexico, and the United States. It was built on a free-trade agreement between the United States and Canada that became effective in 1989. NAFTA calls for the gradual elimination of tariffs and other trade barriers.

The free trade agreements removed government restrictions against U.S. imports, thus creating greater competition for Ontario manufacturers. Provincial officials are focusing efforts on ensuring that, under free trade, American companies with Ontario branches do not begin to import goods rather than continuing to produce them within Ontario. Many Ontarians would lose their jobs if these U.S. branches ceased operations.

The province faced a growing budget deficit during the 1980's and early 1990's. In provincial elections held in 1995, the Progressive Conservatives won a large majority of seats in the Ontario legislature, and Michael D. Harris became premier. In an effort to reduce the deficit, Harris introduced a wide range of cuts in spending on government programs. For example, he reduced funding for welfare, cities, health care, and education. In addition, as part of his strategy to produce jobs, he cut the province's income tax rate. Although Harris's economic program created a large amount of controversy, the Conservatives again won a majority of seats in the Ontario legislature in elections held in 1999. In March 2002, the Conservatives elected Ernie Eves to replace Harris.

In 1997, Ontario's legislature voted to merge the members of the Municipality of Toronto into a single city of Toronto. The merger took effect in 1998. In 1999, the legislature enacted another municipal merger law that affected a number of Ontario communities. For example, the cities of Ottawa, Hamilton, and Sudbury were merged with surrounding communities and rural areas to form enlarged cities. These mergers took effect at the beginning of 2001.

Ontology. See Philosophy (Metaphysics).

Onyx, *AHN ihts*, is a term used loosely to apply to a banded carbonate rock and also to agate, a fine-grained variety of quartz (see Agate).

Ordinary onyx of quartz is black and white, green and white, or red and white, and so on. *Sardonyx* is a reddish-brown and white onyx. Onyx is hard and takes a high polish. It is widely used in the carving of cameos and intaglios. Today, jewelers refer to single-color agate as onyx. When they speak simply of onyx, they mean the black stone.

Onyx marble. *Mexican onyx* is a variety of calcite rock found on the walls of caves. Mexican onyx shows a banding like that of agate, but it is much coarser. The colors of Mexican onyx range from white to green, red, and brown. Much of this soft onyx marble is cut into gemstones, colored with an aniline dye, then set in inexpensive native silver jewelry. The stones are brittle and

not durable. Mexican onyx is also used as a decorative stone.

John C. Butler

See also Cameo; Gem (picture); Sardonyx.

Oort cloud, *oort or ohr*, is a cluster of comets, smaller objects, and perhaps even planets in the outermost region of our solar system. The Oort cloud is shaped like a slightly flattened, hollow sphere. The nearest part of the cloud is roughly 500 billion miles (800 billion kilometers) from the sun. The farthest part may be 5 trillion miles (8 trillion kilometers) from the sun. The cloud holds up to 1 trillion comets. A comet can leave the Oort cloud and enter the inner solar system when disturbed by a large gravitational force, such as the gravity of a passing star.

The Oort cloud is named for the Dutch astronomer Jan H. Oort, who in 1950 suggested that it existed. Oort based his suggestion on two characteristics of the orbits of *long-period comets*—those that take 200 years or longer to revolve once around the sun: (1) The orbits originate hundreds of billions of miles or kilometers from the sun, and (2) The orbits intersect the *ecliptic plane* at random angles. The ecliptic plane is an imaginary surface through Earth's orbit around the sun. If long-period comets intersected the plane at small angles—as do short-period comets, which complete their orbits in less than 200 years—the cloud would be disk-shaped. Short-period comets come from the Kuiper belt, a disk-shaped band of rocky objects orbiting the sun just beyond Neptune.

Oostende. See Ostend.

Ooze is a name for the deposits found on the bottom of the ocean in deep waters. One type of ooze consists of a reddish-brown mud called red clay. The other major type of ooze is made up mostly of skeletons and shells of tiny sea organisms called foraminifera, radiolaria, and diatoms. All three are termed plankton, which is the name for forms of life that float in the water and drift with currents. The foraminifera make their shells from calcium carbonate that is contained in solution in the seawater. A type of limestone called nummulitic limestone is made up mostly of the discarded shells. The skeletons of the radiolaria and diatoms are usually composed of silicon.

The term ooze is also used for any mud that has a high water content. Such mud may be deposited either on the surface of the earth, or in the beds of rivers, streams, ponds, or lakes.

Opal, *OH puhl*, is a gemstone that contains a rainbow of colors. It is made up of silicon and oxygen, the elements found in common sand. The background colors of an opal may be black, blue, brown, gray, or white. Opals show brilliant colors when turned in a bright light.

The most prized opals are called black opals. These opals have a black, blue, or gray background. High quality black opals are found in New South Wales, Australia. These opals are highlighted by brilliant flashes of reds and golds and in addition to flashes of greens and blues.

Opals are unique among gemstones because of their unusual internal structure. This structure consists of numerous tiny spheres of silica that are packed together in a regular pattern to form layers. The refraction of light between these layers causes the light to break up into the colors of the rainbow, thus producing the
gemstone's extraordinary flashes of color. Opals may be found in irregular patches, often filling cavities and cracks in rocks.

In some opals, the water dries up and the opal becomes covered with tiny cracks. This process is called crazing, and it detracts from the value of the stone. Opals also are not as hard as most gems, and they may easily be scratched or chipped.

There are many different kinds of opals. Opals that display brilliant color flashes are precious opals. Most precious opals are mined in Australia. Mexico is known for its water opals and fire opals. Water opals are colorless and transparent and give off bright flashes of color. Fire opals are orange or red, and most do not give off color flashes. Opals that do not show color flashes are called common opals and are usually not considered gem material.

Because the beauty of opals lies in their internal color flashes, they are rarely cut with facets as diamonds are. Instead, they are cut with a gently rounded surface. This style of cutting is called cabochoon cutting.

Large opals of the world include a Hungarian opal that weighs 594 grams, now in the Museum of Natural History in Vienna. The Roebling opal, which was found in Nevada, is the most beautiful American opal. It is almost pitch-black, with color flashes of great brilliance. It weighs 530 grams and is on display at the National Museum of Natural History in Washington, D.C. The huge Desert Flame of A'damooka opal weighed over 6,800 grams when found in Australia in 1969. The opal is one of the birthstones for October. Robert L. Galt

Oparin, Alexander Ivanovich (1894-1980), was a Soviet biochemist. His theory of how life on earth originated from chemical substances became the basis of many later scientific ideas about the origin of life. Oparin also conducted research on the chemical conversion of raw agricultural crops into such products as bread, sugar, and wine.

Oparin's theory of the origin of life rests on his assumption that the mixture of gases in the earth's early atmosphere was much different from that of today's atmosphere. The present atmosphere is about 99 percent oxygen and nitrogen. In Oparin's view, the early atmosphere was mostly ammonia, hydrogen, and methane. These gases are composed of simple molecules.

Large amounts of these gases would have dissolved in the oceans and would have received energy from sunlight, lightning, and the earth's internal heat. Oparin suggested how this energy could have caused the simple molecules to combine into more complex molecules and how the complex molecules could have formed larger and larger combinations. After several hundred million years, such combinations could have formed the first living cells.

Oparin was born near Moscow. He graduated from Moscow State University in 1917. He first published his theory in 1924 and expanded it into a book called The Origin of Life on Earth (1936). From 1946 to 1980, Oparin headed the Bakh Institute of Biochemistry in Moscow.

Open-Door Policy is a term used in international relations. It means that powerful countries have equal opportunities to trade with colonial or developing countries. When countries agree to observe the Open-Door Policy in an area, they simply agree to permit their merchants and investors to trade freely there.

John Hay, United States secretary of state, started the idea of the Open Door in 1899. At that time, several Western powers had special interests in China. Each power was trying to get all the trading rights for itself. Hay sent notes to the competing powers, asking them to maintain complete equality for all nations that wished to trade with China. The competing powers accepted Hay's proposal, and they signed treaties agreeing to observe the Open-Door Policy. Robert J. Pranger

Open housing refers to the belief that people have a right to live wherever they choose and can afford to live. The United States government and many local and state governments have passed laws and regulations to protect this right. The laws prohibit discrimination in the sale and rental of housing on the basis of race, religion, disability, family status, or nationality. Open housing laws are sometimes called fair housing laws or open occupancy laws.

The U.S. Civil Rights Act of 1968 included the first national open housing legislation of the 1900's. The act prohibits discrimination in the sale or rental of most of the housing in the United States. It applies to all housing except (1) owner-occupied dwellings of four or fewer units, such as boarding houses; and (2) single-family houses sold or rented without the aid of a broker or real estate agent.

In June 1968, the Supreme Court of the United States went beyond the 1968 act. It ruled that a federal law passed in 1866 prohibits discrimination in the sale and rental of all property. In 1988, Congress passed a law that protected disabled people and families with children from discrimination in the sale and rental of housing. However, the fair housing laws are weakly enforced in the United States, and discrimination against African Americans and other minority groups in the housing marketplace is still common. Joe R. Feagin

Open shop is a business that employs both union and nonunion workers. It is the opposite of a closed shop, where only union members may be employed. In one use of the term, a union may represent the workers in an open shop if a majority of them belong to the union. But no one must be required to belong to the union in order to be hired. The term may also refer to a company in which the employer does not deal with a union. See also Closed shop.

Elaborate scenery and colorful crowd scenes add excitement to many operas. The spectacular "Triumphal March" shown above takes place in Act II of Giuseppe Verdi's tragic opera Aida.

**Opera**

*Opera* is a drama in which the characters sing, rather than speak, all or most of their lines. Opera is one of the more complex of all art forms. It combines acting, singing, orchestral music, costumes, scenery, and often ballet or some other form of dance.

In telling a story, opera uses the enormous power of music to communicate feeling and to express emotions. Singers, accompanied by an orchestra, may bring a dramatic situation to life more vividly than actors with spoken dialogue. Vocal and orchestral music can also tell an audience much about a character and his or her state of mind.

Because music expresses emotions so forcefully, most opera composers base their works on highly emotional stories. An opera, more than a spoken play, is likely to emphasize passionate scenes of anger, cruelty, jealousy, joy, love, revenge, sadness, or triumph. Music can also add excitement to scenes portraying spectacle. Some of the most stirring music in opera accompanies colorful crowd scenes, such as a coronation or a military parade.

Opera differs in several ways from other kinds of plays that have music. For example, William Shake-
some modern ones, have rows of boxes arranged in the auditorium. Originally, the boxes were owned by the nobility who patronized the opera and were occupied by their families and guests. Because it is difficult to get a good view of the stage from many box seats, modern opera houses rarely feature this arrangement.

Opéra, as we know it today, began in Italy in the late 1500's. Through the years, Italian composers, singers, and conductors have played a leading role in the development of opera. By the end of the 1600's, opera had spread from Italy to other European countries. Today, opera can be enjoyed in many parts of the world.

The best-known companies in Europe include those that perform at the Teatro alla Scala (La Scala) in Milan, Italy; the Opera House in Rome; the Opéra de la Bastille and the Opéra-Comique in Paris; the Royal Opera House, Covent Garden, in London; the State Opera in Vienna; and the Festival Opera House in Bayreuth, Germany.

The most famous opera company in the United States is the Metropolitan Opera Association, which performs in New York City. The Boston Opera Company, the Lyric Opera of Chicago, the New York City Opera, and the San Francisco Opera Company are also famous. Other important American companies include the Greater Miami Opera, the Houston Grand Opera, the Seattle Opera, the San Diego Opera, and the Washington (D.C.) Opera. Every summer, the Santa Fe Opera Company performs in an outdoor theater in Santa Fe, N.M.

Opening night at the opera ranks as one of the most glamorous social events of the year. The opening-night crowd below mingles in the lobby of the Metropolitan Opera House.

**Terms used in opera**

**Aria**, *AH reh uh*, is a vocal solo that usually expresses a character's feelings.

**Bel canto** refers to a style of singing that emphasizes beautiful tone and technical skill.

**Coloratura** is a flowery, ornamental vocal style generally used by soprano voices.

**Ensemble**, *ahn sahm buhl*, is a small group of singers, usually from two to five. The music the group sings is also called an ensemble.

**Grand opera** refers to operas of the mid-1800's that emphasized spectacular stage effects, big crowd scenes, and complicated, elaborate vocal and instrumental music. The term grand opera also means an opera with no spoken dialogue.

**Leitmotif**, *liht mahs tief*, is a short musical passage that identifies certain ideas, places, and characters each time they appear in the drama.

**Libretto** is the text of an opera.

**Opera buffa**, *boof lah*, is an Italian comic opera that deals with humorous situations and characters from everyday life.

**Opera seria**, *suh reh ah*, was the leading opera form of the 1700's. It dealt primarily with historical themes from ancient times and stressed brilliant singing.

**Recitative**, *reh sigh tay tuh TEEV*, is a part of the text that provides information about the action and moves the plot forward. It is sung in a rapid, speechlike style, sometimes to orchestral accompaniment. In simple recitative, the accompaniment is provided by only a harpsichord or a harpsichord and cello or other bass instrument.

**Score** is the written or printed music for an opera, used by the conductor.

**Singspiel**, *ziehn shpeel*, is a form of German opera, usually comic, that has spoken dialogue instead of recitative. Most of the songs are simple and folklike.

**Verismo**, *vair EHSH moh*, is a style of realistic Italian opera that focuses on violent actions and emotions.

**The elements of opera**

An opera has two basic elements: (1) the libretto and (2) the music. The libretto, which means *little book* in Italian, consists of the words, or text, of an opera. The music, which is also called the *score*, consists of both vocal and instrumental music. To translate the libretto and music into a performance, an opera must have singers, a conductor, and an orchestra.

**The libretto**

To enjoy an opera fully, an operagoer should read the libretto or a summary of the action beforehand. It is especially important to read a translation of the libretto or a summary if an opera is sung in an unfamiliar language. Some public libraries have librettos. Most of them have books that contain summaries of the action in individual operas. Generally, an opera house provides a program that has a summary of the plot. Most American opera houses provide translations on a screen above the stage.

The libretto of most operas is shorter than the text of a spoken play because it takes longer to sing a given number of words than to speak them. Librettos may also be shorter than the script of a spoken play because a few measures of music can often express emotions more vividly than many lines of spoken dialogue can. Because a libretto has to be relatively short, the story of an opera is likely to be simpler than that of a spoken...
play, with fewer characters and fewer secondary plots.

Many operas have been criticized for their poor librettos. Such operas give the impression that the composer used the text merely as an excuse for the music. Many people do attend the opera mainly to hear beautiful music sung by beautiful voices. Other people, however, feel that a good opera must also be a good drama. And in fact, some librettos are excellent works of literature. These librettos include those that the Austrian poet Hugo von Hofmannsthal wrote for the operas of Richard Strauss.

The definition of good drama in opera has changed over the years. Numerous subjects that were popular in operas of the 1600s, 1700s, or 1800s are now out of fashion. Yet modern opera-goers can still enjoy these older operas if they learn something about the customs in drama and music that influenced their composition.

**Recitative and arias.** Certain parts of the libretto simply provide information for the audience. For example, one character may tell another about something that has happened. In some operas, including nearly all Italian operas, the characters speak these portions of the text. But in many operas, the characters sing them in a simple, speechlike style called recitative. Most recitatives are written in everyday language—that is, they do not rhyme. Recitatives were especially popular in operas of the 1700s and early 1800s.

The most emotional parts of the libretto are solo numbers called arias. They usually express a character’s feelings or thoughts. Most arias are written in rhetorical, rhymed verse. They are also set to far more elaborately music than are recitatives. In fact, arias provide the most beautiful and dramatic music in many operas.

Spoken dialogue or recitative carries the action forward. At intervals, the action stops and the characters sing arias to express their feelings. An example of the use of recitative and aria appears in the following passage from Wolfgang Amadeus Mozart’s opera *Don Giovanni*. In the passage, a character sings several lines of recitative, ending with:

> Every means must be sought to discover the truth . . . I shall avenge her!

He then sings an aria that begins with these lines:

> My peace depends on hers; that which pleases her gives life to me . . .

The recitative above tells the audience about the character’s future actions. The aria expresses his state of mind. The original Italian text for this aria was written in rhymed poetry.

**Ensembles.** In many operas, the libretto calls for two or more singers to engage in a musical dialogue, called an ensemble. The singers themselves are also called an ensemble. The most common ensembles are duets, trios, quartets, and quintets.

Some ensembles require several characters to sing at the same time and express their thoughts and feelings. They may sing the same words, showing agreement. Or they may sing different words and melodies, expressing conflicting feelings and thoughts.

**The music.**

**The singers.** In an opera, each role calls for a singer with a specific voice range. Opera singers are therefore classified according to the range of their voices.

The basic vocal classifications for women, from highest to lowest range, are soprano, mezzo-soprano, and contralto. Each of these classifications can be divided into more specialized groups. For example, sopranos can be divided into coloratura sopranos, lyric sopranos, and dramatic sopranos. Coloratura sopranos have a very high range and can sing with great agility. Lyric sopranos have a light, graceful voice appropriate to youthful roles. Dramatic sopranos have a rich, strong voice suited to highly emotional parts.

The chief voice classifications for men, from highest to lowest range, are tenor, baritone, and bass. Each classification can be divided into more specialized groups. For example, tenors can be divided into lyric tenors and dramatic, or heroic, tenors. A lyric tenor has a light, high voice. A dramatic tenor, often called the German word Heldentenor, has a rich, powerful voice with a lower range than a lyric tenor. Such voices are needed for the heroic roles in operas by Richard Wagner. Bass voices are classified as basso cantante, basso buffo, or basso profundo. A basso cantante has the highest bass voice, with a character similar to that of a lyric tenor. A basso buffo has a deep, flexible voice and sings comic roles. A basso profundo has an especially low voice and usually sings majestic, serious roles.

**Choral singing.** Most operas include choral singing as well as arias, recitatives, and ensembles. The function and importance of the chorus vary from opera to opera and even within an opera. A chorus may provide only visual background for a scene. For example, it might portray a crowd at a festival. Or a chorus may be required merely to shout an exclamation, such as "Hail to our great king! But in some works, the chorus plays a leading part in the story and sings complicated music.
An opera chorus is a large group of singers who perform as a unit. Members must be able to act expressively while they sing. The chorus above portrays an excited crowd outside a bull ring in a scene from Act IV of Carmen by Georges Bizet.

**Acting in opera.** For a successful career in opera, a singer must have acting skill in addition to an outstanding voice. Most young singers who plan a career in opera take several years of acting lessons.

Opera acting presents special problems because it is difficult to act and sing at the same time. Sudden movements, walking, running, and twisted body positions may all interfere with the production of a beautiful, clear, and steady tone. For this reason, opera acting tends to be less lively and less realistic than acting in other forms of drama.

**The conductor** plays a key role in opera. Throughout a performance, the conductor must keep the singers and orchestra together. The beat must be clearly seen by singers far from the conductor and by musicians sitting in the dim light at the ends of the orchestra pit. Although the conductor sets the tempo, he or she must be able to react to unexpected circumstances. If a soloist begins to sing faster, for example, the conductor may have to adjust the orchestra's tempo. Because of all these special demands, opera conducting requires greater skills than does any other kind of conducting.

Some operas call for scenes in which musicians and singers perform onstage. In such instances, an assistant conductor directs the offstage music. In some modern opera houses, the assistant conductor directs the offstage music while following the conductor's beat over closed-circuit television.

**The orchestra.** The number and kinds of instruments in the orchestra depend on the opera being performed. The instruments needed for Italian operas composed in the late 1700s differ greatly from those needed for operas written by Wagner in the late 1800s.

The particular opera being performed also determines the orchestra's function. In most operas, the orchestra's basic job is to accompany the singers. The accompaniment may be simple, providing only enough harmonic and rhythmic background to keep the singers on pitch and in time. But the orchestra may also serve a more important role. For example, it might play music that introduces the general emotional quality of an aria before a note has been sung. The orchestra may even emphasize a passage in the text. For example, a heavily rhythmic beat might accompany the words "my heart pounds faster."

In some scenes, one or more characters may be alone a long time without singing or speaking. During that period, the orchestral music expresses their feelings. This kind of characterization through music is one of the strengths of opera and is impossible in spoken plays.

In many operas, the orchestra often repeats a melody or short theme from an earlier scene. This melody or theme, without singing or spoken words, is called a leitmotif. Composers repeat the leitmotif to remind listeners of some action, character, or idea previously introduced in the opera. Composers of the 1800s, notably Wagner, used the leitmotif most effectively.

Pieces of orchestral music called interludes are used to connect scenes. Interludes provide time for scenery changes or for new characters to enter. Interludes also may indicate shifts in the emotional atmosphere in an opera. Occasionally, orchestral music imitates the sounds of nature. In Wagner's Siegfried, the orchestra imitates the sounds in a forest.

Most operas begin with an orchestral overture. Some overtures merely indicate that the performance is about to begin. But others have a more important function. Some introduce the opera's principal melodies. Others set the mood for the opening scene or for the opera in general. In some older operas, the overture is uncomplicated and brief. A number of overtures of the 1800s are elaborate pieces that run 10 minutes or longer.

Musicians occasionally perform onstage in costume and participate in the action of the opera. For example, musicians may take part in such onstage activities as a military parade or a religious procession.
An opera company produces several operas in a season. In selecting each work for production, the company must consider several factors. These factors include the estimated cost of presenting the opera and whether the work will attract a large audience. Most opera companies attempt to balance their season with both comic and tragic operas. They also try to select works by a variety of composers and from different historical periods.

The people behind the scenes

During an opera performance, the audience sees only the conductor, orchestra, and performers. But an opera production also requires the skills of many other people. These people include (1) the general manager, (2) the stage director, (3) costume and set designers, (4) the members of the technical staff, and (5) the stage manager. All these specialists perform about the same work for an opera as they would for a spoken play. But opera requires that they coordinate all parts of the production with the music.

The general manager supervises the overall artistic and business policy of the opera company. This person plays a major part in choosing the repertoire and in hiring singers, conductors, and stage managers. The general manager follows each production through the planning and rehearsal stages to make sure it is progressing satisfactorily. Some companies have a music director or artistic director who controls the hiring of singers and conductors.

The stage director is responsible for the visual aspects of an opera production, just as the conductor is responsible for the music. The stage director must coordinate every action on the stage with the music. The director helps singers interpret their roles, works with the designers on ideas for costumes and sets, and helps determine the lighting. See Theater (The director).

The stage director faces one of the greatest challenges in handling choral scenes. The chorus should not simply stand still and look at the conductor while singing. All dramatic illusion would be lost. The director must assign all members of the chorus some activity so they will appear natural on the stage. Some operas have scenes in which the chorus takes part in vigorous action while singing. One such scene takes place near the end of Act II of Wagner's opera *The Mastersingers of Nuremberg*. A riot breaks out among a crowd of angry townspeople played by the chorus. In such scenes, the chorus must act convincingly while singing and following the conductor. The stage director has to plan choral scenes like these carefully and then rehearse the scenes frequently.

Sometimes, a stage director may create a new interpretation of an opera. Because the repertoire of opera companies consists chiefly of a dozen works performed repeatedly, audiences may welcome a production that presents a familiar opera in a fresh way. But some directors have been criticized for taking too many liberties with an opera, for example, by setting it in a different historical period.

The designers. The story of most operas in the standard repertoire takes place before the 1900s. Therefore, the costume and set designers must generally research the particular period of the story so their designs accurately reflect the time and place of the action. In Giuseppe Verdi’s *Aida*, for example, the costumes and sets should realistically portray ancient Egypt.

The costumes and sets should be designed so that the performers can move about freely. In addition, the set designer always has to consider the requirements of the music. For example, the music may allow a singer a certain amount of time to move from a door to a table and begin an aria. The designer must arrange the set so the singer can move naturally and still arrive at the table at the precise moment in the music when the aria be-

The set designer makes a scale model of a set, foreground, to determine how the scenery will look on the full stage. The workers in the background are painting a large backdrop for a set.

The costume designer creates costumes suitable to an opera’s time and place. These designers fit a singer with a gown for Jules Massenet’s *Manon*, which is set in the 1720’s in France.
Opera rehearsals involve both technicians and performers. At a lighting rehearsal, left, an electrician in a lighting booth works with the director onstage to create desired lighting effects. The director also rehearses the singers, right, to develop stage movements and interpretations of roles.

gins. The set designer may also have to plan the sets to provide space for large choral or dance scenes. See Theater (Scene design; Costumes and makeup).

The technical staff. Many technicians work with the stage director in planning and carrying out the visual aspects of the production. The electricians are especially important members of the technical staff. They operate the complicated lighting equipment that is used to illuminate parts or all of the stage and to provide atmosphere. Some stage directors rely on lighting, rather than on realistic sets, to express an opera's mood. See Theater (Lighting and sound).

During an opera performance, the various crews of technicians and stagehands must work quickly, quietly, and efficiently backstage. One crew changes the scenery between acts or scenes. Another crew adds the small
objects, called *props*, that the performers use in the action. A third crew sets up and adjusts the lights. For changing scenery, some opera houses use revolving stages or stages that can be raised or lowered by elevator. Special technicians operate the machinery that moves these stages. See *Theater* (Changing scenery).

**The stage manager** has charge of all backstage activity during a performance. He or she must see that all the props needed for a scene are on the stage and in the correct place. The stage manager calls the performers from their dressing rooms at specific times so they can make their entrances on schedule. The stage manager also gives the electricians cues to change the lighting during the performance.

**Preparation of a production**

**Planning a production.** After a company selects an opera, the general manager and the management staff establish the production's budget. They also choose the cast and assign a stage director and conductor to the production. Most companies employ a resident group of singers, conductors, and directors for an entire season. However, nearly all companies also hire guest singers to take the leading roles for a single production. In addition, companies frequently use guest conductors, stage directors, and designers.

In some cases, the most important consideration in selecting an opera is whether a company can hire a particular guest singer. Sometimes a company wants a certain singer so much it will let the artist choose the opera. In casting the leading parts, the opera company first of all seeks singers who have outstanding voices. But the performers should also act well and, preferably, have the physical appearance suited to the characters they are to portray.

During the early stages of a production, the key personnel hold many conferences. The stage director, for example, meets frequently with the costume and set designers. Sketches of the designs must be approved early to allow enough time for the costumes and sets to be made. The costumes and sets may be manufactured in the opera house workshops or by outside firms. Sometimes, sets and costumes are borrowed or rented from another opera company.

**Rehearsing a production.** After many months of planning the production, rehearsals begin. At first, the singers, chorus, and orchestra rehearse separately in rehearsal rooms. If the opera calls for dancing, the dancers also practice by themselves.

The stage director rehearses the principal singers to work out stage movements and establish interpretations of the roles. The chorus rehearses under the direction of a chorus master. A *choreographer* (dance creator) supervises dance rehearsals. The conductor and the conductor's assistants rehearse the orchestra.

A few weeks before the opera is to open, rehearsals move from separate facilities to the main stage. These rehearsals take place with piano accompaniment only.

Meanwhile, the stage director and the chief electrician hold lighting rehearsals. In most operas, directors use elaborate lighting that is changed frequently during the performance. Lighting rehearsals develop the best ways to achieve desired effects. The rehearsals also set the timing for the various lighting changes.

As the opening nears, the orchestra rehearses with the entire cast on the main stage. Because of the central function of the music, the conductor takes charge of these rehearsals.

A few days before opening night, the performers and orchestra stage a dress rehearsal. A dress rehearsal is presented like an actual performance, with costumes, makeup, and sets. By this time, the production should move with split-second timing. The music sets the pace for the action and should not have to be sped up or slowed down to adjust to what happens onstage.

**Offstage music** is required in some operas. An assistant conductor leads the musicians and singers hidden in the wings. He conducts from a score while following the lead of the conductor in the orchestra pit over closed-circuit television.
The first operas were composed and performed in the 1590's in Florence, Italy. There, a group of noblemen, musicians, and poets had become interested in the culture of ancient Greece, especially Greek drama. This group, called the Camerata, believed that the Greeks sang rather than spoke their tragedies. The Camerata attempted to re-create the style of ancient Greek tragedy in music. They took most of their subjects from Greek and Roman history and mythology. The Camerata called their compositions *dramma per musica* (drama for music) or *opera in musica* (musical work). The term *opera* comes from the shortened form of opera in musica. Jacopo Peri, a member of the Camerata, composed what is generally considered to be the first opera, *La Dafne* (1597).

**Baroque opera**

Opera emerged as an art form in western Europe during the baroque period in music history. This period began about 1600 and ended about 1750. Baroque music was elaborate and emotional. Italians composed the earliest baroque operas, and Italian-style opera dominated most of the period.

**Early baroque opera.** The first baroque operas consisted of recitatives, sung by soloists, and choral passages. A small orchestra accompanied the singers.

During the 1600's, the aria gradually emerged and developed as a separate function from that of the recitative. The recitative served to carry the plot of the opera forward. The arias became pauses in the action in which characters expressed their thoughts and feelings. Singers often used arias for showing off their vocal skills rather than for dramatic expression. A very common form of presentation called *simple recitative* developed in the 1600's. In it, the singers were accompanied by only a harpsichord—or by a harpsichord and cello or other bass instrument—rather than by the full orchestra.

Claudio Monteverdi, the first great composer of baroque opera, wrote the first opera masterpiece, *Orfeo* (1607). Later Monteverdi worked in Venice and made it the center of opera during the early 1600's. The world's first public opera house, the Teatro San Cassiano, opened in Venice in 1637.

By the late 1600's, operas were being written and performed in a number of European countries outside Italy, especially in England, France, and Germany. Italian opera was the accepted style, and many non-Italian composers wrote operas in the Italian manner and to Italian librettos.

**Opera seria and opera buffa.** Italian opera of the early 1700's developed into two basic types—(1) *opera seria* (serious opera) and (2) *opera buffa* (comic opera). Both types consisted of a succession of recitatives and arias.

**Opera seria.** Composers of opera seria based their works on stories of ancient heroes and heroines. In the 1600's, similar stories had included both comic and serious characters. They had provided spectacular stage effects, such as earthquakes and floods and big coronation or battle scenes. But comic scenes and spectacle were eliminated from serious opera in the 1700's. Emphasis fell instead on the skills of the principal singers. By the 1800's, many singers were trained in a vocal style called *bel canto*, which emphasized technical skill and beauty of tone. The *da capo* aria became a major feature of opera seria. It had three parts, the third being a repetition of the first. In the repeated part, the singer was expected to add difficult passages and other ornamentation not included in the score.

**Opera buffa** began as comic skits, called *intermezzi*, performed in front of the curtain between the acts of an opera seria. The characters in opera buffa were common people, unlike the characters in opera seria. Characters in opera buffa represented the professions and

---

*Opera in Italy* during the 1600's called for spectacular scenery and often dealt with ancient heroes and heroines. The Italian designer Alfonso Parigi created the elaborate set at the left for an opera seria. It shows the workshop of Vulcan, the blacksmith to the gods in Roman mythology. Parigi designed the workshop as a cave at the foot of several towering cliffs.
social classes of the time, including doctors, farmers, merchants, servants, and soldiers. The typical opera buffa dealt with humorous situations from everyday life. Many characters in opera buffa sang in dialects (local forms) of Italian rather than the formal Italian of opera seria. A very successful intermezzo was *La serva padrona* (1733) by Giovanni Pergolesi.

Italian opera seria and opera buffa were extremely popular. Hundreds of them were written, often in a short time. Most of these works were performed for one season and then forgotten. Because of the constant demand for new operas, composers used the same librettos over and over again. By today's standards, many librettos had unconvincing plots and unbelievable characters. Although some operagoers complained about the weak librettos of many Italian operas, most audiences of the 1600's and early 1700's enjoyed the works, chiefly for their music.

**French opera.** A distinctly French style of opera appeared in the 1670's. Before that time, the French showed little interest in opera. The few operas performed in the country were written in the Italian style. Jean-Baptiste Lully, though born in Italy, established a French form of opera. In the mid-1700's, Jean-Philippe Rameau became the leading composer of French opera.

French opera composers avoided the rapid recitatives and showy arias of Italian opera. Instead they preferred expressive melodies or simple songs. The recitatives were accompanied by a full orchestra and closely followed the rhythms of the French language. Ballet played an important part in French opera during the baroque period, as well as later.

In France, royalty became the chief patrons of opera. Lully acquired his fame at the court of King Louis XIV. The nobility in France and other countries competed with one another in maintaining large opera companies. To impress audiences with their wealth, the nobility sponsored productions noted for expensive scenic effects, such as gods riding chariots in the sky.

**Classical opera.**

Dissatisfaction with Italian opera began to spread among operagoers during the mid-1700's. Attacks centered on the increasingly long and dramatically weak arias, which served only to glorify the singers. The reaction against Italian opera led to a series of reforms early in the classical period. The classical period began about 1750 and lasted about 70 years. The first important classical opera composer was Christoph Willibald Gluck, a German. The greatest classical composer was Wolfgang Amadeus Mozart, an Austrian.

**Gluck and opera reform.** Gluck believed drama and music should be unified in opera. By integrating the music with the story in *Orpheus and Euridyce* (1762) and other works, he put his beliefs into practice. Gluck rejected improbable plots and emphasis on showy arias. In his operas, the music served the story. Gluck simplified the action to make the stories and characters appear more natural. He also was one of the first composers to supervise all aspects of a production.

**Mozart,** like Gluck, felt that the music in an opera should help make the story and characters believable. Mozart achieved this goal by carefully relating the instrumental and vocal music to the action. He showed particular skill in using music to create characterization—that is, to develop the personality of the characters. Mozart did this in ensemble scenes and in arias.

Mozart composed operas in both Italian and German. His best-known Italian operas are *The Marriage of Figaro* (1786), *Don Giovanni* (1787), and *Così Fan Tutte* (1790). His notable German operas include *The Abduction from the Seraglio* (1782) and *The Magic Flute* (1791). Both of these works contain elements of Singspiel (song play). Singspiel is a form of German opera that has spoken dialogue rather than recitative. Most stories are comic. The melodies often are simple and resemble the style of German folk and popular songs.

**Opera in the 1800's.**

**Romanticism** was a movement from the late 1700's to the mid-1800's that emphasized emotionalism in the arts, including opera. The typical romantic opera had a setting in nature, a theme based on folklore or the supernatural, and colorful music. Carl Maria von Weber, a German, wrote one of the earliest and greatest romantic operas, *Der Freischiitz* (1821). The story is set in Germany's Black Forest, and most of the chief characters are simple countryside people. The orchestra has an important part in portraying many of the sounds of nature as well as supernatural forces.

Several Italians also created a romantic style of opera. The most successful of these composers were Vincenzo Bellini and Gaetano Donizetti. Many of their operas require voices trained in the bel canto style.

**Grand opera** became popular in the early 1800's, especially in France. Composers of grand opera favored heroic episodes from history, in which they could use crowd scenes, spectacular stage effects, and complicated and elaborate vocal and instrumental music. Giacomo Meyerbeer, a German, became the leading composer of French grand opera with such works as *Les Huguenots* (1836) and *Le Prophète* (1849). Gioacchino Rossini, an Italian-born composer living in France, also wrote a famous grand opera, *William Tell* (1829).

**Giuseppe Verdi** dominated Italian opera during the mid- and late 1800's. He is still perhaps the most popular opera composer in history. Verdi's best-known works include *Rigoletto* (1851), *Il Trovatore* (1853), *La Traviata* (1853), and *Aida* (1871). All are noted for their emotional power, which is expressed through eloquent vocal music. *Aida* is also an example of grand opera.

Verdi wrote his last two operas—*Otello* (1887) and *Falstaff* (1893)—when he was in his 70's. Both works demonstrate that old age did not diminish but rather refined his genius. The operas are masterpieces of characterization through music, and they show complete fluidity of vocal and instrumental writing.

**Richard Wagner** was the most important German opera composer of the 1800's. Wagner believed that all the parts of an opera production—acting, costumes, drama, orchestral music, singing, and staging—should have equal value. He wrote his own librettos and, whenever possible, supervised the staging of a production. Wagner departed from tradition by making the orches-
tria as important as the singers. In many of Wagner's late works, instruments perform the main melodies.

As a young man, Wagner was greatly impressed by Weber's romantic opera *Der Freischütz*. The *Flying Dutchman* (1843), one of Wagner's early works, shows similar romantic qualities. These qualities include the supernatural aspects of the plot and the musical representation of the forces of nature, such as the wind and the sea. In *The Flying Dutchman*, Wagner first used musical themes to identify certain characters, places, or ideas each time they appear in the drama. Wagner expanded this *leitmotiv* technique greatly in his later operas. *Tristan and Isolde* (1865) and the four works called *The Ring of the Nibelung* (1876) represent Wagner's fully developed personal style.

**Nationalism** influenced many composers throughout Europe during the 1800s. These composers based much of their work on the folk music of their nation or region. Czech nationalism, for example, dominates the operas of Antonín Dvořák and Bedřich Smetana. *The Bartered Bride* (1866) by Smetana and *Rusalka* (1901) by Dvořák are outstanding examples of nationalistic operas. Russian composers of nationalistic operas include Modest Mussorgsky with *Boris Godunov* (1874) and Alexander Borodin with *Prince Igor* (1890).

**Verismo opera.** In the late 1800s, some Italian composers began to write grimly realistic operas. These *verismo* (meaning true or realistic) operas focused on violent emotions and actions. The earliest and best-known verismo operas are *Cavalleria Rusticana* (1890) by Pietro Mascagni and *Pagliacci* (1892) by Ruggiero Leoncavallo, both one-act works usually performed together.

**The 1900's**

**Giacomo Puccini** was the most popular Italian opera composer of the early 1900s. His operas are noted for their melodic and sometimes sentimental music and for their theatrically effective librettos. Puccini first gained widespread attention in the 1890s with *Manon Lescaut* (1893) and *La Bohème* (1896). He followed these works with *Tosca* (1900), a verismo opera. His other notable operas include *Madama Butterfly* (1904) and *Turandot* (produced in 1926, after his death).

**Richard Strauss** became the most important and successful German opera composer after Wagner. Strauss wrote operas that require singers with great vocal power. He is best known for three early operas—*Salome* (1905), *Elektra* (1909), and *Der Rosenkavalier* (1911). *Salome* and *Elektra* originally caused much controversy among operagoers because of their brutal action and harsh music. *Der Rosenkavalier*, however, is entirely different in mood and theme. In this opera, Strauss and the librettist, Hugo von Hofmannsthal, created an affectionate portrait of aristocratic society in Vienna in the 1700s.

**The search for new forms.** After World War I (1914-1918), many composers began to search for new forms of operatic expression. Some composers included ele-
mots of American jazz in their operas. Ernst Křenek, an Austrian, used jazz in his opera Jonny spielt auf (1927). The German composer Kurt Weill wrote The Threepenny Opera (1928) in the style of the music heard in German cabarets (nightclubs).

Meanwhile, a movement called Expressionism had developed in the arts. Expressionism aimed at exploring the subconscious and became especially important in drama and painting. But Expressionist qualities also appeared in several operas. Such operas had a brooding, nightmarish atmosphere, reinforced by dissonant music and symbolic and violent actions.

Straus's Salome was an early example of the Expressionist style. But Alban Berg, an Austrian composer, ranks as the leading opera composer in the movement. Berg wrote Wozzeck (1925), the most successful Expressionist opera. Other operas related to Expressionism include Duke Bluebeard's Castle (completed 1911, first performed 1918) by the Hungarian composer Béla Bartók and From the House of the Dead (1930) by the Czech composer Leos Janáček.

Some of the most successful and theatrically effective operas of the 1900's were written by the British composer Benjamin Britten. His opera Peter Grimes (1945) is a brooding but lyrical portrait of social alienation.

American opera. American composers wrote no important operas until the 1900's. George Gershwin wrote a highly original and popular American opera, Porgy and Bess (1935). The work describes life among blacks in Charleston, South Carolina, in the 1920's. Porgy and Bess has been acclaimed worldwide as a genuine American folk opera.

The most successful opera composer in the United States is Gian Carlo Menotti. He composes in a traditional style that shows the influence of Puccini. Menotti wrote an opera for radio, The Old Maid and the Thief (1939), and an opera for television, Amahl and the Night

Visitors (1951). His best-known stage operas include two tense dramas, The Medium (1946) and The Consul (1950).

Since World War II (1939-1945), the best operas have been written by more tradition-minded composers. They include Douglas Moore's folk-inspired The Ballad of Baby Doe (1956) and Virgil Thomson's The Mother of Us All (1947). The text for The Mother of Us All was written by American author Gertrude Stein.

Opera has played only a minor role in modern American experimental music. Some Americans associated with the Minimalist movement have written several important operas. The Minimalist style uses repeated short patterns of music with complex rhythmic variations but simple harmonies. Operas in this style include Phillip Glass's Einstein on the Beach (1975), which draws on rock music, and John Adams's Nixon in China (1987).

Opera today

The experimentation in opera that began after World War II continues today. Some composers have explored new dramatic and musical techniques, including the use of electronic sounds, motion pictures, and color slides. Aniara (1959), a science-fiction opera by the Swedish composer Karl-Birger Blomdahl, takes place in a spaceship and uses taped and electronic sounds. Bomarzo (1967) by the Argentine composer Alberto Ginastera also features unconventional sound effects, especially in fantastic, dreamlike scenes.

Operagoers today, however, still prefer older, traditional works. Only a few operas composed since the end of World War II receive frequent productions. But many changes have occurred in the way older operas are staged. For example, stage directors often try to create desired moods through lighting effects made possible by modern lighting equipment.

Meanwhile, artistic and economic problems trouble all major opera companies. Before the development of fast, convenient air travel, leading singers remained with one company an entire season. But jet travel enables singers to appear as guest artists in many opera houses in a season. Artists earn more money as guests, and audiences can see and hear many famous singers. However, traveling artists often follow a tight, exhausting schedule that leaves too little time for rehearsal. As a result, audiences often attend performances that show a lack of adequate preparation.

The cost of producing opera has risen steadily. Even if an opera house sells every ticket for an entire season, it cannot meet expenses. Ticket sales seldom provide more than half the income needed to operate an opera company. American companies rely on contributions from individuals, corporations, and foundations to make up losses. Many European countries, cities, and states support opera with public funds. Numerous people in the United States believe the national government or local governments should help support opera and the other arts, as governments do in Europe.

Most U.S. colleges and universities have opera workshops. They provide training and experience for young singers and also present performances for the general public. Some colleges and universities have staged revivals of worthwhile but little-known works.
Opera companies today present mainly works that were composed between the late 1700s and the early 1900s. Almost all the operas in this standard repertoire were written by Austrian, French, German, Italian, and Russian composers. This section describes some of the most popular operas in the standard repertoire. Some of the recommended books that are listed at the end of this article provide more detailed discussions of the repertoire.

**Aida**, a tragic opera in four acts by Giuseppe Verdi. Libretto in Italian by Verdi and Antonio Ghislanzoni. First performed in Cairo, Egypt, in 1871.

The khedive (ruler) of Egypt asked Verdi to write Aida to help celebrate the opening of the Suez Canal and the Cairo opera house. The story takes place in ancient Egypt and concerns the tragic love affair between Aida, an Ethiopian slave, and Radames, an Egyptian military officer. Aida is grand opera and so requires a large cast. The work has impressive crowd scenes, featuring choruses of soldiers, slaves, and priests, and an elaborate ballet. In Act I, Radames expresses his love for Aida in a beautiful aria, "Celeste Aida." Act II includes the stirring "Triumphal March," in which the Egyptian king reviews his victorious army.

**Barber of Seville, The** (Il Barbiere di Siviglia), a comic opera in two acts by Gioacchino Rossini. Libretto in Italian by Cesare Sterbini, based on the French play The Barber of Seville by Pierre de Beaumarchais. First performed in Rome in 1816.

The story of The Barber of Seville takes place in Seville, Spain, in the 1600s. This work is a good example of Italian comic opera, or opera buffa. The libretto has many characters and situations typical of this style. The characters include an old man called Doctor Bartolo who is interested in a beautiful and rich young woman named Rosina. He jealously watches over her but cannot prevent a dashing young nobleman (Count Almaviva) from meeting and finally marrying her. Other traditional characters include a drunken soldier, who is really the count in disguise, and an irritable housekeeper. Figaro, the barber in the opera’s title, helps the count win Rosina.

In Act I, Rosina’s aria "Una voce poco fa" provides opportunities for brilliant singing. Also in Act I, Figaro makes his first appearance singing a popular comic aria, "Largo al factotum," in which he boasts how clever he is. The opera also has a lively overture, which Rossini had used in two earlier operas.

**Bohème, La** (*The Bohemian*), a tragic opera in four acts by Giacomo Puccini. Libretto in Italian by Giuseppe Giacosa and Luigi Illica, based on the French novel *Scenes from Bohemian Life* by Henri Murger. First performed in Turin, Italy, in 1896.

Four poor but carefree young men are living a bohemian life together in an attic in Paris about 1830. They are Rodolfo, a poet; Marcello, a painter; Schaunard, a musician; and Colline, a philosopher. Mimi, a frail young girl in poor health, is their neighbor. She and Rodolfo meet and fall in love. But at the end of the opera, Mimi dies. The main secondary plot deals with a stormy love affair between Marcello and a young woman named Musetta.

Although La Bohème ends tragically, it has many humorous and sentimental moments. The opera also has a number of Puccini’s most beloved melodies. One of these melodies is "O soave fanciulla," a love duet between Rodolfo and Mimi that ends Act I. Perhaps the opera’s most familiar melody is the aria "Musetta’s Waltz" in Act II.

**Boris Godunov**, a tragic opera in a prologue and four acts by Modest Mussorgsky. Libretto in Russian by the composer, based primarily on the Russian play *Boris Godunov* by Alexander Pushkin. First performed in St. Petersburg, Russia, in 1874.

The opera takes place in Russia and Poland from 1598 to 1605 and concerns Russian historical figures. Boris

---

*The Barber of Seville* by Gioacchino Rossini is one of the most popular comic operas. Act I ends in the wild argument shown here between Doctor Bartolo, *left center*, and Count Almaviva, *right center*, who is masquerading as a drunken soldier. Don Basilio, a music teacher, and Berta, a maid, try to hold back the doctor. Figaro, a barber, and Rosina, the count’s sweet-heart, attempt to restrain the nobleman.
La Bohème by Giacomo Puccini deals with a love affair between Rodolfo, a poet, and Mimi, a young seamstress in failing health. Near the end of Act IV, above, Rodolfo and the dying Mimi sing a beautiful love duet in the poet’s attic lodging.

Godunov, an adviser to the czar, has the czar’s young heir murdered. After the czar dies, Boris takes the throne. But in time, his feelings of guilt cause him to have visions of the murdered heir, and he finally collapses and dies. The “hero” of the opera is the Russian people, portrayed by the chorus. The chorus takes part in many scenes, including an impressive coronation.

Many musicians in Mussorgsky’s time considered the music for Boris Godunov too harsh and crude. After Mussorgsky’s death, his friend and fellow Russian composer Nikolai Rimsky-Korsakov revised the orchestration for the opera. Rimsky-Korsakov’s version is often performed today.

Carmen, a tragic opera in four acts by Georges Bizet. Libretto in French by Ludovic Halévy and Henri Meilhac, based on the French story “Carmen” by Prosper Mérimée. First performed in Paris in 1875.

The action of Carmen is set in and near Seville, Spain, about 1820. Carmen is a beautiful Gypsy dedicated to a life of unrestrained freedom. While working in a cigarette factory in Seville, she meets Don José, a soldier, and has a love affair with him. Later, she leaves Don José for Escamillo, a bullfighter. At the end of the opera, Don José pleads with Carmen to return to him. After she scornfully refuses, Don José stabs her to death in a jealous rage.

The exciting plot, colorful Spanish setting, and stirring music have made Carmen one of the most popular works in the repertoire. Many of the opera’s melodies have become almost as familiar as popular songs. They

Boris Godunov by Modest Mussorgsky is a psychological tragedy based on events in Russian history. In the prologue to the opera, above, Russian peasants in Moscow bow before Boris shortly after he has been crowned czar. Members of the Russian nobility stand behind him.
include Carmen’s dancelike arias “Habanera” and “Seguidilla” in Act I and Don José’s “Flower Song” and Escamillo’s “Toreador Song” in Act II. The opera also has rousing choral and dance numbers.

**Cavalleria rusticana** (*Rustic Chivalry*), a tragic opera in one act by Pietro Mascagni. Libretto in Italian by Guido Menasci and Giovanni Targioni-Tozzetti, based on the Italian story and play *Cavalleria rusticana* by Giovanni Verga. First performed in Rome in 1890.

Traditionally, *Cavalleria rusticana* is performed with Ruggiero Leoncavallo’s two-act opera, *Pagliacci*. The passion, realism, and violence of both works make them major examples of verismo opera.

The action in *Cavalleria rusticana* takes place in a Sicilian village in the 1800’s. There, Lola, a married woman, has a love affair with Turiddu, a young soldier. The title of the opera refers to the villagers’ code of honor. According to this code, Alfio, Lola’s husband, must seek revenge. He challenges Turiddu to a duel and kills him.

The composer and librettists used several effective dramatic devices. Halfway through the opera, the villagers are in church, and the stage is empty. During this interval, the orchestra plays the “Intermezzo.” This gentle, melodic instrumental piece provides relief from the tense, highly emotional atmosphere of the opera. In another dramatic device, Turiddu’s death takes place off-stage. The opera audience learns of the outcome of the duel through the horrified reactions of the villagers onstage.

**Don Giovanni**, a comic opera with serious elements in two acts by Wolfgang Amadeus Mozart. Libretto in Italian by Lorenzo da Ponte. First performed in Prague, Bohemia (now part of the Czech Republic), in 1787.

Mozart’s opera *Don Giovanni* has become the best-known version of the legend about Don Juan, the Spanish rogue. The action takes place in and near Seville, Spain, in the 1600’s. In the opening scene, Don Giovanni (Don Juan) flees from the home of Donna Anna after trying to seduce her, then he kills her father in a duel. Several later episodes further show Giovanni’s immoral nature. At the end of the opera, the marble statue of Donna Anna’s slain father visits Giovanni and urges him to abandon his sinful ways. Giovanni refuses. The scene is then enveloped in smoke and fire as he disappears into hell, dragged off by a chorus of demons.

The mixture of comic and serious qualities of *Don Giovanni* has always fascinated audiences. Leporello, Giovanni’s servant, provides most of the comedy. The
most serious figure is Donna Anna. In addition to many beautiful arias, Don Giovanni has highly dramatic recitatives and long, complicated ensembles. In one scene in Act I, three orchestras onstage perform three different dance numbers at the same time during a party given by Don Giovanni. While the three orchestras play, the opera orchestra in the pit accompanies the singers.

**Faust**, a tragic opera in five acts by Charles Gounod. Libretto in French by Jules Barbier and Michel Carré, based on part I of the German play Faust by Johann Wolfgang von Goethe. First performed in Paris in 1859.

The story of **Faust** takes place in Germany in the 1500s. Faust is an old philosopher who yearns for his lost youth. Mephistopheles, the Devil, appears to Faust and grants him youth. Faust, in return, agrees that after he dies, he will serve the Devil in hell. The opera centers on the love story between the now young Faust and Marguerite, a beautiful village girl. At the end of the opera, Marguerite dies and a chorus of angels escorts her to heaven. The Devil then drags Faust down to hell.

In the 1800s, the German composers Louis Spohr and Heinrich Zöllner and the Italian composer Arrigo Boito also wrote operas based on the story of Faust and his agreement with the Devil. But Gounod's version has become the most popular. The 1859 version had spoken dialogue. Gounod substituted recitative in a production first given in 1869, and that version is performed today. In Act III, Marguerite sings the beautiful "Jewel Song." The lively "Soldiers' Chorus" in Act IV is one of the best-known choral numbers in the entire repertoire.

**Lucia di Lammermoor**, a tragic opera in three acts by Gaetano Donizetti. Libretto in Italian by Salvatore Cammarano, based on the Scottish novel The Bride of Lammermoor by Sir Walter Scott. First performed in Naples, Italy, in 1835.

Donizetti wrote **Lucia di Lammermoor** in the melodramatic style typical of Italian romantic opera of the early 1800's. The story takes place in Scotland in the late 1600's. It concerns a doomed love affair between Lucia Ashton and Edgardo di Ravenswood. Enrico Ashton, Lucia's brother, wrongfully holds Edgardo's estate. To prevent Lucia and Edgardo from marrying, Enrico tricks Lucia into wedding another man. Lucia goes insane, kills her husband, and then dies. Edgardo hears of Lucia's death and stabs himself to death.

The opera has one of the most dramatic ensembles in the repertoire, the sextet "Chi mi frena." It is sung in Act II at Lucia's wedding. But the opera is probably best known for the "Mad Scene" in Act III, in which the insane Lucia sings of an imaginary wedding between herself and Edgardo. This scene is considered one of the greatest challenges for a coloratura soprano in all opera.

**Madama Butterfly**, a tragic opera in three acts by Giacomo Puccini. Libretto in Italian by Giuseppe Giacosa and Luigi Illica, based on the American play Madama Butterfly by David Belasco, from a story by John Luther Long. First performed in Milan, Italy, in 1904.

The story of **Madama Butterfly** takes place in Nagasaki, Japan, about 1900. Cio-cio-san (Madama Butterfly) is a geisha (young Japanese woman trained to entertain men) who falls in love with an American naval officer, B. F. Pinkerton. They marry in a Japanese ceremony. According to Japanese law, either the husband or the wife may cancel the marriage on a month's notice. Pinkerton must leave Japan with his ship. After he has left, the young woman gives birth to his child. Three years later, Pinkerton sends a letter saying that he has married an American. Shortly after the letter arrives, Pinkerton appears with his American wife. The brokenhearted Cio-cio-san agrees to give them the child. She then commits suicide.

Puccini tried to give **Madama Butterfly** an Oriental flavor by basing some of his score on Japanese music. He also included a passage from 'The Star-Spangled Ban-
The Magic Flute by Wolfgang Amadeus Mozart is a fairy-tale opera. Act II, the final act, ends with this scene in the sacred Temple of Wisdom, ruled by the high priest, Sarastro. Marc Chagall, the famous Russian-born modern artist, designed this set for a production at the Metropolitan Opera House.

The opera has spoken dialogue instead of recitative. Some of the music resembles simple folk songs, though several of the arias are dramatic and solemn. The Queen of the Night, Pamina’s mother, sings two arias that are showpieces for a coloratura soprano. The arias have very hard passages and high notes. The overture is often performed as a separate work in concerts.

The Magic Flute, The (Die Zauberflöte), a fairy-tale opera in two acts by Wolfgang Amadeus Mozart. Libretto in German by Emanuel Schikaneder. First performed in Vienna, Austria, in 1791.

Mozart and Schikaneder were both members of a secret society called the Masons, and much of The Magic Flute deals symbolically with Masonic beliefs and rituals. However, the opera can be enjoyed as a fairy tale about two lovers, Tamino and Pamina. The opera takes its name from a magic flute that protects Tamino from danger.

The opera's best-known aria is the exquisite "Un bel di" in Act II. In it, Cio-cio-san describes the happiness she will feel when Pinkerton returns.

Marriage of Figaro, The (Le Nozze di Figaro), a comic opera in four acts by Wolfgang Amadeus Mozart. Libretto in Italian by Lorenzo da Ponte, based on the French play The Marriage of Figaro by Pierre de Beaumarchais. First performed in Vienna in 1786.

Beaumarchais wrote The Barber of Seville before The Marriage of Figaro. Mozart selected the second play for his opera. The Italian composer Giovanni Paisiello had

Pagliacci by Ruggiero Leoncavallo is a tragedy about a company of traveling actors who stop in an Italian village to give a performance. In an aria in Act I, Canio, the leader of the company, describes the play the actors will present that night in the village.
already composed an opera based on The Barber of Seville. The same principal characters appear in both works. The plot of The Marriage of Figaro follows the action begun in The Barber of Seville. Mozart’s opera describes the problems that develop when Figaro, servant to Count Almaviva, tries to marry Susanna, Countess Almaviva’s maid. The Count wants Susanna for himself, but a final scene of multiple disguises brings him back to his wife.

Operagoers have praised The Marriage of Figaro for its vivid, realistic characters. Unlike many opera composers of the time, Mozart relied far more on ensembles than on arias to develop his characters.

Pagliacci (The Players), a tragic opera in a prologue and two acts by Ruggero Leoncavallo. Libretto in Italian by the composer. First performed in Milan, Italy, in 1892.

A short verismo opera, Pagliacci deals with life among members of a traveling company of actors in Italy in the 1860s. The story concerns the jealousy of Canio, the leader of the players. The opera opens with a prologue sung in front of the curtain by Tonio, who plays a clown. The prologue announces the theme of the drama.

Early in Act I, Canio learns that Nedda, his wife, is unfaithful. He discovers she is having a love affair, but he does not know the identity of the man. Canio sings one of the great tenor arias in all opera, “Vesti la giubba,” which expresses his tragic fate of playing a clown while his heart is breaking. During a performance of a play, Canio learns that his wife’s lover is Silvio, a peasant who lives in the village where the actors are performing. Canio then stabs Nedda and Silvio as the opera ends.

Porgy and Bess, a folk opera in three acts by George Gershwin. Libretto in English by Gershwin’s brother Ira and DuBose Heyward, based on Heyward’s novel Porgy. First performed in Boston in 1935.

Gershwin’s Porgy and Bess is one of the few American operas that has achieved worldwide fame. The opera portrays life among black people in Charleston, S.C., in the 1920s. It specifically deals with the love of the crippled Porgy for the beautiful Bess. The story is colorful and highly dramatic, and it has considerable humor. In his score, Gershwin captured the flavor of the songs sung by black people of the Southeastern United States.

The opera consists largely of individual songs and choral scenes, connected by spoken dialogue and some recitative. Some of the songs, including “Summertime,” “I Got Plenty o’ Nuttin’,” and “It Ain’t Necessarily So,” have become popular hits.

Rigoletto, a tragic opera in three acts by Giuseppe Verdi. Libretto in Italian by Francesca Maria Piave, based on the French play Le Roi s’amuse (The King Is Amused) by Victor Hugo. First performed in Venice, Italy, in 1851.

The opera tells a story of treachery and revenge in the court of an Italian nobleman, the Duke of Mantua, in the 1500s. The chief characters include the duke; Rigoletto, a hunchback who is the duke’s jester; and Gilda, Rigoletto’s daughter. Through intrigue and deceit, Rigoletto’s beloved daughter is murdered.

For Rigoletto, Verdi composed some of his most glorious melodies. In Act I, Gilda sings the beautiful aria “Caro nome,” in which she expresses her love for the duke, who is disguised as a student. In Act III, the duke sings one of the most popular arias in the repertoire, “La donna è mobile.” The aria is an ironic comment by the faithless duke on how changeable women are in their affections. The emotional and melodic quartet “Bella figlia dell’amore” is sung later in Act III.

Ring of the Nibelung, The (Der Ring des Nibelungen), a cycle of four operas by Richard Wagner. Libretto in German by the composer. The three main parts are

Der Rosenkavalier by Richard Strauss portrays life among the aristocracy in Vienna during the 1700s. Part of the story concerns a romance between Octavian, a young nobleman, and Sophie, a wealthy young girl. They meet and fall in love in this scene in Act II. Octavian, center, brings Sophie, left, a silver rose sent by Baron Ochs. The baron, a coarse, middle-aged nobleman, plans to marry Sophie.
Die Walküre (The Valkyrie, 1870); Siegfried (1876); and Die Götterdämmerung (The Twilight of the Gods, 1876). Wagner called the fourth work, Das Rheingold (The Rhine Gold, 1869), the prologue to the other three. However, it is a complete opera. All four works were first performed as a cycle at the opening of the Festival Opera House in Bayreuth, Germany, in 1876.

The four operas have a continuous plot based on ancient German and Icelandic legends. The Rhine-Maidens guard a treasure of gold on the bottom of the Rhine River. Alberich, one of a group of dwarfs called Nibelungs, steals the Rhine gold and makes a ring from it. The ring gives magic powers to whoever possesses it. After the ring is stolen from Alberich, he puts a curse on it. The ring changes owners several times during the four operas.

Many gods and goddesses take part in the action, including Wotan, their chief; and Fricka, his wife. Other important characters include Brünnhilde, one of several female warriors called Valkyries; Siegmund, a mortal son of Wotan; Siegfried, Siegmund's son; and Sieglinde, Siegmund's sister. The Ring cycle deals with the decline and downfall of the gods, brought about by their greed and lust for power as represented by the ring.

Rosenkavalier, Der (The Cavalier of the Rose), a partly comic, partly serious opera in three acts by Richard Strauss. Libretto in German by Hugo von Hofmannsthal. First performed in Dresden, Germany, in 1911. Unlike most opera texts, the libretto for Der Rosenkavalier is an outstanding work of literature. It gloriously portrays life among the aristocracy in Vienna in the 1700's. In most productions, the sets for the first two acts are spectacular, representing luxurious Viennese palaces. The work also calls for magnificent costumes.

The opera describes the love affairs of four chief characters: Princess von Werdenberg, called the Marschallin; Octavian, a young nobleman; Sophie, a beautiful girl; and Baron Ochs, a coarse and comic country nobleman. Strauss wrote the role of Octavian to be played by a female, and a mezzo-soprano sings the part.

Strauss composed many brilliant ensemble scenes for Der Rosenkavalier. One of the most impressive takes place in Act I when the Marschallin receives many visitors. The composer emphasized the light-hearted Viennese quality of the opera in a number of lively waltzes. These waltzes are sometimes performed separately in concerts.

Salome, a tragic opera in one act by Richard Strauss. Libretto in German by Hedwig Lachmann; a translation of a play in French, Salomé, by the Irish-born author Oscar Wilde. First performed in Dresden, Germany, in 1905.

Wilde based his play on the story of Salome in the New Testament, but he invented many details that shocked audiences of his time. In Wilde's play, Salome, a 15-year-old girl, is attracted to the religious prophet Jochanaan (Saint John the Baptist). After Jochanaan rejects her advances, she decides to take revenge. Salome's stepfather, King Herod, asks her to dance for him and, in return, promises her anything she wishes. Salome performs the famous 'Dance of the Seven Veils' and then asks Herod for Jochanaan's head on a silver dish. Herod, though horrified, keeps his promise and has Jochanaan beheaded. Salome kisses the head of the prophet, an act that audiences of the early 1900's considered especially objectionable.

Strauss's score captures perfectly the mood of Wilde's gruesome story. The music is often violent and harsh. At other times, it is vigorous and passionate. The orchestral music especially helps create the rich Oriental atmosphere of the opera. The role of Salome is one of the most difficult in the repertoire. The performer must not only sing extremely complicated music, but she must also act and dance well. In addition, she should look young and beautiful.

Tosca, a tragic opera in three acts by Giacomo Puccini. Libretto in Italian by Giuseppe Giacosa and Luigi Illica, based on the French play La Tosca by Victorien Sardou. First performed in Rome in 1900. The story of Tosca takes place in Rome in 1800, when the city is torn by political intrigue. The chief characters are Floria Tosca, a famous singer; Mario, a painter and Tosca's lover; and Baron Scarpia, the villainous chief of police. In the story, Cesare Angelotti, an escaped political prisoner, has fled from Scarpia. Both Tosca and Mario know Angelotti's hiding place. Much of the action concerns Scarpia's attempts to force Tosca and Mario to reveal where Angelotti is hiding. Scarpia also wants to make Tosca his mistress. Tosca kills Scarpia and then commits suicide after she watches a firing squad execute Mario.

Puccini's music powerfully expresses the passion and violence of the plot. The work also has several beautiful melodies, including Tosca's 'Vissi d'arte' in Act II and Mario's 'E lucevan le stelle' in Act III.

Traviata, La (The Wayward One), a tragic opera in three acts by Giuseppe Verdi. Libretto in Italian by Francesco Maria Piave, based on the French play The
Verdi's most memorable music. In Act II, a band of Gypsies in their mountain camp sings what is perhaps the most familiar choral number in all opera, the stirring "Anvil Chorus."

**Wozzeck**, a tragic opera in three acts by Alban Berg. Libretto in German by the composer, based on the German play Wozzeck by Georg Büchner. First performed in Berlin in 1925.

Wozzeck is a private in the Austrian army about 1830. His superiors abuse and ridicule him. Even worse, Marie, the woman he loves, deceives him with another man. Driven almost insane by jealousy, Wozzeck stabs and kills Marie. Later, he throws the knife into a pond. Finally, he drowns while searching for the knife.

Much of the text for Wozzeck is set in an intensely emotional vocal style midway between spoken dialogue and singing. This style is known by the German term *Sprechstimme* (speaking voice). Most of the music is atonal—that is, it does not fall into the traditional keys.

Although Wozzeck is difficult to sing and play, it has been performed in many countries. Some people consider the music jarring and too hard to understand. But others feel that it effectively expresses a great variety of emotions.

---

**La Traviata** by Giuseppe Verdi describes a tragic love affair between Alfredo and Violetta in France during the mid-1800's. In this scene from Act I, they meet for the first time at a party.

**Lady of the Camellias** by Alexandre Dumas the Younger. First performed in Venice, Italy, in 1853.

Although La Traviata failed dismally at its première, it has become one of the most frequently performed works in the repertoire. Verdi set the action in and near Paris in the mid-1800's. The opera shocked many people during the mid-1800's because Violetta, its heroine, leads an immoral life.

Unlike many earlier operas, La Traviata has realistic characters with complicated emotions. Their thoughts and feelings seem especially convincing because of Verdi's theatrically effective music. For example, in Act I, Violetta tries to decide whether to fall in love with Alfredo, who loves her. The music clearly reflects her indecision. In Act III, she sings one of the opera's most haunting arias, "Addio del passato," in which she bids farewell to the happy days of the past.

**Trovatore,** *Il* [The Troubadour], a tragic opera in four acts by Giuseppe Verdi. Libretto in Italian by Salvatore Cammarano, based on the Spanish play El Trouvador by Antonio García Gutiérrez. First performed in Rome in 1853.

Like most Verdi operas, *Il Trovatore* tells a gloomy and violent story filled with passion. The action takes place in Spain in the 1400's. The principal characters include Manrico, a *troubadour* (poet-musician); Leonora, a noblewoman; Azucena, a Gypsy; and the Count di Luna. Manrico and Leonora are lovers, but the count also loves Leonora. In addition, di Luna and Manrico are brothers, though only Azucena knows it. Azucena seeks revenge against the count because his father had her mother burned at the stake. By the opera's end, Leonora has committed suicide and the count has executed Manrico. After Manrico's death, Azucena tells the count he has killed his brother, and she thus has her revenge.

Despite a frequently confusing plot, *Il Trovatore* is brilliantly effective theater. The opera also has some of the opera's most remarkable arias. It is among Verdi's greatest and most popular operas.

Of the 1900's?

What is the function of a general manager in an opera company?

Additional resources
Goulding, Phil G. Ticket to the Opera. Favcett, 1996. A guide to 100 operas.

Operetta, See Surgery.
Operetta. See Persian Gulf War. Operetta is a type of musical theater that achieved its greatest popularity from the 1850's to about 1920. Unlike a typical serious opera, operetta contains spoken dialogue instead of sung dialogue and fairly simple, straight-forward songs instead of complex arias. An operetta overture is often a medley of tunes from the show rather than a separate composition, as in opera.

Operettas generally are composed in an uncomplicated and popular style. The music is easy to perform and to understand. The plots of most operettas are romantic, sentimental, or satirical. They often involve confusion over mistaken identities and have happy endings, frequently with a moral. Most operettas also feature dances and choruses.

Operettas developed from French comic opera. Several national schools of operetta developed, beginning with the French school. The first masterpieces in the form were written by Jacques Offenbach, a German-born French composer. His major works include Orpheus in the Underworld (1858), La Belle Hélène (1864), and La Périchole (1868).

The Austrian composer Franz von Suppé was the first composer of Viennese-style operettas, beginning in the 1860's. This musical style is based on dance forms, especially the waltz. The settings are also more exotic than those of French operettas.

The master of the Viennese school was Johann Strauss, Jr. His operetta Die Fledermaus (1874) is the greatest example of the school. Romantic Viennese operettas dominated the form in the early 1900's with such works as The Merry Widow (1905) by Franz Lehár.

English composers were greatly influenced by both French and Viennese operetta. By the 1870's, the team of Sir William Gilbert and Sir Arthur Sullivan had developed an English style in such humorous and satirical works as H.M.S. Pinafore (1878) and The Mikado (1885).
Operettas were extremely popular in the United States, with French, Viennese, and English works receiving numerous productions. By the 1890s, American composers began writing successful operettas. The principal composers included Reginald de Koven, Rudolf Friml, Victor Herbert, Sigmund Romberg, and John Philip Sousa.

**Ophthalmia**, *əf-thəl-mə-uh*, is a name for severe diseases affecting the eye membranes. These diseases may be caused by infections, poisons, or injuries. For example, *ophthalmia neonatorum* is an infection of the eyes of newborn babies, usually caused by the germ that causes gonorrhea. *Sympathetic ophthalmia*, a rare condition, spreads to both eyes after a serious injury to one eye and can lead to blindness if untreated. See also *Blindness (Diseases)*.

Ronald Klein

**Ophthalmology**, *əf-thəl-mə-lō-jē*, is the field of medicine involving the diagnosis and treatment of eye diseases. An *ophthalmologist* must have an M.D. degree and three to five years of specialized training in a residency program, usually in a hospital.

Most ophthalmologists limit their medical and surgical practice to the eye. They examine the eye with special equipment and check *visual acuity* (the ability of the eye to see). If a patient's visual acuity is less than normal, an ophthalmologist usually does a *refraction* to determine whether the decrease in vision can be corrected with glasses. A refraction is a check of the power of the lens and cornea of the eye relative to the size of the eye. If the patient needs glasses, the ophthalmologist usually gives the patient a prescription for them. Glasses are made by an *optician*.

If the patient's vision cannot be corrected with glasses, the ophthalmologist's examination will help detect the cause of poor vision. An ophthalmologist performs the necessary operation if an eye condition requires corrective surgery, such as the removal of *cataracts* (clouding of the lens of an eye). Ophthalmologists also may perform other types of surgery, including surgery to correct *strabismus* (cross-eye) or other muscle imbalances of the eyes, corneal transplants, and surgery to control *glaucoma* (increase in fluid pressure in the eye).

By studying the *retina* (back layer of the eye), an ophthalmologist may discover signs of diseases of other parts of the body. For example, such diseases as diabetes, AIDS, and certain forms of anemia may cause changes in the appearance of the retina.

Ronald Klein

See also *Optometry; Surgery (Surgical specialties)*.

**Ophthalmoscope**, *əf-thəl-mə-skōp*, is an optical instrument for examining the interior of the eye. Ophthalmologists and optometrists can make certain diagnoses by using the ophthalmoscope to examine abnormalities in the eye.

There are two types of ophthalmoscopes, the *direct ophthalmoscope* and the *indirect ophthalmoscope*. The direct ophthalmoscope contains a light, a prism and a mirror, and lenses. These parts are mounted in the head of the instrument, which is attached to a handle containing a battery. The prism and mirror project the light on the back of the eye. The lenses enable the examiner to focus the light to provide a clear, magnified view of the eye's interior. The indirect ophthalmoscope consists of a light worn on the examiner's head and a lens held in front of the patient's eye. This instrument enables the examiner to see a larger area than the direct ophthalmoscope does, but with lower magnification.

The ophthalmoscope was invented by a German physicist, Hermann von Helmholtz, in 1851 (see *Helmholtz, Hermann L*). Helmholtz' instrument consisted of a sandwich of three thin plates of glass mounted at a 45-degree angle on a handle. A light was placed to the side of the eye under examination. Some light passed through the glass plates, but some was reflected into the eye. The lighted inside of the eye was observed through the glass.

Ronald Klein

**Opiate**, *oh-pē-iet* or *oh-pē-it*, is any drug made from or containing opium. Opium is a dried milky substance obtained from unripened seedcases of the opium poppy plant. Morphine and codeine are opiates used for their healing properties. These drugs are *analgesics* (painkillers). Physicians prescribe them mainly for people with severe pain. Opiates also are used to help control coughing and severe diarrhea.

Continued use of opiates can reduce their healing effects and can also lead to addiction. Therefore, opiates and synthetic drugs that have the same chemical structure as opiates have been made *controlled substances* by law. This means they can be obtained lawfully only
by getting a prescription from a physician or, in some cases, by signing a register at a pharmacy. Heroin is a highly addictive opiate. Federal law totally prohibits the sale and use of heroin in the United States.

Barbara M. Bayer

**Opinion poll.** See Public opinion poll.

**Opium** is a drug that serves as the source of several medicines, including codeine and morphine. Heroin, an illegal drug, is also made from opium. Opium and most opiates [drugs made from or containing opium] can cause addiction. The United States and many other nations restrict their manufacture, distribution, and use.

Opium is made from the juice of the opium poppy. Most opium used by U.S. drug manufacturers comes from poppies grown on farms in India. Processors near the poppy farms make dried poppy juice, called raw opium, into a brownish powder known as refined opium. They also extract a yellowish powder called morphone base from the opium. Drug manufacturers use refined opium and morphone base to make codeine, morphone, and other medicines.

Heroin and most other illegal opiates are made from morphone base. Most illegal opiates are made in France, Latin America, the Middle East, and Southeast Asia.

**Medical uses.** Opium ranked as the most effective pain-relieving drug until the development of morphone in the early 1800s. Opium was also used to stop coughing and diarrhea, to ease worry, and to cause drowsiness. Opiates serve many of the same purposes today. Physicians prescribe morphone to relieve severe pain. Codeine, probably the most widely used opiate, stops coughing. The opiate paregicor controls diarrhea.

**Opium addiction.** The misuse of opium or of drugs made from it can lead to addiction. Opium, when first used, can give users a feeling of extreme calm and well-being. Their troubles may seem unimportant, and they temporarily live in an unreal world of isolated contentment. People smoke, sniff, or eat opium for these effects. But an addict may have vivid dreams and daydreams that may be extremely unpleasant. Opium addicts tend to neglect their health and their families.

Addicts who want to stop taking opiates can obtain medical treatment and counseling. Some experimental programs use a drug called methadone to help patients overcome addiction to opiates (see Methadone).

**History.** The use of opium began at least 6,000 years ago in the Middle East. Greek and Roman physicians prescribed the drug before the time of Christ. Arabian traders took opium to China and India, probably starting in the A.D. 600s. At first, the Chinese used the drug chiefly as a medicine. European traders introduced opium smoking into China in the early 1600s. The Chinese government outlawed opium in 1729, but traders continued to exchange it for silk, porcelain, and other Chinese products. In the late 1700s, opium addiction became widespread among the Chinese. The opium trade helped cause the so-called Opium War (1839-1842), in which England defeated China (see China [Clash with the Western powers]). During the 1800s, people in the United States and Europe could buy laudanum, morphine, and other opiates legally and without a prescription. By 1900, at least 200,000 Americans had become addicted to opiates. The Harrison Act, a group of laws passed in 1914, greatly reduced the problem in the United States. Addiction to opiates, particularly heroin, began to increase in the late 1940s and has continued to rise ever since. Today, a number of nations and international organizations cooperate in fighting the illegal manufacture and sale of opium and opiates.

**Opossum,** *uh PAHS uh*m, is any member of a family of furry mammals that live in the Western Hemisphere. The female opossum carries its young in a pouch on its abdomen. Opossums, kangaroos, and other mammals that give birth to extremely undeveloped young are called marsupials. Opossums are the only marsupials that are native to North America. They live from Ontario in Canada southward into South America.

There are many species of opossums, most of which live in Central and South America. Small, tree-dwelling *murine opossums* resemble mice. *Wooly opossums* have thick, soft fur. Another kind of opossum, the *yapok*, is the only marsupial that is adapted for living in water. Its webbed feet help make it a good swimmer.

The common opossum is the only kind of opossum found in the United States. This species grows about as big as a house cat. It has rough grayish-white hair, a long snout, dark eyes, and big hairless ears. This opossum has a long tail that does not have much hair on it. The animal can hang upside down by wrapping its tail around a tree branch. This opossum has 50 teeth, more than any other North American mammal. Its teeth and claws are sharp. Opossum tracks are easy to recognize because the animal has long, widely separated toes.

Opossums are born in groups of from 5 to 20. At birth, an opossum is only about as big as a kidney bean. The female opossum carries its tiny babies in a pouch on the outer skin of its abdomen for about two months.
A mother opossum carries its young on its back. Baby opossums stay in their mother's pouch for about two months after birth. They remain near her for several more weeks.

after birth. After leaving the pouch, the young stay near the mother for several more weeks. When they can take care of themselves, the young go off on their own.

Opossums hunt at night. They eat almost any kind of animal or vegetable food. When in danger, opossums sometimes "faint" and appear to be dead.

Frank B. Colley

Scientific classification. Opossums make up the opossum family, Didelphidae. The scientific name for the common opossum is Didelphis marsupialis.

Oppenheimer, AHP uhn ir muhr, J. Robert (1904-1967), an American physicist, became known as the father of the atomic bomb. From 1943 to 1945, he directed the laboratory at Los Alamos, N. Mex, where the design and building of the first atomic bomb took place.

From 1947 to 1952, Oppenheimer headed the advisory committee of the newly formed United States Atomic Energy Commission (AEC). He also advised the U.S. Department of Defense and helped write the first United States proposal for international control of nuclear energy.

In 1953, Oppenheimer's loyalty to the United States was questioned. The charges of disloyalty gave rise to probably the most famous security hearing of the 1950's. Oppenheimer's opposition to the development of the hydrogen bomb, together with his past associations with Communists, led to an investigation in 1954 by an AEC security panel. The panel cleared Oppenheimer of all charges of disloyalty, but it denied him further access to secret information. In 1963, the AEC gave Oppenheimer his highest honor, the Enrico Fermi Award, for his contributions to theoretical physics. Many people viewed this as an effort by the government to correct a tragic mistake.

Oppenheimer was born in New York City. He graduated from Harvard University in 1925 after three years of study. In 1927, Oppenheimer received a doctor's degree from the University of Göttingen in Germany. From 1929 to 1947, Oppenheimer was on the faculty of the University of California at Berkeley, where he established a leading center for research in theoretical physics. During that time, he also taught part of each year at the California Institute of Technology. Oppenheimer served as director of the Institute for Advanced Study in Princeton, N.J., from 1947 to 1966.

Roger H. Stuewer

Opposition is a term that describes the relative position of two heavenly bodies when the earth comes closest to being directly between them. At full moon, for example, the moon is in opposition to the sun. The term is most commonly used to describe positions with respect to the sun. When a superior planet—that is, one whose distance from the sun is greater than the earth's—is on the opposite side of the earth from the sun, it is said to be in opposition. For example, the planet Mars is in opposition when the earth is directly between Mars and the sun.

Lee J. Rickard

Optic nerve. See Eye (The retina; diagram).

Optical disc. See Compact disc.

Optical fiber. See Fiber optics.

Optical illusion. As we look down a long, straight road, we see that it seems to grow narrower in the distance. Trees and telegraph poles along the road appear to grow smaller as they stretch away toward the horizon. We know that a white house looks larger than the same house painted a dark color, and that a man wearing a suit with up-and-down stripes looks thinner than he would if the stripes went crosswise. We call appearances of this kind optical illusions because we know that in such cases things are not the way they appear to be.

Optical illusions of the kind described above are called "normal" illusions, because every person with normal eyesight experiences them. But an optical illusion does not occur every time we are deceived by what we see. Often we make mistakes in interpreting the impressions our eye receives. For example, many persons will read the sentence "he walked though the busy street," and never notice that the third word has no "r" in it. They expect to see "through" and therefore they do
Some common optical illusions

Lines A-B and B-C in the above figure are equal in length. However, line B-C appears to be longer because of the angles of the other lines in the figure.

These blocks are all the same size, but the ones drawn to appear farther from the viewer seem larger. This illusion occurs because the blocks are not drawn in perspective.

This staircase has stairs that run up from right to left. But the figure can also be seen as an upside-down staircase, with the stairs running "up" from left to right.

see "through." Such mistaken impressions are not optical illusions. David E. Eifrig

See also Color (Surprising color-vision effects); Perception (Factors affecting perception; illustration: Perceptual effects); Mirage.

Optics is the branch of physics and engineering that is concerned with the properties of light. It describes how light is produced, how it is transmitted, and how it can be detected, measured, and used. Optics includes the study of visible light and of infrared and ultraviolet rays, both of which are invisible.

Many instruments, including binoculars, cameras, magnifiers, microscopes, projectors, and telescopes, operate according to the principles of optics. All these instruments have optical devices, such as lenses and mirrors, which transmit and control light. Light is detected and measured with instruments called light meters (see Light meter).

Scientists have used the principles of optics to increase the number of ways to use light. For example, they can transmit light along a twisted or curved path by sending the light through a filament called an optical fiber. Scientists use a device called a laser as an impor-tant and powerful light source (see Laser).

There are three major branches of optics. Physical optics deals with the nature and behavior of light as a wave. Geometrical optics is concerned with optical instruments and what happens when light strikes them. Quantum optics studies the nature of light as individual particles, known as photons.

Basic principles of optics describe what light is and how it behaves. To study visible light, scientists use a prism (wedge of glass) that produces a band of colors called the visible spectrum. Scientists analyze this and other spectra with an instrument called a spectroscope. See Light (Electromagnetic waves); Spectrometer.

A number of different reactions may occur when light strikes the surface of an object. Diffraction, interference, reflection, and refraction are some of the basic principles that describe what may happen. Other principles include the chemical effects of light, dispersion, the photoelectric effect, and polarization. See Light (How light behaves).

History. The development of optics began chiefly during the 1600's. The Italian scientist Galileo built telescopes to observe the planets and the stars. Sir Isaac Newton, an English scientist, experimented with lenses and used a prism to break sunlight into its colors (see Newton, Sir Isaac: Light and color). In Holland, the physicist Christiaan Huygens studied polarization and proposed a wave theory of light.

During the early 1800's, two physicists, Thomas Young of England and Augustin Fresnel of France, did much to confirm Huygens' theory. Young formulated the principle of the interference of light. Fresnel then developed a mathematical formula that supported this principle. Most scientists accepted the work of Young and Fresnel as proof of Huygens' theory.

During the mid-1800's, accurate measurements of the speed of light were made by the French scientists Armand H. L. Fizeau and Jean B. L. Foucault. At about the same time, two German scientists, Robert Bunsen and Gustav Kirchhoff, showed that atoms of chemical elements produced the color bands of the spectrum. In 1864, the British physicist James C. Maxwell introduced the electromagnetic theory of light.

Scientists made several important discoveries in optics during the late 1800's and the 1900's. Such scientists as Albert A. Michelson of the United States, Frits Zernike of the Netherlands, and Dennis Gabor of England received the Nobel Prize for physics for their work in optics. Brian J. Thompson

Optimist International is an association of service clubs in the United States, Canada, and the Caribbean. Membership is by invitation to business and professional people of the local community. Optimist Clubs work to develop optimism as a philosophy of life. They promote good government, respect for law, patriotism, friendship among all people, and service to youth.

Under the motto "Friend of Youth," Optimist Clubs conduct a wide range of service projects for young people. Through their Just Say No program, Optimists provide information and peer support to help children resist the temptation to become involved with drugs. The clubs sponsor an annual essay contest and public speaking contest for young people of high school age. Win-
ners of each contest receive college scholarships. Other programs for young people include Bike Safety Week, Youth Appreciation Week, and an international golf tournament called the Optimist Junior World Championships.

Eleven Optimist Clubs founded Optimist International in Louisville, Kentucky, in 1919. The organization now has about 173,000 members in 4,200 Optimist Clubs. Headquarters of the organization are in St. Louis, Missouri.

**Option.** See Commodity exchange (Options contracts)

**Optometry,** *ahp TAHM uh tree*, is a profession devoted to the care of vision. Optometrists give eye health and vision examinations. They diagnose vision problems that affect a person's ability to see nearby and distant objects clearly and to judge distance. They also test the ability of the eyes to work together and to change focus easily. Optometrists prescribe eyeglasses and contact lenses to correct faulty vision. In the United States, optometrists can perform minor procedures such as removing foreign objects from the eye. They can treat some forms of glaucoma and other eye diseases with drugs. They also may recommend vision therapy to help a person overcome certain vision problems.

To practice optometry in the United States or Canada, a person must pass an examination for a state or provincial license. Optometrists in the United States must have completed two or three years of preoptometry college work and graduated from a four-year school or college of optometry. Most optometry students have undergraduate degrees before entering the professional degree program. All schools and colleges of optometry award the Doctor of Optometry (O.D.) degree. Canada has similar requirements. Additional information may be obtained from the American Optometric Association in St. Louis, Missouri.

**Oracle,** *AWR uh kuhl*, in the ancient Greek world, was a shrine where people came to seek advice from prophets or prophetesses. They were individuals who had special powers to speak on behalf of a god. These sacred persons were believed to have the power to reveal the will of the gods and to foretell the future. The word oracle also refers to the prophet and prophetesses, and to their prophecy.

The most important oracle was in Delphi in central Greece, and was dedicated to the god Apollo. The prophetess of Delphi, often called the Pythia, sat on a large three-legged stand or tripod. In a state of ecstasy inspired by Apollo, she frequently uttered her oracles in a strange and puzzling form. The meaning of the Pythia's oracles was often so unclear that priests at the shrine interpreted them for the public.

Most oracles were dedicated to Apollo. Some were dedicated to Zeus or other gods. One famous oracle of Zeus was in a grove of oak trees in Dodona in northwestern Greece. The people believed that Zeus spoke through the rustling of the oak leaves. The priests at Dodona interpreted these rustlings. Other important oracles were in Italy, Libya, and Syria. John Hamilton

**Oran,** *oh RAN* or *aw RAHN* (pop. 1,110,000), is a Mediterranean seaport in Algeria. It lies about 225 miles (362 kilometers) west of Algiers. For location, see Algeria (map).

Oran trades with cities of inland Africa and ports of southern Europe. It was founded by Muslim sailors from Spain in the A.D. 900's. The city was captured by the Spaniards in 1509, by the Turks in 1708, and again by the Spaniards in 1732. Spain abandoned Oran after much of it was destroyed in 1791 by an earthquake. The Santa Cruz fort, built by the Spaniards between 1698 and 1708, still overlooks the city from a nearby hill. In 1831, the French occupied Oran. During World War II (1939-1945), Allied forces landed near Oran as part of the campaign to drive the Axis powers from North Africa.

Kenneth J. Perkins

**Orange.** See Color.

**Orange** is a popular citrus fruit enjoyed by people throughout the world. Oranges are valued for their delicious juice and high vitamin C content. They are an excellent source of potassium and also contain thiamine and folic acid.

About 65 million tons (60 million metric tons) of oranges are harvested throughout the world each year. Brazil is the leading orange-producing nation in the world.

In the United States, over 11 million tons (10 million metric tons) of oranges are harvested yearly—more than any other fruit. Florida produces about 70 percent of the U.S. crop, and California grows most of the rest. Arizona and Texas also produce oranges.

About three-fourths of the oranges grown in the United States are processed into frozen concentrated or fresh juice. Small amounts of oranges are used for making baked goods, candy, marmalade, salads, and soft drinks. Most of the remaining orange crop is sold as fresh fruit. The orange peel, pulp, and *rag* (core) are used primarily as cattle feed supplements.

There are several types of oranges, the most popular of which is the sweet orange. Oranges vary in shape from round to oval, and the peel ranges from pink to orange to dark red in color. They grow best in regions with warm summers and cool winters in which the temperatures do not go below freezing. Freezing temperatures can seriously damage the tree and the fruit.

**The fruit and the tree**

The orange is a type of berry called a *hesperidium*. The peel consists of a colored outer layer called the *flavedo* and a white, spongy inner layer known as the *albedo*. The flavedo contains tiny glands that contain a mixture of aromatic oils. The edible interior of the orange consists of 10 to 15 segments, which surround a spongy core. The segments contain many *juice sacs*, which hold the juice and make up the pulp of the orange. The segments of some varieties of oranges also contain seeds. Other varieties of oranges are seedless or nearly seedless.

The orange tree has dark green leaves and beautiful, white, fragrant flowers. Fruits develop from the ovaries of the flowers. Some varieties of oranges may be harvested within 7 months after the flowers bloom, but others may remain on the tree up to 16 months. Growers plant different varieties of oranges in the same area so
that mature fruit is available during most or all of the year.

Orange trees develop new branches during periods of rapid growth called growth flushes. During these growth flushes, new stems, leaves, and, often, blossoms appear on the trees and some of the flowers develop into fruit. The number and timing of growth flushes that occur each year vary according to the climate. In climates like those of Florida and California, growth flushes do not occur during the winter. Instead, a period of vigorous growth takes place in the spring, during which many flowers appear on the trees and a large number of fruits develop.

**Varieties**

The word orange commonly refers to three types of citrus fruit: (1) sweet oranges, (2) sour or bitter oranges, and (3) mandarins.

**Sweet oranges.** Growers around the world raise more sweet oranges than any other type of citrus fruit. These oranges have a sweet flavor and are round to oval in shape. There are four groups of sweet oranges: (1) common or round oranges, (2) navel oranges, (3) blood oranges, and (4) acidless oranges.

**Common oranges** are the most important type of sweet orange. Most oranges sold as fresh fruit are common oranges. In addition, almost all orange juice is made from common oranges. Juice from the Valencia orange, a type of common orange, makes the highest quality juice products. The Valencia is the most popular variety of orange in the world.

**Navel oranges** have a small secondary fruit growing at one end of the main fruit. They are seedless and have a pleasant flavor, but they produce less juice than do common oranges. California produces most of the U.S. navel-orange crop.

**Blood oranges** have an unusual color, but in other ways are similar to common oranges. The flesh and peel of blood oranges range in color from pink to red. The oranges only become red in climates with cool night temperatures. Blood oranges are widely grown in Mediterranean countries. Few are planted in other areas of the world.

**Acidless oranges** have a low level of acid in their juice and consequently have a bland flavor. Acidless oranges have very little commercial value except in Brazil.

**Sour or bitter oranges** generally are not eaten fresh because the flesh has a bitter taste. Sour oranges are grown mainly in Europe and are widely used in making marmalade. Oils from the peel of some sour oranges and ingredients from the leaves and flowers are used in manufacturing perfume.

**Mandarins** are a group of fruits that includes true mandarins, tangerines, and various hybrids, such as tangels and tangors. Mandarins are not really oranges, but they are often referred to as such because of their orange color. Mandarins taste sweet and are generally eaten fresh. Their peel separates easily from their edible interior. See Tangelo; Tangerine; Tangor.

**Raising oranges**

**Planting and caring for orange trees.** Most orange trees are grown from buds in special nurseries. A small piece of stem containing a bud is cut from a tree that produces the variety of orange desired. The stem is then grafted to a seedling orange tree called a rootstock (see Grafting [Other kinds of grafting]). Rootstock varieties are selected for their ability to produce high-yielding trees, adapt to the local soil and climate, and resist pests and disease. Orange trees are transplanted in groves 6 to 12 months after grafting. They start to bear fruit 2 to 4 years later and may produce oranges for 50 years.

**Pests and diseases.** Orange trees may be attacked by many pests and diseases. Scale insects suck the sap from the fruit, leaves, and twigs. Certain wasps kill these insects, so growers foster the growth of these wasps in the orange groves. Two other sucking pests, rust mites and aphids, also damage the leaves. These pests are killed by spraying the trees with pesticides. Nematodes and weevils may attack orange roots.

Viruses diseases weaken or kill orange trees. The virus disease tristeza is especially deadly. Growers fight these diseases by planting virus-free trees that can naturally resist or tolerate the viruses. Such fungal diseases as melamone and greasy spot also cause extensive damage. Melanose produces tiny, raised dots on the stems, leaves, and fruit. Greasy spot causes oily-looking blotches on the leaves. Growers control fungal diseases by spraying the trees with fungicides.

**Harvesting and processing.** As oranges mature, the amount of sugar and juice they contain increases and their acid content decreases. In the United States, state and federal laws determine the levels of sugar, juice, and acid that oranges must contain to be considered mature. Oranges and other citrus fruit differ from most other fruit in that they do not mature further after they have been harvested. For this reason, growers pick the
Harvesting oranges that are to be sold as fresh fruit involves clipping the ripe fruit by hand. If the oranges are pulled from the trees roughly, they may be damaged.

Oranges only when the fruit contains the required levels of juice, sugar, and acid.

If oranges are pulled from the trees roughly, they may be bruised or damaged, especially at the point where the stem joins the fruit. These damaged fruit may be easily attacked by fungus diseases that cause decay. For this reason, oranges that are to be sold as fresh fruit are either clipped or carefully harvested from the trees by hand. They are then transported to packing houses in large bins that hold about 900 pounds of oranges (400 kilograms). These oranges are then washed and dried. Next, they are waxed with a special coating that prevents dehydration and improves their appearance. The oranges are then graded, sized, packed into boxes, and shipped to markets. Some mature oranges have a partly green peel and may be treated with ethylene gas to reduce the green color of the peel.

Oranges that are to be sold for processing are usually transported in bulk by truck. If they are processed within a few days after harvesting, no serious fruit losses are suffered from bruising or decay. The juice is extracted from the fruit by machine and is then heat-treated to kill harmful bacteria, yeast, and mold, and to inactivate enzymes.

History

Oranges are among the oldest cultivated fruits. People have grown oranges for more than 4,000 years. Oranges probably originated in the part of Asia that now includes India, Myanmar, and southwestern China. By the A.D. 800's, Arab traders had introduced oranges into eastern

Africa and the Middle East. In the 1400's, Portuguese travelers carried oranges from India to Europe. The Italian explorer Christopher Columbus brought orange seeds to America in 1493. During the 1500's, Euro-

pean settlers planted orange trees in Florida and Brazil. The first orange groves in California were established by Spanish missionaries in the late 1700's. The major varieties of oranges grown today were selected during the 1800's. Several new varieties were developed in the late 1900's by crossbreeding oranges with grapefruit or tangerines.

The U.S. orange industry has grown rapidly since the early 1900's. At that time, oranges were rare and expensive, and many people ate them only as a treat on holidays. Today, because of improved growing methods and other factors, most people in the United States can afford oranges and orange juice throughout the year.

Wilfred E. Wardowski

Scientific classification. Oranges are members of the rue family, Rutaceae. Sweet oranges belong to the species *Citrus sinensis*. Sour oranges are classified as *Citrus aurantium*. Mandarins are the fruits of several species and their hybrids. True mandarins belong to the species *Citrus reticulata*.

Orange Free State is a historic region in South Africa. Before Europeans conquered the area in the 1830's, most of its inhabitants were people of the Sotho group of black Africans. About 1836, Boers from Cape Colony settled the region. The Boers named the area the Orange Free State in 1854.

In 1899, disagreements between the Boers and the British led to the Boer War (1899-1902). The Boers were defeated. In 1910, the Orange Free State became one of the four provinces of the Union of South Africa (now the Republic of South Africa). In 1994, South Africa increased the number of its provinces to nine. The Orange Free State remained a province, but the province's name was changed to the Free State in 1995.

The Free State covers 49,666 square miles (129,152 square kilometers). Black Africans make up a large majority of the province's population, but white people own nearly all the land. Most of the black Africans work for white farmers or in gold and uranium mines in the northern part of the province. Bloemfontein is the capital of the Free State and the judicial capital of South Africa.

Orange Order is a Protestant organization in Northern Ireland. It seeks to keep Protestants in power in the country and to maintain Northern Ireland's union with Britain. The Orange Order was founded in 1795 by Anglican Protestant farmers in County Armagh, Ireland, in what is now the southern part of Northern Ireland. It grew out of a conflict between Protestant and Roman Catholic farmers who were bidding to become tenants on the same farmlands. The Protestant farmers joined together to drive Catholic families out of the region.

The organization was named for William of Orange. William was the Protestant leader of the Netherlands who, in 1689, overthrew James II, the Catholic king of England, Scotland, and Ireland.

The Orange Order of Northern Ireland is organized into units called lodges. It has about 1,500 lodges and about 100,000 members. The members, called Orange-men, parade through Protestant and Catholic neighborhoods during the "marching season" of July. They sing and carry banners to celebrate past Protestant victories over Catholics.

Paul E. Gallis

Orange River is the longest river in South Africa. It flows westward across the southern part of the African continent. Sandbars and shallow waters make the Orange River useless for navigation. However, the river serves as an important source of hydroelectric power and provides much-needed water for irrigation projects. In some areas, the gravel of the river contains diamond deposits. For the location of the Orange River, see South Africa (terrain map).

The Orange River rises in the mountains of Lesotho and flows into South Africa. It winds west and northwest for about 1,300 miles (2,100 kilometers). It empties into the South Atlantic Ocean at Alexander Bay. The upper river separates Northern Cape and Eastern Cape provinces from the Free State province. The river then flows across the plateaus of central South Africa to the town of Prieska. From Prieska to the Augrabies Falls, the elevation of the river drops steadily. The lower course of the river stretches from the Augrabies Falls to the western coast, flowing through rugged desert country. The lower section separates Northern Cape Province and Namibia.

Much of the Orange River is narrow, with deep gorges. A large sand bar blocks the mouth of the river and prevents passage by seagoing ships. The river has two major branches, the Vaal and Caledon rivers.

The Orange River was named in honor of the Dutch Prince of Orange in the late 1700's. Robert J. Gordon, a Dutch military commander in South Africa, chose the name. Africans who lived in the area had called the river the Gariep. During the 1860's, diamonds were discovered along the river's course. In 1962, the South African government announced a development plan for the Orange River. Since then, the government has built dams on the river to provide hydroelectric power. It has also built canals and tunnels to irrigate nearby land and to provide flood control.

Hartmut S. Walter

Orangutan, oh RANG u tan, is a large, red-haired ape that lives in the tropical rain forests on the islands of Borneo and Sumatra in Southeast Asia. Orangutans are the largest tree-dwelling mammals. A male orangutan stands about 4 1/2 feet (140 centimeters) tall and weighs about 180 pounds (80 kilograms). Mature males have broad cheek pads that jut out from the sides of their face and a large throat pouch. Females are about half as large as males. They have no cheek pads and only small throat pouches.

An orangutan's arms are extremely long compared to its legs and upper body, reaching to its ankles when the animal stands erect. Orangutans also have long, curved fingers and toes that help them grasp branches, making them well-suited for life in trees. They eat and sleep high in the treetops and rarely come to the ground.

Orangutans feed mainly on figs and other fruit. They also eat leaves, bark, and occasionally insects. Orangutans build nests of woven branches for resting and sleeping. They make and use simple "tools" such as sticks that they have stripped of leaves.

Orangutans are less social than other apes. Adults live far apart in the forest and usually avoid one another. Males and females spend several days together when they mate but then part. Females and their young occupy an area called a home range. Strong, mature males have a large home range that includes the ranges of
several females. Younger males may roam the forest. If two males meet in the presence of a female, they may fight. Orangutans once lived throughout southern China and Southeast Asia. Today, they are an endangered species. The chief causes of their endangerment include destruction of their habitat, hunting, and the collection of animals for zoos. Laws protect the remaining orangutans and preserve their habitat.

Scientific classification. Orangutans belong to the great ape family, Pongidae. The scientific name for the Bornean orangutan is Pongo pygmaeus pygmaeus. The Sumatran orangutan is Pongo pygmaeus abelli.  Randall L. Susman

See also Ape.

Oratorio is a dramatic vocal composition usually based on a religious story. Oratorios resemble operas. Both tell a story and are performed by solo singers, a chorus, and an orchestra. The main difference is that oratorios have no acting, costumes, or scenery. Most oratorios are presented in concert halls or in churches.

In oratorios, soloists often portray specific characters, and the chorus usually is an important element. Although there is no acting or scenery, such theatrical effects as fires and storms can be suggested by the music. Many oratorios have a narrator who introduces the story and supplies details.

Oratorios developed from musical settings of religious texts during the Middle Ages. However, the form as it is known today emerged in Rome in the mid-1500s. The most important period of oratorio composition was the 1600s and 1700s. The German-born composer George Frideric Handel was the greatest composer of oratorios. His Messiah (1742) is the most famous oratorio ever written. Amateur and professional groups, especially in the United States and the United Kingdom, still perform oratorios regularly. Katherine K. Preston

See also Cantata; Handel, George Frideric.

Oratory is the art of eloquent speaking. An orator is a speaker who tries to persuade listeners by logical arguments and emotional appeals to their feelings. An oration is a speech that uses principles of rhetoric (the art of using words for persuasion). An oration, unlike a public speech, has a formal style and includes similes, metaphors, and other figures of speech.

Beginnings. A mass of lawsuits arose when a democracy was established in Syracuse in Sicily in 466 B.C. They were brought by former exiles whose property had been seized by the tyrants. Many claims were several years old, and documentary evidence was often lacking. The claimants needed help in presenting their cases. Corax, a Sicilian Greek, was the first to supply this help, and is considered the founder of oratory. He established a system of rules for public speaking in the 460s B.C., with the aid of his pupil Tisias.

Corax said that a speech usually should have five parts. He described these parts as (1) proem (introduction); (2) narrative; (3) arguments; (4) subsidiary remarks; and (5) summary.

Other early teachers of rhetoric include Protagoras, who developed the principles of debate; Gorgias, who emphasized style; Hippias, who was chiefly interested in the use of memory; and Lysias, who "showed how perfect elegance could be joined to plainness."

The study of speechmaking spread to Athens. During the 400s B.C., almost all male Athenian citizens attended the general assembly, where public policies were debated. They took part in the formulation of policies and the administration of justice. In the courts, they acted as jurors. The decision in each case rested with the jury, because there were no judges. Those who brought the charges and those who defended themselves pleaded their own cases. This practice led to a study of speechmaking.

A male and female orangutan have different physical features. The male, right, has broad cheek pads and a large throat pouch. He is twice as big as the female, left, who has no cheek pads.

Charles R. Belisky, Photo Researchers
Classical orators. The first great Greek orator was Pericles. His speeches were reported by Thucydides in his famous History of the Peloponnesian War. Pericles's Funeral Oration is his best-known speech. The greatest Greek orator was Demosthenes. He is best known for his Philippics, speeches in which he attacked Philip II of Macedonia as a threat to Greek independence.

The outstanding Greek writer on rhetoric was Aristotle. He defined rhetoric as "the faculty of discovering in every case the available means of persuasion." Aristotle emphasized three methods of proof: (1) ethical (the influence of the speaker's personality); (2) pathetic (the influence of the speaker's use of emotional appeal); and (3) logical (the influence of the use of formal principles of reasoning in proof).

Cicero holds first place among the important early Roman orators. Authorities believe that the Rhetorica ad Herennium was written by Cicero about 66 B.C. It states that an orator must divide the preparation of a speech into five steps. These steps are: (1) invention (analysis of speech situation and audience, investigation and study of subject matter, and selection of speech materials); (2) disposition (the arrangement of the speech materials under what we now call introduction, discussion, and conclusion); (3) style (the use and grouping of words to express ideas clearly, accurately, vividly, and appropriately); (4) memory (methods of memorizing material); and (5) delivery (the oral presentation).

Book I of Cicero's De Oratore, written about 55 B.C., develops the theme that a great orator must be a person of great learning and that the "proper concern of an orator ... is language of power and elegance accommodated to the feelings and understandings of mankind."

Book II emphasizes the importance of invention and disposition, with particular attention to court oratory. Book III deals with style and delivery.

Institutio Oratoria (The Training of an Orator), written by Quintilian about A.D. 90, was a complete manual for the training of public speakers. Even today, it is one of the most comprehensive works on training speakers.

Later orators. With the coming of Christianity, the preacher replaced the political speaker. Famous early preachers include Paul, John Chrysostom, and Augustine. Outstanding speakers for religious reform were Savonarola in the late 1400's and Martin Luther and John Calvin during the Reformation in the 1500's.

Political oratory again became important in the 1700's. During the French Revolution, Comte de Mirabeau spoke for the common people fighting royal authority.

Britain has produced many distinguished speakers. They include Edmund Burke, Benjamin Disraeli, William Gladstone, and Winston Churchill.

American orators include Patrick Henry, John C. Calhoun, Daniel Webster, Stephen A. Douglas, and William Jennings Bryan. James M. Copeland

Orbit is the path of a natural or artificial object that moves under the influence of a central force. In astronomy, the term orbit refers specifically to the path of any object whose motion is controlled by the gravitational pull of another object. Astronomers call the more massive of the two objects the primary; and the less massive one the secondary. The moon, for example, is a secondary that revolves around its primary, the earth. The earth, in turn, is a secondary that travels around its primary, the sun. Spacecraft can become secondaries of the earth or another planet, or of the moon or the sun.

The orbit of a secondary object within the gravitational pull of a primary object is a closed curve called an ellipse. Perfectly circular orbits rarely occur. In an elliptical orbit, the primary is not in the center of the ellipse. As a result, the secondary travels closer to the primary at certain times than at others. The point in the orbit where a secondary of the earth is nearest the earth is called the perigee. The farthest point is the apogee. For a secondary of the sun, the nearest point in the orbit is the perihelion and the farthest point is the aphelion.

A secondary object may gain enough speed to escape the gravitational pull of its primary. If it attains such escape velocity, its orbit becomes an open curve called a parabola. If a secondary moves faster than escape velocity, its orbit is a flatter open curve called a hyperbola. A spacecraft that leaves its orbit around the earth during a journey toward another planet travels a hyperbolic orbit.

Orchestra seating is designed by the conductor to produce a certain blend of sounds. In this diagram, the strings form a semicircle around the conductor. The woodwind instruments are arranged in the center, with the percussion and brass sections at the rear.

Orchestra is a group of musicians who play together on various instruments. Some African and Asian orchestras consist entirely of percussion instruments, such as drums, gongs, and xylophones. But in most Western nations, a musical group is considered an orchestra only if it includes violins and other stringed instruments. An orchestra differs from a band, which consists chiefly of wind and percussion instruments.

Some orchestras, called string orchestras, have only stringed instruments. On the other hand, dance orchestras resemble bands in most ways but may include a small string section. The word orchestra generally refers to a symphony orchestra, which consists mainly of stringed instruments. Symphony orchestras also have woodwind, brass, and percussion instruments, which enable them to produce a full range of musical sounds.

Symphony orchestras play all types of music, but most of them specialize in classical works. An orchestra may perform alone, or it may accompany one or more instrumental or vocal soloists or a chorus. Orchestras also accompany ballets and operas and provide background music for motion pictures and television productions.

Some symphony orchestras are made up entirely of professional musicians. Most of the world’s major cities have a professional symphony, and some cities have several. They include such large, well-known orchestras as the Berlin Philharmonic, the Boston Symphony, the Chicago Symphony, the London Symphony, the New York Philharmonic, the Philadelphia Orchestra, and the Vienna Philharmonic. Many smaller communities, especially in Western countries, also have a symphony orchestra. These orchestras consist chiefly of amateur musicians. Many schools in Western countries have student orchestras.

The structure of a symphony orchestra

Orchestral music is written in the form of a score, which shows the notes to be played by each instrument. Most scores call for about the same kinds of instruments, and so most orchestras have a similar structure. A typical orchestra has about 20 kinds of instruments, but the number of each varies among different groups. A large orchestra may have more than 100 musicians, and small orchestras have from about 15 to 40 players. The small groups are often called chamber orchestras. During a performance, only the conductor follows the complete score. The printed music used by the musicians shows only their individual parts.

The musicians are divided into four main groups called sections: (1) the string section, (2) the woodwind section, (3) the brass section, and (4) the percussion section. The various instruments in the string, woodwind, and brass sections are pitched in different ranges, like the voices in a chorus. In the following discussion, the instruments in each of these sections are listed in order from those of the highest range to those of the lowest. Some percussion instruments are also tuned to definite pitches, but most of them have an indefinite pitch.

The string section is the heart of a symphony orchestra. It has more than half the musicians and consists of from 20 to 32 violins, 8 to 10 violas, 8 to 10 cellos, and 6 to 10 string basses. The violins are divided into two groups of equal size. The first violins play the highest-pitched part in the string section, and the second violins play the next highest part. The leading first violinist
serves as concertmaster of the orchestra. The concertmaster directs the other musicians in tuning their instruments and may also be the orchestra's assistant conductor.

The woodwind section consists chiefly of flutes, oboes, clarinets, and bassoons. An orchestra has from 2 to 4 of each of these instruments. The musicians in the section also play various other woodwind instruments when a score requires them to do so. For example, a flutist may switch to the piccolo, and an oboe player may double on the English horn.

The brass section consists of 2 to 5 trumpets, 2 to 8 French horns, 2 to 4 trombones, and 1 tuba.

The percussion section includes two or more timpani, or kettle drums; bells and cymbals; wood blocks; and a bass drum, gong, snare drum, triangle, tambourine, and xylophone.

Other instruments are added to an orchestra if a score calls for them. They include such instruments as the harp, harpsichord, organ, piano, synthesizer, and various saxophones.

The conductor directs the musicians by keeping time with the baton or with his or her hands, and by means of gestures and facial expressions. However, conductors do their most important work before a performance—and even before rehearsing a composition.

In most cases, the conductor selects the music to be played at a concert. After selecting a work, the conductor's first job is to interpret the music by deciding exactly how it should be played. Interpretation of a work includes such elements as tempo, tonal quality, and phrasing. After determining these features of the score, the conductor rehearses the music with the players.

During a rehearsal, the conductor asks individual musicians or sections to play various parts of the score again and again until the desired effect has been achieved. He or she strives for the correct balance among the many instruments playing at the same time and adjusts the sound to suit the acoustics of the performance hall. The finest conductors are respected not only for their musical skill but also for their ability to inspire both musicians and audiences.

Most conductors also help audition musicians who apply for positions in an orchestra. A conductor listens to the applicants perform and then recommends who should be invited to join.

Orchestra management. Most major orchestras in the United States are operated by private, nonprofit corporations called symphony societies. The chief concern of a symphony society is to raise funds to help support the orchestra. The board of directors of the society also acts on the conductor's recommendations regarding
musicians to be offered positions in the orchestra. Most professional orchestras have a business manager to handle most of the administrative work. The business manager works out the orchestra's budget; prepares employment contracts; plans rehearsal, concert, and recording schedules; and organizes ticket sales and publicity.

History

The term orchestra was first used by the ancient Greeks for the front area of a stage. During the Middle Ages, orchestra came to mean the musicians on that part of the stage. In modern times, orchestra has come to mean both the musicians on stage and the seats directly in front of the stage.

Beginnings. The first orchestras were organized at the royal court of France and in Italian churches and palaces during the late 1500's and the 1600's. At first, orchestras served chiefly to accompany social dances, ballets, religious vocal music, and operas. Most of these orchestras consisted mainly of string instruments. In Germany, wind instruments were also popular. Except in France, these orchestras had no standard structure. String, wind, and percussion instruments were often mixed. The orchestra of King Louis XIII of France was the first standardized orchestra. It had 24 instruments of the violin family, divided into five sections, and 12 wind instruments. Beginning in the 1600's, most orchestras also played a bass line called a basso continuo, usually with a lute, harp, organ, or harpsichord.

The 1700's and 1800's. By the early 1700's, some European composers also began to write music for orchestra in its own right. These composers included Johann Sebastian Bach, Arcangelo Corelli, George Frideric Handel, and Antonio Vivaldi. Their compositions were called concerti, concerti grossi, overtures, and suites.

Orchestral works called symphonies first appeared as overtures or small instrumental interludes in operas about 1600. By the 1720's and 1730's Giovanni Battista Sammartini began to write independent string symphonies in Italy. In the late 1700's, Joseph Haydn and Wolfgang Mozart, perfected the classical symphony. The clarinet became standard in the symphony orchestra in the 1790's. In the early 1800's, Ludwig van Beethoven composed the first symphonies that included trombones and voices.

During the 1800's, cities began to take over patronage of orchestras. Many orchestras were regularly engaged in accompanying operas in municipal opera houses and also played concerts on the side. A few, however, were established independently of the opera. The Gewandhaus Orchestra of Leipzig, Germany, is the oldest orchestra still playing. It was founded in 1781. The Paris Conservatory Orchestra was established in 1800, and what is now the Royal Philharmonic Society was founded in 1813.

Until the early 1800's, orchestras were small enough to perform without a conductor. The concertmaster or a keyboard player in the basso continuo served as the leader. By 1830, orchestras had grown so large that nearly all were led by a conductor. Composers Hector Berlioz and Felix Mendelssohn were among the earliest conductors. Berlioz was one of the first to conduct with a baton.

Popular types of orchestral music in the 1800's included symphonies, overtures, symphonic poems, and concertos. Orchestras also continued to accompany opera, ballet, and religious music. In the late 1800's and early 1900's, such composers as Richard Wagner, Anton Bruckner, Gustav Mahler, and Richard Strauss wrote works for orchestras of 100 or more musicians.

Modern orchestras. Since the early 1900's, there has been renewed interest in works for smaller orchestras. Some composers have added electronic instruments or reorganized the orchestra into groups to create new kinds of musical sounds. Today, most large orchestras have several conductors on their staffs.

The symphony orchestra originated in Europe, but its form has been copied throughout the world. There are now many symphony orchestras in non-European countries including Argentina, Australia, Brazil, China, Israel, Japan, and Mexico. The first orchestras in the United
States were formed in the late 1700's. The oldest American orchestra still performing is the student orchestra at Harvard University, which was formed in 1808. Important orchestras in the United States include the New York Philharmonic (1842), the Boston Symphony (1881), the Chicago Symphony (1891), and the Philadelphia Orchestra (1900).

The cost of maintaining an orchestra has increased dramatically since the mid-1900's. The income from ticket sales pays only a fraction of an orchestra's expenses. Many European orchestras rely heavily on funds that they receive from government sources. In the United States, many orchestras receive additional funds from both private and public sources and from recording royalties. Organizations such as the National Endowment for the Arts, an independent federal agency, distribute funds to symphony societies. Some orchestras have sought other sources of funding in new types of programming. For example, these orchestras have provided background music for movies, radio, and videos.

Orchestra bells imitate the effect of authentic cast bronze chimes and metal bars. The two types of orchestra bells are tubular chimes and metal bars. The chimes are usually from 1 to 2 inches (2.5 to 5.1 centimeters) in diameter and vary in length with the pitch. They are hung from a metal frame, and are struck with heavy leather-headed mallets. Their sound is deep and resonant. The metal bars are of varying sizes, usually not more than 0.5 inch (13 millimeters) in thickness, and are arranged in rows much like the piano keyboard. They are struck with a hard mallet, and produce a ringing sound, more brilliant and higher pitched than that of the tubular, hanging chimes.

John H. Beck

See also Glockenspiel; Xylophone.

Orchid, *AWR kihd*, is any of an extremely large family of plants, many of which bear beautiful flowers. There are as many as 20,000 species of these plants. They are widely cultivated as house, garden, and greenhouse flowers, and they also grow wild. Orchids are perennials, which means the plants live for at least three years.

Orchids range in size from small plants only 0.5 inch (0.6 centimeter) high to vines as much as 100 feet (30 meters) long. The flowers come in all colors except black, and they may be speckled or streaked.

Wild orchids grow in all parts of the world except Antarctica. They are most abundant in regions with plentiful rainfall. Most species grow on the trunks and branches of trees, or on rocks, in warm or tropical areas. Wild orchids that live in cooler regions grow on the ground. Some species even inhabit desert regions. The Australian *underground orchids* live below the surface of the soil in order to conserve water.

Parts of orchids. Like lilies, orchids have three inner petals and three outer, petal-like *sepals*. However, unlike lilies, orchids have a central petal that is usually larger and more showy than the other petals. This petal is called the *lip* or *labellum*. It may look like a cup, a scoop, a trumpet, or a bag. Among most orchids, each flower has one *stamen* (male part) and one *pistil* (female part) at its center. The stamen bears pollen grains, which usually occur in large clusters called *pollinia*. The pollen produces sperm cells, while the pistil contains egg cells. Among these orchids, the stamen and the pistil are joined, forming a *column*.

How orchids reproduce. Most orchids reproduce by *cross-pollination*. In this process, an insect, a bat, or a bird carries pollen from the stamen of one flower to the pistil of a flower of another plant. An orchid's fragrance and the size and shape of its blossoms may attract certain kinds of insects or birds. For example, many orchids look or smell like bees, attracting bees to the flowers. After pollination occurs, sperm cells unite with egg cells in the pistil and seeds develop. Orchid seeds are so tiny that they need the help of certain types of fungi.
As many as 20,000 species of orchids grow in most parts of the world. These beautiful flowers have a wide variety of shapes and colors. Some of the orchids shown below grow in various countries and have no common name in English. The scientific name is given for such flowers.
to begin their growth. These fungi supply the seeds with various substances needed for growth.

Kinds of orchids. Most botanists divide orchids into three groups, according to the number of stamens and the form of the column in the flower. The largest group of orchids—more than 96 percent of all species—have flowers with a completely joined column that typically contains one stamen. This group includes the vinelike *vanilla orchids*, which grow in Mexico and throughout the tropics. Vanilla, a flavoring in many foods and beverages, occurs naturally in these orchids (see Vanilla).

Species with two stamens almost completely joined in the column make up a group called *lady's-slippers* (see *Lady's-slipper*). A third group consists of orchids with two or three stamens that are at most only partly joined in the column. Margaret R. Bolick

Scientific classification. Orchids make up the orchid family, Orchidaceae. There are three subfamilies: Orchidoideae, Cypripedioideae, and Apostasioideae.

See also Flower (pictures: The fly orchid; Clamshell orchid); Root (picture: Specialized roots).

Orczy. See Pluto.

**Orczy, AWRT see, Baroness** (1865-1947), was a Hungarian-born English author known chiefly for her adventure-filled novels and detective stories. She also wrote several plays.

Orczy's most famous novel, *The Scarlet Pimpernel* (1905), is set during the French Revolution (1789-1799). The hero, an English aristocrat named Sir Percy Blakeney, appears to be an idle, useless person. But, as the mysterious Scarlet Pimpernel, he gallantly rescues aristocrats who have been sentenced to death. This character also appears in 12 other novels.

Orczy created several detectives in various short stories. For example, the nameless Old Man in the Corner solves baffling crimes as he sits in a corner of a London teashop, knitting and unknitting a piece of string. He appears in the story collection *The Old Man in the Corner* (1909). Another detective, Lady Molly Robertson-Kirk, one of the first female detectives, is featured in the collection *Lady Molly of Scotland Yard* (1910).

Baroness Emmuska Orczy was born in Tarnaörs, Hungary, near Jászberény. Her family moved to London when she was 15.

Order of... See plumbing.

**Order** is a unit of scientific classification. Organisms are divided into seven major groups called kingdoms, phyla, or divisions; classes; orders; families; genera; and species. Members of an order are more closely related than are members of a class. However, members of orders are not so closely related as are members of families.

Theodore J. Crovello

See also Classification, Scientific (table).

**Order in Council** is a decree issued by the British Crown when a matter of great importance confronts the nation. Orders in Council get their name from the fact that they are proclaimed with the advice of the Privy Council. In 1807, Britain issued Orders in Council in answer to Napoleon's threat to blockade the island empire. By these orders, British ships blockaded the European coast and kept neutral trading vessels from entering ports of Napoleonic Europe. See also Continental System; Privy Council.

Arthur Cyr

**Order of...** See articles on orders listed under their key word, as in DeMolay, Order of.

**Ordered pair.** See Algebra (Functions).

**Ordinance** is a public law or regulation that is usually made by the governing body of a city, town, or village. In most cases, ordinances are only local in nature. The name ordinance has also been given to regulations that serve as laws in newly settled territories, but are not actually constitutions. The Ordinance of 1787 was such a regulation. It provided for government in the Northwest Territory (see Northwest Ordinance). Ordinance may also refer to a church sacrament, such as Communion.

Susan H. Ambler

**Ordinance of 1785.** See Westward movement in America (Reaching the Mississippi River).

**Ordinance of 1787.** See Northwest Ordinance.

**Ordinance, ARWRD nohns, is a military term used for weapons and ammunition.** Most armies, navies, and air forces have ordinance departments. It is the responsibility of the ordinance departments to design, make, repair, and distribute weapons and ammunition. The term ordinance also includes the tools used in the manufacture and maintenance of these items. Frances M. Lussier

See also Ammunition; Weapon.

**Orovoian Period.** See Earth (table: Outline of Earth's history).

**Ore** is a mineral or rock that contains enough metal to make it worth mining. Ore deposits often occur in cracks of rocks called veins and in layers known as beds. Ore spread thinly in rock is disseminated ore. Worthless minerals mixed in with ore are called gangue.

There are two types of ores—native metals and compound ores. In native metals, the valuable mineral occurs as a pure metal. It is not chemically combined with other substances. Gold, silver, platinum, and copper often occur as native metals. In compound ores, the valuable metal is joined to other substances such as oxygen, sulfur, carbon, or silicon to form various chemical compounds. The ores of iron, aluminum, and tin are usually found joined with oxygen in compounds called oxides. Copper, lead, zinc, silver, nickel, and mercury are found joined with sulfur in compounds called sulfides.

Metal is separated from ore in various ways. In a process called concentration, ore is crushed and ground so that metals separate from gangue. Metals can also be freed from ore and refined by smelting, in which ore is melted. Some metals can be dissolved out of ore by a process called leaching. In the electrolysis process, metals are separated by passing an electric current through a solution that contains metal atoms. See Metallurgy (Extractive metallurgy). William Hustadul

See also Mineral; Rock.

**Oregano, uh REHG uH noh or awvr uh GAH noh, is a seasoning used in many popular foods, including pizza and spaghetti sauce.** Oregano commonly is prepared from the dried leaves of the wild marjoram plant.

Oregano has a strong, sweet flavor. See also Marjoram.
Oregon, a Pacific Coast state of the United States, is known for its vast forests of evergreen trees.Forests cover almost half the state, and many large Oregon cities have factories that make wood products. The state has about a tenth of the nation's timber, and it ranks among the leading states in lumber production.

The rugged beauty of Oregon's mountains, seacoast, and forest lands attracts millions of tourists every year. Hunters shoot deer and elk and other game in Oregon's wooded regions. People enjoy fishing in the sparkling lakes and rivers, and in Pacific waters. Oregon is often called the Pacific Wonderland because of its outstanding natural wonders. These include Crater Lake in the Cascade Mountains, the Columbia River Gorge, Hells Canyon on the Snake River, and Oregon Caves National Monument. Mount Hood, Mount Jefferson, and other snow-covered peaks rise majestically in the Cascade Range. The Wallowas, in northeastern Oregon, also offer spectacular mountain scenery. Steep cliffs rise along much of Oregon's wave-swept coast. But parts of the coast have sandy beaches and protected harbors.

The dry lands east of the Cascade Mountains have large livestock ranches. Potatoes, sugar beets, and other vegetables grow in irrigated areas of eastern Oregon. Wheat, Oregon's most valuable food crop, comes chiefly from the north-central area of the state. Orchard fruits grown in the Hood and Rogue river valleys are world famous.

The mighty Columbia River forms most of the boundary between Oregon and Washington. Huge dams on the Columbia supply electric power for homes and industries. The dams also improve the river for shipping, and provide water for irrigation.

The contributors of this article are Claude W. Curran, Professor of Geography at Southern Oregon University; and Gordon B. Dodds, Professor of History at Portland State University.
Vast fields of golden wheat grow in the plateau area of north-central Oregon. Wheat is one of the state's most valuable crops.

The Columbia River was at one time called the Oregon, or Ouragan, which means hurricane in French. Some authorities think that Oregon's name came from this historic name. Oregon is known as the Beaver State because the region supplied thousands of beaver skins during fur-trading days.

In the early days, Oregon meant the end of the trail for many pioneers. During the 1840's and 1850's, thousands of settlers traveled by covered wagon on the Oregon Trail to the fertile farmlands of the Willamette Valley.

Today, the Willamette Valley is Oregon's greatest center for trade and industry. It is also important for flower bulbs, fruits, milk, seed crops, and vegetables. Most of Oregon's large cities are in the Willamette Valley. They include Portland, the largest city, and Salem, the state capital. Portland extends along both banks of the Willamette River near the place where the Willamette flows into the Columbia. It is an industrial city and a major seaport.

Interesting facts about Oregon

Lava forest

The world's largest forest of lava-cast trees is located on the slopes of Newberry Volcano in Deschutes National Forest, south of Bend. The imprint of pine bark is still visible on the insides of many casts, which were formed about 6,000 years ago when molten lava flowed into a living pine forest. The lava cooled against the tree trunks, which caught fire and burned away, leaving perfect molds. The forest covers about 4 square miles (10 square kilometers).

The first state antilitter law affecting nearly all beverage containers was passed by the Oregon legislature on July 2, 1971, and became effective on Oct. 1, 1972. The law outlaws pull-tab cans and requires that all beverage cans and most types of bottles be returnable for a cash refund.

The world's smallest official park is located on a traffic island on S. W. Front Avenue in Portland. Mill Ends Park is 24 inches (61 centimeters) across and has a total area of 452 square inches (2,916 square centimeters). A Portland journalist, Dick Fagan, created the park on St. Patrick's Day, 1948, as a colony for leprechauns and a site for snail races. It became a city park in 1976.

Downtown Portland rises along the west bank of the Willamette River near Oregon's northern border. Portland is Oregon's largest city and the state's major center of industry and trade.
Oregon in brief

Symbols of Oregon
The state flag, adopted in 1925, bears the state seal. The seal, adopted in 1859, has 33 stars around it to show that Oregon was the 33rd state. The seal includes an ox-drawn wagon to symbolize the settling of the region by pioneers. The reverse side of Oregon's flag, not shown, has an illustration of a beaver, the state animal. Oregon is the only state whose flag has a different design on the reverse side.

General information
Statehood: Feb. 14, 1859, the 33rd state.
State abbreviations: Ore. or Oreg. (traditional); OR (postal).
State motto: She Flies with Her Own Wings.
State song: "Oregon, My Oregon." Words by J. A. Buchanan; music by Henry B. Murtagh.

Land and climate
Area: 97,052 mi² (251,365 km²), including 1,050 mi² (2,718 km²) of inland water but excluding 80 mi² (207 km²) of coastal water.
Elevation: Highest—Mount Hood, 11,239 ft (3,426 m) above sea level. Lowest—sea level.
Coastline: 296 mi (476 km).
Record high temperature: 119 °F (48 °C) at Prineville on July 29, 1898, and at Pendleton on Aug. 10, 1898.
Record low temperature: −54 °F (−48 °C) at Ukiah on Feb. 9, 1933, and at Seneca on Feb. 10, 1933.
Average July temperature: 66 °F (19 °C).
Average January temperature: 32 °F (0 °C).
Average yearly precipitation: 28 in (71 cm).

Important dates
1792  Robert Gray sailed into the Columbia River.
1811  John Jacob Astor's Pacific Fur Company founded Astoria.
1819  A treaty between the United States and Spain fixed the present southern border of Oregon.
1848  Oregon became a territory.
Oregon became the 33rd state on February 14.

Oregon adopted the initiative and referendum, procedures that permit voters to take a direct part in lawmakers.

Bonneville Dam was completed.

Construction was completed on a second powerhouse of Bonneville Dam.
People

Population. The 2000 United States census reported that Oregon had 3,421,399 people. The state's population had increased 20 percent over the 1990 census figure, 2,842,321. According to the 2000 U.S. census, Oregon ranks 28th in population among the 50 states.

About three-fourths of the people of Oregon live in the state's metropolitan areas (see Metropolitan area). For the names and populations of these areas, see the index to the political map of Oregon.

Most of Oregon's large cities lie in the rich Willamette Valley in the northwestern part of the state. Portland, Oregon's largest city, is the commercial, industrial, and cultural center of the state. Portland's lovely rose gardens give it the nickname City of Roses.

Eugene ranks as the second largest city in Oregon. Eugene is a trading and processing center. The largest cities outside the valley are Ashland and Medford in the southwest, and Bend in central Oregon.

Some of Oregon's people trace their ancestry to settlers who came on the Oregon Trail. Oregon's largest population groups include people of German, English, Irish, American Indian, French, Swedish, and Norwegian descent.

Schools. Jason Lee, a Methodist missionary, established a school for Indian children in French Prairie as early as 1834. After the Oregon Territory was organized

Population density

More than half of Oregon's residents live in the Willamette Valley, in the northwestern part of the state. Thinly populated eastern Oregon is largely mountainous.

Runners in Eugene compete in the annual Butte to Butte 10-Kilometer Run through the city. Eugene, Oregon's second largest city, is a favorite training site for world-class athletes because of its extensive running facilities.
in 1848, an act provided that income from two sections (1,280 acres, or 518 hectares) of land in each township should be set aside for education. In 1849, the territorial legislature passed laws providing for a free public school system. The first public school in Oregon opened in 1851.

Today, a State Board of Education heads Oregon's public school system. The governor appoints the seven board members, subject to approval by the state Senate. The superintendent of public instruction is elected to a four-year term. The superintendent oversees the public school system.

Children from age 7 through 17 must attend school. For the number of students and teachers in Oregon, see Education (table).

Libraries. Oregon's first subscription library was organized in Oregon City in 1834. The Library Association of Portland (now the Multnomah County Library) was the first to serve the public on a large scale. It began in 1864 on a membership basis and became a free public library in 1902.

Today, Oregon has about 200 public libraries and branches. The largest library in the state is the Multnomah County Library in Portland. The Oregon State Library in Salem provides information to the state government and serves as the library for the blind.

Museums. The Portland Art Museum displays a large collection of paintings and sculpture. These works feature Indian art from the Northwest Coast and pre-Columbian Mexican art. The University of Oregon Museum of Art in Eugene owns the Murray Warner Collection of Oriental Art, one of the finest in the country. The Oregon Museum of Science and Industry in Portland features interactive exhibits representing every major branch of science. The Oregon Historical Society in Portland features exhibits from pioneer days. The Favell Museum of Western Art and Indian Artifacts is in Klamath Falls.

### Universities and colleges

This table lists the universities and colleges in Oregon that grant bachelor's or advanced degrees and are accredited by the Northwest Association of Schools and Colleges.

**Source:** 2000 census.
Oregon is known for its beautiful mountains and coastal scenery. Majestic snow-covered Mount Hood towers above the Cascade Range about 50 miles (80 kilometers) east of Portland. U.S. Highway 26 skirts Mount Hood and offers close-up views of its glacier-clad slopes. U.S. Highway 101 follows the Oregon coastline for about 300 miles (480 kilometers). Motorists driving along this route see views of white sand dunes, coastal lakes and bays, and cliffs rising above the shore.

Oregon is a recreational paradise. Deer, elk, and pronghorns roam the fields and forests. People catch salmon, steelhead, trout, and other major game fish. Grouse, pheasant, quail, and other game birds are plentiful.

Slopes in the Cascade, Siskiyou, and Blue mountains offer excellent skiing. Timberline, on Mount Hood, offers year-round skiing. The skiing season in most other areas begins in November and lasts through April.

One of Oregon's most famous events is the Oregon Shakespearean Festival in Ashland. Indoor plays are presented from late February through late October. Outdoor plays are presented from June through September. 'Dancing on the Green' before showtime features Shakespearean songs.

Other leading events are the Portland Rose Festival in early June and the Pendleton Round-Up and Happy Canyon Pageant in mid-September. The Rose Festival features parades, stage events, an international rose show, auto races, and a carnival. The festival's main event is a spectacular Grand Floral Parade. The four-day rodeo includes a presentation by local Indian tribes featuring a tepee camp and ceremonial dancing.

### Places to visit

Following are brief descriptions of some of Oregon's many interesting places to visit:

**Bonneville Dam**, the first major dam on the Columbia River, has a series of fish ladders. In season, salmon and other fish jump up the ladders on their way upstream to spawn.

**Columbia River Gorge.** Here the Columbia River cuts through the Cascade Mountains. Colorful basalt cliffs line the gorge for about 60 miles (97 kilometers) between The Dalles and Troutdale. A number of waterfalls tumble into the gorge.

**The Museum at Warm Springs** has interactive historical exhibits and collections of art and artifacts from the Confederated Tribes of the Warm Springs Reservation of Oregon.

**National Historic Oregon Trail Interpretive Center**, in Baker City, has exhibits and demonstrations that re-create some of the experience of traveling along the Oregon Trail.

**Sea Lion Caves**, on the Pacific Coast near Florence, house hundreds of sea lions. The animals can be seen in the caves and on nearby rocks. It is the world's largest sea cave.

**National parks and forests.** Crater Lake National Park, the state's only national park, lies in the Cascade Mountains in south-central Oregon. Crater Lake, 1,932 feet (589 meters) deep, rests at the top of an ancient volcano. See Crater Lake National Park. Ten national forests lie entirely within Oregon. They are Deschutes, Fremont-Malheur, Mount Hood, Ochoco, Siuslaw, Umpqua, Wallowa-Whitman, Willamette, and Winema. Oregon shares Umatilla National Forest with Washington, and Klamath, Rogue River, and Siskiyou national forests with California. Congress set aside 13 areas in Oregon's national forests as national wilderness areas, to be preserved in their natural condition.

**National monuments, memorials, and historic sites.** Oregon Caves National Monument is in southwestern Oregon's Siskiyou Mountains. Its limestone caverns contain beautiful stone formations. John Day Fossil Beds National Monument, in north-central Oregon features fossils of prehistoric animals and plants (see John Day Fossil Beds National Monument). Fort Clatsop National Memorial near Astoria was the site of the winter camp of Meriwether Lewis and William Clark during their expedition to the area in 1805 and 1806. McLoughlin House National Historic Site in Oregon City was built by John McLoughlin, who is often called the *Father of Oregon*. He lived there from 1847 to 1857.

**State parks.** Oregon has over 230 state parks. Many have camping and recreational facilities. Write to Oregon State Parks, 1115 Commercial Street NE, Salem, OR 97301-1002.
Annual events

January-May
- Sled Dog Races in Chemult (January)
- Seafood and Wine Festival in Newport (late February)
- Pear Blossom Festival in Medford (mid-April)
- All Northwest Barber Shop Ballad Contest and Gay Nineties Festival in Forest Grove (early May)
- Rhododendron Festival in Florence (mid-May)
- Fleet of Flowers Memorial Service in Depoe Bay (late May)

June-August
- Cannon Beach Sandcastle Contest in Cannon Beach (June)
- Rose Festival in Portland (June)
- Strawberry Festival in Lebanon (early June)
- Bach Summer Music Festival at Eugene (late June)
- World Class Windsurfing in Hood River (July)
- Butte to Butte 10K run in Eugene (early July)
- Rodeo in St. Paul (early July)
- World Championship Timber Carnival in Albany (early July)
- Buckaroo in Molalla (early July)
- Chief Joseph Days in Joseph (late July)
- Oregon Brewers Festival in Portland (late July)
- Regatta in Astoria (mid-August)
- State Fair in Salem (August-September)

September-December
- Oktoberfest in Mount Angel (mid-September)
- Cycle Oregon Bike Ride, different location each year (September)
- Lord’s Acre Auction and Barbecue in Powell Butte (early November)
- Kraut and Sausage Feed and Bazaar in Verboort (November)
- Whale Watching on the Oregon coast (November-December)
The Columbia Plateau, also called the Columbia Intermontane, covers most of eastern Oregon and extends into Washington and Idaho. Thousands of years ago, lava flowed out of cracks in the earth’s crust to form the plateau. Deep canyons of the Deschutes, John Day, and other rivers cut through the plateau in north-central Oregon. The state’s great wheat ranches lie there. Much of the so-called “plateau” in Oregon is actually rugged and mountainous. The Blue and Wallowa mountains rise in northeastern Oregon. Timberlands cover the Blue Mountain area. The Wallowa Mountains, cut by glaciers, provide spectacular scenery. The Snake River has carved the famous Hells Canyon on the Oregon-Idaho border. This great gorge lies between the Wallowa Mountains and Idaho’s Seven Devils Mountains. Its average depth is about 5,500 feet (1,680 meters).

The Basin and Range Region covers part of southeastern Oregon and extends into California and other nearby states. In Oregon, the region consists of high basins broken by occasional steeply sloped mountains. The Cascade Range to the west cuts off moisture-bearing winds from the Pacific Ocean and makes much of the area a semidesert.

Coastline. Oregon’s coastline extends 296 miles (476 kilometers) along the Pacific Ocean. Much of the shore

Land regions of Oregon
The towering Cascade Mountains include several peaks over 10,000 feet (3,000 meters) high. The Three Sisters rise in the foreground. Mount Jefferson and Mount Hood are in the distance.

is rugged, with steep cliffs rising up from the sea. But many bays and harbors have been formed where rivers from the coast ranges and Klamath Mountains flow into the sea. These bays and harbors include Tillamook, Yaquina, Alsea, Winchester, and Coos.

**Rivers, waterfalls, and lakes.** The mighty Columbia River flows westward to the Pacific Ocean, forming most of the border between Oregon and Washington. The Columbia drains more than half of Oregon. The Columbia and its branch, the Willamette River, form the largest system of navigable waterways in the state. The Snake River forms much of the Oregon-Idaho border. It joins the Columbia in Washington. The Snake and its branches drain the easternmost part of Oregon. The Deschutes River travels northward through central Oregon and empties into the Columbia. The John Day River rises in the Strawberry Mountains in eastern Oregon. It flows west and north to the Columbia and drains much of north-central Oregon.

Hundreds of streams in the Cascade Mountains rush down the slopes and waterfalls. Among the best known waterfalls are Benham, Pringle, Salt Creek, Steamboat, and the many falls along Silver Creek. About a dozen waterfalls, some of them over 200 feet (61 meters) high, tumble into the Columbia River Gorge. These waterfalls include Bridal Veil, Coopery, Elowah, Horsetail, Latourell, and Multnomah.

The Cascade Mountains region has many lakes. Crater Lake in the Cascades, 1,932 feet (589 meters) in depth, is the deepest lake in the United States. It lies in the caldera (crater) of an extinct volcano. Wallowa Lake in the Wallowa Mountains is famous for its sparkling clear water. Most of the lakes in southeastern Oregon are shallow and salty. Some evaporate during dry seasons and leave salt deposits in the lake beds. But a few, such as Harney and Malheur, are large year-round lakes. A number of small lakes near the Oregon coast were formed when deposits of soil and sand blocked the mouths of streams and kept the streams from emptying into the ocean.

**Plant and animal life.** Forests cover nearly half of Oregon. Softwood trees include cedars, firs, hemlocks, pines, and spruces. Hardwoods include alders, ashes, cottonwoods, junipers, madrones, maples, and willows. Many kinds of wild flowers grow in Oregon because the state has a variety of climates and elevations. Oregon is famous for its azaleas, laurels, and other flowering shrubs. The state flower, the Oregon grape, grows in most parts of the state.

Columbian black-tailed deer and Roosevelt elk live in Oregon’s Cascade Mountains and coastal forests. Mule deer, Rocky Mountain elk, and Bighorn sheep are found east of the Cascades. Pronghorn antelope thrive in the southeast. A small number of mountain goats live in the Wallowa Mountains. Smaller animals found in Oregon include bobcats, beavers, coyotes, foxes, minks, muskrats, and river otters. Seals and sea lions live along the coast.

Every year, thousands of salmon leave the ocean and swim up Oregon’s rivers to lay their eggs. They leap up low waterfalls and climb fish ladders to get around dams. Cod, halibut, herring, ling cod, sablefish, sole, and tuna live in Oregon’s coastal waters.

The steelhead trout is perhaps the most prized of Oregon’s many game fishes. Other fishes in the state’s rivers and lakes include perch; striped bass; sturgeon; and cutthroat, brook, and rainbow trout.

**Climate.** Mild, moist winds from the Pacific Ocean give western Oregon an unusually mild climate for a state so far north. Coastal temperatures average 45° F. (7° C) in January and 60° F. (16° C) in July. The winds become cooler when they rise over the coast ranges. Much of their moisture condenses and falls as rain. In some coastal mountain areas, yearly precipitation train,
snow, and other moisture) exceeds 130 inches (330 centimeters).

In the Willamette Valley, east of the Coast Range, precipitation averages about 40 inches (100 centimeters) a year, almost all during the cool season. As the winds rise up the western slopes of the Cascade Mountains, more of their moisture falls. Precipitation in this area averages 50 to 75 inches (130 to 191 centimeters) a year.

The winds are usually dry by the time they have crossed the Cascades. Dry winds do not keep the climate mild, as moist winds do. For this reason, eastern Oregon has relatively cold winters and hot summers. In the southeast, temperatures average 27 °F (−3 °C) in January and 72 °F (22 °C) in July. Much of eastern Oregon receives only 6 to 12 inches (15 to 30 centimeters) of precipitation a year. Oregon's record low of −54 °F (−48 °C) occurred on Feb. 9, 1933, at Ukiah, and on Feb. 10, 1933, at Seneca. The highest temperature, 119 °F (48 °C), occurred at Prineville on July 29, 1898, and at Pendleton on Aug. 10, 1898.

**Average January temperatures**

Moist, mild ocean winds give far western Oregon unusually mild winters for a state so far north.

**Economy**

Service industries, taken together, account for about two-thirds of Oregon's gross state product—the total value of all goods and services produced in a state in a year. However, manufacturing is the single most important industry in the state, accounting for about a fourth of the gross state product. The electronic products industry has grown to become the most important manufacturing activity in Oregon. Factories in the Portland area produce such high-technology products as computers, computer printers, and laboratory equipment. Wood processing, formerly the leading manufacturing activity, still plays a significant role. The economies of many Oregon cities rely almost entirely on this industry.

The Cascade Mountains divide Oregon into two major economic regions. Manufacturing and service industries are concentrated in the Willamette Valley in western Oregon. Western Oregon also produces large amounts of timber, milk, flower bulbs, seed crops, and vegetables. The dry lands east of the Cascades are most important for cattle, wheat, and potato production.

Millions of tourists visit Oregon. Tourism contributes over $5 billion annually to the state's economy.

**Natural resources.** Oregon's many natural resources include vital forest lands, small deposits of many minerals, and a plentiful water supply.

**Forests.** Oregon has almost a tenth of the nation's timber. Forests cover nearly half the state. Oregon has two forest regions: (1) the Douglas-fir region west of the Cascade Mountains, and (2) the ponderosa (western yellow) pine region east of the mountains.

*GSP = gross state product, the total value of goods and services produced in a year. Less than one-half of 1 percent.*

Figures are for 1991.

**Minerals.** Widespread deposits of limestone, sand, and gravel are Oregon's most important mined resources. Sand and gravel are found in almost all parts of the state. The most valuable limestone deposits are in northwestern and far eastern Oregon.

A small natural gas field lies beneath Columbia County in the northeastern part of the state. Diatomite, which is used to make filters, is found in east-central Oregon. The state also has deposits of clays, coal, gemstones, gold, nickel, silver, and talc.

**Water** is one of Oregon's most important resources. Melted snow and winter rain from the mountains feed Oregon's rivers and provide unusually pure water for industry and home use. The Columbia River and its tributaries provide water for power and irrigation.

**Soils.** Gray-brown soils cover the Coast Range and Klamath Mountains regions. The Willamette Lowland has deep, fertile soils. Shallow soils cover most of the eastern Cascade slopes, and the Basin and Range Region. The wheat belt of north-central Oregon has rich soils good for growing crops.

**Service industries** produce the largest portion of Oregon's gross state product. These services are concentrated in the metropolitan areas.

Oregon's leading service industry is community, business, and personal services. This industry group employs more people than any other economic activity in the state. Community, business, and personal services consists of a variety of businesses, including private health care, hotels and motels, law firms, engineering companies, and repair shops. Many of the hotels and motels are along the coast and in the Portland area.

Wholesale and retail trade is the second most important service industry in Oregon in terms of contributions to the gross state product. The Port of Portland handles much wholesale trade, including the import of foreign cars and the export of wheat and forest products. Nike, one of the world's major wholesale distributors of athletic shoes and other sportswear, is based in Beaverton. Major retail establishments include department stores and food stores.

Finance, insurance, and real estate ranks third among Oregon's service industries in terms of the gross state product. Real estate is important to the state's economy because of the large amounts of money involved in the buying and selling of homes and other property. The development of retirement villages and vacation resorts is an important part of real estate. Portland is the state's main financial center. U.S. Bancorp, one of the nation's major banking companies, has many offices in Oregon.

Government ranks next among the service industries. Government services include public schools and hospitals. The University of Oregon and Oregon State University employ many people in Eugene and Corvallis. The United States Forest Service, a federal government agency, also employs many people in the state. Oregon Health Sciences University in Portland is an important center of medical research. State government agencies are based in Salem, Oregon's capital.

Transportation, communication, and utilities ranks fifth. Many shipping and trucking companies are based in Portland. Telephone companies are the major part of the communication sector. Pacificorp, the state's largest utility company, is based in Portland. This company is one of the nation's biggest providers of hydroelectric power. More information about transportation and communication appears later in this section.

**Manufacturing.** Products made in Oregon have a value added by manufacture of about $27 billion a year. This figure represents the increase in value of raw materials after they become finished products.

Electronic equipment is Oregon's leading product in terms of value added by manufacture. Many companies manufacture high-technology electronic products in the state. These products include oscilloscopes and computer monitors made by Tektronix, calculators and electronic printer components made by Hewlett-Packard, and microprocessors made by Intel Corporation.

Wood processing is the second most important manufacturing activity in the state. Oregon leads the states in lumber production. It is also a major producer of plywood, veneer, and particle board. Many parts of western Oregon have large wood-processing plants. As these plants have become more mechanized, employment in the wood products industry has declined.

Food processing ranks third among Oregon's manufacturing activities. Frozen fruits and vegetables are the leading products of this industry. Other foods produced in the state include baked goods, beverages, and canned goods.

Transportation products rank next. Important products from this sector include motor homes, ships and boats, and parts for motor vehicles and the aerospace industry.

Other goods produced in Oregon include machinery, paper products, printed materials, fabricated metal products, and primary metals. The Portland area is the
Economy of Oregon

This map shows the economic uses of land in Oregon and where the leading farm, mineral, and forest products are produced. Major manufacturing centers are shown in red.

- Mostly cropland
- Cropland mixed with grazing land and forest
- Mostly grazing land
- Forest land
- Mostly unproductive land
- Urban area
  - Manufacturing center
  - Mineral deposit

center of production for all of these goods. Oregon’s factories produce machinery for the wood products and metalworking industries. St. Helens and West Linn have mills that make paper. Commercial print shops and newspaper publishers produce a majority of the printed materials. Fabricated metals industries produce tools, hardware, and other metal items. Primary metals industries include aluminum refineries, steel mills, and companies that make metal casts and extrusions.

Agriculture. Farmland covers about 30 percent of Oregon’s land area. The state has about 40,000 farms.

Greenhouse and nursery products are the leading agricultural products in Oregon. Western Oregon is an important bulb-growing region. Farmers there grow daffodils, gladioli, irises, lilies, and tulips for bulbs.

Timber is the next most valuable agricultural product in Oregon. The most important timber trees are Douglas-fir and ponderosa pine. Douglas-fir trees grow mainly in the Cascade Mountains region and in smaller ranges west of the Cascades. Ponderosa pines grow primarily in the Blue Mountains of eastern Oregon. The state is a leading producer of Christmas trees.

Beef cattle and milk are also important agricultural products in Oregon. Most beef cattle are raised on ranges east of the Cascades. Western Oregon has many herds of dairy cattle.

Wheat is Oregon’s most valuable food crop. Most wheat grows in the plateau region of north-central Oregon near Pendleton. Hay is Oregon’s most important feed crop. Barley and oats are the state’s other major grain crops.

Oregon ranks among the top states in vegetable production. Potatoes are the leading vegetable. Large potato crops are grown on irrigated land in the far eastern part of the state. Most of Oregon’s other vegetables grow in the Willamette Valley, the state’s most diverse agricultural region. These vegetables include green peas, onions, snap beans, and sweet corn. Other west-

A tulip farm near Monitor produces flower bulbs. Farmers in western Oregon also grow daffodils, gladioli, irises, and lilies for bulbs.
ern Oregon crops include hops, which are used in making beer, and filberts (also called hazelnuts and cobnuts). The eastern part of the state produces large sugar beet crops.

Oregon is among the leading states in the production of berries, pears, plums, and sweet cherries. The Hood and Rogue river valleys are famous pear-growing regions. North-central Oregon leads the state in cherry production. Berries and plums are grown mainly in the northwestern part of the state. Apples are grown in the Hood River Valley.

Oregon farmers specialize in several crops that are not grown widely in many other states. For example, Oregon produces almost all the nation's seed for bentgrass, fescue, ryegrass, crimson clover, Kentucky and merion bluegrasses, and orchardgrass. These crops are grown mainly in Willamette Valley counties. Oregon is also a leader in the production of peppermint oil.

Douglas County, in southwestern Oregon, leads the state in sheep raising. Sheep also graze on the eastern ranges and the Willamette Valley grasslands. Willamette Valley farmers raise most of the state's chickens. Umatilla County is the leading hog producer.

**Mining.** Two mined products—(1) sand and gravel and (2) stone—provide about three-fourths of Oregon's mining income. These products, used mainly for road construction, are mined in several regions of the state. Oregon is a leading state in the production of pumice. Other products mined in Oregon include clays, diatomite, gold, and semiprecious gems.

**Fishing industry.** Oregon has an annual fish catch valued at about $70 million. Albacore tuna, crab, shrimp, and whiting are among the state's leading catches.

**Electric power.** Hydroelectric plants supply the vast majority of Oregon's electric power. Most of the state's hydroelectric power comes from dams that stand on the Columbia River between Oregon and Washington. They include Bonneville, John Day, McNary, and The Dalles. The rest of the state's hydroelectric power is generated at dams on rivers entirely within Oregon. These rivers include the Deschutes, Willamette, and Rogue. Oregon's large supply of hydroelectric power makes its electric rates among the least expensive in the nation. Plants that burn coal or natural gas supply small amounts of the state's power.

**Transportation.** From 1841 to the coming of the railroads in the 1860's, thousands of people traveled the famous Oregon Trail to Oregon (see Oregon Trail). Today, Oregon has about 97,000 miles (156,000 kilometers) of roads. About 20 rail lines provide freight service. Passenger trains serve several Oregon cities.

Portland International Airport is one of the major airports in the western United States. Oregon's next busiest airports are in Eugene and Medford.

Portland is a major ocean port, though it is about 100 miles (160 kilometers) inland. Oceangoing ships follow a deepened channel up the Columbia and into the Willamette River to reach Portland's harbor. Oregon's other major ports are Coos Bay and Astoria.

**Communication.** Oregon's first newspaper, the Oregon Spectator, began publication at Oregon City in 1846. It is no longer published. The Oregonian was established in Portland in 1850 as the Weekly Oregonian. The Oregon Statesman (now the Statesman Journal) appeared in Oregon City in 1851 and later moved to Salem. These two papers are still published today. Other leading daily newspapers in Oregon include the Mail Tribune of Medford and The Register-Guard of Eugene. Oregon has about 120 newspapers, including about 20 daily newspapers. Oregon publishers also issue about 100 periodicals.

Oregon's first commercial radio station, KGW, opened in Portland in 1922. Its first television station, KPTV, began operating in Portland in 1952. Oregon has about 160 radio stations and 20 TV stations. Cable TV systems and Internet providers serve many communities statewide.
**Constitution.** The present state Constitution was adopted in 1857, two years before Oregon joined the Union. Constitutional amendments may be proposed by either house of the state legislature. A majority of the members of each house must approve the amendments. Voters must then approve the amendments in the next regular general election, unless the legislature orders a special election.

Amendments to the Constitution of Oregon may also be proposed and passed directly by the people, through their powers of initiative and referendum (see Initiative and referendum). The Constitution may also be revised by a constitutional convention. A convention may be called after a majority of legislators and voters give their approval.

**Executive.** Oregon voters elect the governor to a four-year term. The governor has the power to appoint members of many state boards and commissions. Other top state officials include the attorney general, commissioner of labor and industries, secretary of state, superintendent of public instruction, and treasurer. These officials are also elected to four-year terms.

**Legislature** is called the Legislative Assembly. It consists of a Senate of 30 members and a House of Representatives of 60 members. The state has 30 senatorial districts and 60 representative districts. Voters in each senatorial district elect one senator. Voters in each representative district elect one representative.

State senators serve four-year terms, and representatives serve two-year terms. The Assembly meets in regular session in odd-numbered years. Legislative sessions usually begin on the second Monday in January. There is no limit to a session’s length.

**Courts.** The highest court in Oregon is the state Supreme Court. It has seven justices elected to six-year terms. The court elects one of its members to serve a six-year term as chief justice. The next highest state court is the court of appeals. It has 10 judges who are elected to six-year terms.

Oregon is divided into 19 judicial districts. Each judicial district has one or more circuit court judges. Voters elect the circuit court judges to six-year terms by nonpartisan (no-party) ballot.

A special tax court ranks with the circuit courts. Lower courts in Oregon include district, county, justice, and municipal courts.

**Local government.** Oregon gives its cities and towns home rule. This means they have the right to choose their own form of government. Most cities with more than 5,000 people have the council-manager form.
of government. Portland has a mayor and four commissioners. Most of Oregon's smaller cities have a mayor and a city council.

A 1958 amendment to the state Constitution extended home rule privileges to Oregon counties. However, only 8 of the state's 36 counties have taken action under this law. A three- or five-member board of commissioners governs most counties in Oregon. In most cases, the county commissioners are elected to four-year terms.

Revenue. Taxes account for about half of the state government's general revenue (income). Other sources of revenue include bond sales, charges for government services, and grants from the federal government. The most important source of tax revenue is a personal income tax. Other major sources of tax revenue are taxes on motor fuels, motor vehicle licenses, corporate income, and tobacco products. The state also receives revenue from a lottery. Oregon has no state sales tax.

Politics. The Republican Party controlled Oregon politics during most of the state's history. Many industrial workers who settled in Oregon cities after World War II caused changes in the state's politics. In the mid-1950's, registered Democrats began to outnumber registered Republicans.

The legislative districts have been changed periodically, beginning in the 1960's. These actions have given more representation to urban areas, where the Democrats have their greatest strength. Since the early 1970's, both Democratic and Republican candidates have won election to the highest state offices. For Oregon's voting record in presidential elections since 1860, see Electoral College (table).

History

Indian days. When the first white people entered the Oregon region, many Indian tribes lived there. The Chinook lived along the lower Columbia River, where they fished for salmon. The Clackama, Kalapuya, Multnomah, and Tillamook tribes also made their homes in the northwest. The Bannock, Cayuse, Paiute, Umatilla, and a major band of the Nez Perce lived east of the Cascade Mountains. The Klamath and the Rogue lived near the present-day border with California.

Exploration and settlement. Spanish explorers sailing north from Mexico in 1543 were the first white people to see the Oregon coast. Sir Francis Drake of England may have seen Oregon's southern coast in 1579 while searching for a water route between the northern Pacific and Atlantic oceans.

In 1778, British explorer James Cook sailed to Yaquina Bay and named Cape Foulweather as he went north. In 1788, the first American ships arrived off the Oregon coast, including one led by Captain Robert Gray. In May 1792, Gray became the first to sail into the Columbia River, which he named for his ship. A few weeks later, Captain George Vancouver of Britain, who was exploring the Northwest coast, sent William Broughton, one of his lieutenants, into the Columbia. Broughton probably sailed as far as the Sandy River, east of present-day Portland, and named such landmarks as Mount Hood and Mount St. Helens. The explorers Meriwether Lewis and William Clark reached the mouth of the Columbia by land in 1805. The Lewis and Clark expedition, together with Gray's trip on the Columbia River, gave the United States a strong claim to the Oregon region.

In the early 1800's, the Oregon region stretched from Alaska, which was claimed by Russia, to California, which was claimed by Spain. It extended eastward from the Pacific Ocean to the Rocky Mountains. Russia, Spain, Britain, and the United States claimed parts of the region. Russia based its claims on Russian explorations along the northern Pacific Coast. In treaties with Britain and the United States in 1824 and 1825, Russia gave up its interests south of latitude 54°40'. In 1819, by treaty, Spain gave up its claim north of latitude 42°, Oregon's present southern boundary. Britain and the United States could not agree on a boundary line. They signed a treaty in 1818 that permitted citizens of both countries to trade and settle in the region. The treaty was renewed in 1827.

John Jacob Astor, an American fur trader, began the white settlement of Oregon. His company, the Pacific Fur Company, set up a fur-trading post at Astoria in 1811. But the North West Company, a British fur company, gained possession of Astoria in 1813 during the War of 1812. In 1821, the company merged with the Hudson's Bay Company, another British trading firm. This firm founded Fort Vancouver (now Vancouver, Washington) in 1825. John McLoughlin guided the activities of the Hudson's Bay Company and ruled the region for about 20 years. He later became a U.S. citizen. McLoughlin played a leading part in settling the region. Today, he is known as the father of Oregon.

In 1834, Methodist missionaries established the first permanent American settlement in the Willamette Valley. The first large overland migration into Oregon came in 1843. That year, about 900 people traveled the Oregon Trail and settled in the Willamette Valley. Hundreds of American settlers arrived each year from then on. The increasing number of settlers put pressure on the U.S. government to settle the boundary dispute with Britain. In 1844, James K. Polk based his campaign for the presidency partly on the claim that land south of latitude 54°40' belonged to the United States (see Fifty-Four Forty or Fight). In 1846, President Polk signed a treaty with Britain. It fixed the 49th parallel as the chief dividing line between United States and British territory.

Indian wars. In 1847, Indians massacred Marcus Whitman and 13 others, near present-day Walla Walla, Washington (see Whiteman, Marcus). This massacre led to the Cayuse War of 1847-1848. It also resulted in the execution in 1850 of five Cayuse Indians held responsible for the massacre. The discovery of gold in southwest Oregon during the early 1850's led to a series of conflicts between white miners and the Rogue Indians. The resulting Rogue River Indian War ended in 1856 with the removal of the Indians to a reservation on the central coast of Oregon.

One of the major Indian wars, the Modoc War, lasted from November 1872 to May 1873. The U.S. government
Captain Robert Gray visited the Oregon country in 1792. He sailed into the mouth of a great river that he named after his ship, the Columbia.

Astoria was founded by John Jacob Astor's Pacific Fur Company in 1811. The fur-trading post was the first white settlement in the Oregon region.

John McLoughlin, the director of the Hudson's Bay Company in the Oregon region from 1824 to 1846, helped many settlers. He is known as the father of Oregon.

Settlers traveled west on the Oregon Trail from Independence, Mo., to the Willamette Valley during the 1840's. The Oregon Territory was created in 1848.

Important dates in Oregon

1579 Sir Francis Drake possibly touched the Oregon coast.
1792 Robert Gray sailed into the Columbia River.
1805 Meriwether Lewis and William Clark reached the mouth of the Columbia.
1811 John Jacob Astor founded Astoria.
1819 A treaty between the United States and Spain fixed the present southern border of Oregon.
1843 The Willamette settlers at Champoeg organized a provisional government.
1846 A treaty made the 49th parallel the chief boundary between British and U.S. territory in the Oregon region.
1848 Oregon became a territory.
1850 Congress passed the Oregon Donation Land Law.
1859 Oregon became the 33rd state on February 14.
1902 Oregon adopted the initiative and referendum.
1912 The state adopted woman suffrage.
1937 Bonneville Dam was completed.
1950's McNary and The Dalles dams were built on the Columbia River.
1964 Heavy floods damaged western Oregon.
1982 Construction was completed on a second powerhouse at Bonneville Dam.
1991 Barbara Roberts became Oregon's first woman governor. She held office until 1995.
forced the Modoc Indians onto the Klamath Reservation. But the Modoc fled from the reservation and hid near the California border among lava beds, which provided a natural fortress. A small band of warriors kept more than a thousand U.S. soldiers at bay until the Indians finally surrendered.

The Nez Perce War occurred in 1877. That year, the government ordered several Nez Perce bands to move from their traditional lands in the beautiful Wallowa Valley and other areas to a reservation in Idaho. Some bands resisted. One group, led by Chief Joseph, tried to escape through Idaho and Montana. Joseph and over 400 Nez Perce finally surrendered near the Canadian border. The Paiute and Bannock Indians rose against Oregon settlers in 1878, but were quickly defeated. See Indian wars (In California and the Northwest).

**Provisional and territorial governments.** In 1843, settlers in the Willamette Valley met at Champoeg (near present-day Newberg) and organized a provisional government. The settlers adopted a set of laws which were based on the laws of Iowa.

Oregon became a territory in 1848, and Oregon City was proclaimed the territorial capital in early 1849. The legislature moved to Salem in 1851. Oregon's present boundaries were drawn in 1853, when Congress created the Washington Territory.

The Donation Land Law of 1850 spurred territorial growth and development. This law provided that any male American citizen over 18 who settled in Oregon before December 1850 could receive 320 acres (129 hectares) of land. His wife could also receive 320 acres of her own. To qualify for ownership, a man had to cultivate his claim for four years. From December 1850 to December 1855, a settler had to be at least 21 to receive land, and he got only 160 acres (65 hectares). A settler's wife could receive the same amount.

**Progress as a state.** Oregon joined the Union as the 33rd state on Feb. 14, 1859. Salem became the state capital. During the Civil War (1861–1865), state volunteers protected eastern Oregon against Indian attacks. The attacks continued for 15 years after the war. The population increased rapidly after the war as former soldiers sought opportunities in the West. The population grew from about 52,000 in 1860 to over 300,000 by 1890. Much of this increase occurred during the 1880s after the arrival of the transcontinental railroads.

**The early 1900's.** In 1902, Oregon adopted the *initiative and referendum*, procedures that permit voters to take a direct part in lawmaking (see Initiative and referendum). In 1908, it adopted the *recall*, a procedure for removing undesirable officials from office. The use of these direct-government procedures became known as the *Oregon system*. Many states have passed initiative, referendum, and recall laws based on this system.

In 1912, Oregon gave women the right to vote for the first time in the state's history. Passage of the law followed a long and difficult campaign for women's rights led by Abigail Jane Scott Dunway.

During the Great Depression of the 1930's, the federal government provided money to build Bonneville Dam on the Columbia River. The dam and nearby locks supplied electric power for industry and improved the river for navigation. Owyhee Dam, which was completed in 1932, provided irrigation water for vast areas of farm-land in the Owyhee and Snake river valleys.

**The mid-1900's.** By 1940, Oregon's population had grown to more than a million. During World War II (1939–1945), many of the state's factories produced military equipment. Portland became a major port for shipment of supplies to the Soviet Union and to U.S. armed forces in the Pacific. The city's shipyards produced cargo vessels and warships. Thousands of people from other states came to work in Oregon defense plants, and many of them settled in the state after the war.

During the 1950s, McNary and The Dalles dams were built on the Columbia River and greatly increased Oregon's supply of low-cost electric power. In 1956, pipelines brought natural gas into the state. Both developments contributed greatly to Oregon's industrial growth. Many people began to move from rural to urban areas to take manufacturing jobs.

Important changes took place in the Oregon timber industry during the 1960s. In the past, sawdust, bark, and other logging by-products had been wasted. Now, Oregon companies began to use many of these materials to make hardboard, pulp, and other wood products. Forestry specialists discovered new uses for forest products and studied ways to conserve the state's timber reserves. The industry replanted an increasing number of trees to replace those that had been cut down.

Changes also occurred in Oregon agriculture. The state's farms became larger and more closely linked with food processing. Farmers used more and more machinery. Irrigation projects allowed farmers to grow fruits and vegetables on land that once had been too dry for any crops except grasses.

Low-cost hydroelectric power from dams on the Columbia and Willamette rivers helped Oregon's economy grow during the 1960s. Industries, including the manufacture of electrical equipment, machinery, and metals, grew in importance.

The worst floods in Oregon's history hit in 1964. They caused millions of dollars of damage, killed several people, and forced thousands from their homes.
The late 1900s. Completion of a number of dams on the Columbia and Snake rivers in the early 1970s provided deepwater transportation from the mouth of the Columbia to Lewiston, Idaho. These dams also increased the hydroelectric power capacity in Oregon. The power output of Bonneville Dam, the first federal dam constructed on the Columbia River, was more than doubled in 1982 when construction of a second powerhouse was completed.

In the early 1980s, Oregon experienced its worst economic crisis since the Great Depression. A widespread decline in housing and construction led to hard times in the lumber, wood processing, and construction industries. Many Oregon lumber mills closed, and many jobs were lost in the wood and construction industries. Low prices for farm products, including wheat and dairy and livestock products, contributed to the crisis.

Improvements in Oregon's economy began in the mid-1980s and continued in the 1990s. Some of the lumber mills that had closed reopened. The electronics industry became important, although employment in trade and other service industries grew more rapidly than jobs in manufacturing. Expansion of the fruit, grass seed, nursery, nut, and wine industries also improved economic conditions.

In 1991, Barbara Roberts became Oregon's first woman governor. She served until 1995.

Claude W. Curran and Gordon B. Dodds

Oregon, University of, is a state-assisted coeducational school in Eugene, Oregon. The university has a college of arts and sciences; professional schools of architecture and allied arts, business administration, education, human development and performance, journalism, law, and music; and a graduate school. It also has interdisciplinary programs in the natural sciences, international affairs, and environmental affairs. Programs of study lead to bachelor's, master's, and doctor's degrees. The university has museums of art and of natural history. The University of Oregon was chartered in 1872 and opened to students in 1876.

Critically reviewed by the University of Oregon

Oregon grape is the state flower of Oregon. This wild plant, also called the Oregon holly grape, grows from western Oregon through Washington into British Columbia. Despite its names, the Oregon grape is neither a grape nor a holly. It grows to 2 feet (61 centimeters) tall and does not climb as the wild grape does. The leaves look like those of the holly, and the wood is yellow. Clusters of yellow flowers open in early summer. The
berries ripen in the fall. They look like grapes or blueberries and are often used for jelly. See also Barberry; Oregon (picture: State flower).  

Fred T. Davies, Jr.

Scientific classification. The Oregon grape is in the barberry family, Berberidaceae. Its scientific name is Mahonia nervosa.

Oregon State University is a state-supported, coeducational school in Corvallis, Oregon. It includes colleges of agricultural sciences, business, engineering, forestry, health and human performance, home economics, liberal arts, oceanography, pharmacy, science, and veterinary medicine. It grants bachelor's, master's, and doctor's degrees. The university operates an extension service and agricultural experiment stations. It also has research vessels and a marine science center in Newport, Oregon. The school was founded in 1868.

Critically reviewed by Oregon State University.

Oregon Territory was created after the settlement in 1846 of a boundary dispute between the United States and the United Kingdom. It included the present states of Idaho, Oregon, and Washington and part of Montana and Wyoming. Before 1846, the Oregon Country, occupied jointly by the United States and the United Kingdom, included the area south of Alaska, north of California, and west of the Rocky Mountains. The 1846 settlement gave the United States the land south of the 49th parallel, except for Vancouver Island. The Oregon Country became a territory in 1848. Oregon was admitted to the Union on Feb. 14, 1859.

Jerome O. Steffen

Oregon Trail was the longest of the great overland routes used in the westward expansion of the United States. It wound 2,000 miles (3,200 kilometers) through prairies and deserts and across mountains from Independence, Missouri, to the Pacific Northwest. Even today, travelers can see the deeply rutted road cut by wagon wheels along sections of the trail.

Families traveling to the Oregon region usually began their journey at Independence, near the Missouri River. They followed a trail that ran northwest to Fort Kearny, Nebraska. Then they traveled up the Platte River and its north branch to Fort Laramie, Wyoming. From this point, they continued along the North Platte to its Sweetwater branch, and crossed through South Pass in the Rocky Mountains to the Green River Valley at Fort Bridger, Wyoming. The route turned northwest to Fort Hall in the Snake River area, and on to Fort Boise, Idaho. Settlers crossed the Grande Ronde Valley and the Blue Mountains to Marcus Whitman's mission at Walla Walla, Washington. Then they went down the Columbia River to Fort Vancouver and the Willamette Valley of Oregon.

Travel on the Oregon Trail was a severe test of strength and endurance. The journey in a covered wagon took six months. Settlers often had to cross flooded rivers. Indians attacked the wagon trains, and cholera and other diseases were common. Food, water, and wood were always scarce, and the travelers often encountered contaminated water holes.

Explorers and fur traders first traced the course of the Oregon Trail. In 1805, Meriwether Lewis and William Clark traveled on a western section of the route in the region of the Snake and Columbia rivers. Traders returning from Astoria also used the trail. Benjamin Bonneville is credited with taking the first wagons through South Pass in the 1830s. Nathaniel J. Wyeth also led companies over the trail. John C. Fremont surveyed a portion of the route in 1842 for the United States Army.

Settlers began following the trail to Oregon in 1841. The first large group, about 900, used the trail in the "Great Migration" of 1843. In that year, a provisional government was organized. The Oregon Country's northern boundary was set in 1846, and the Territory of Oregon was set up in 1848.

O'Reilly, Leonora (1870-1927), was an American labor leader and reformer. She became well known as a lecturer and union organizer. O'Reilly strongly supported vocational training for girls.

O'Reilly was born in New York City and went to work in a shirt collar factory at the age of 11. In 1897, she helped organize a local garment workers' union. From 1902 until 1909, O'Reilly taught at the Manhattan Trade School for Girls, where she developed a strong belief in vocational education.

In 1903, O'Reilly helped establish the National Women's Trade Union League. This group promoted laws to protect the rights of women factory workers and aided the growth of women's labor unions. In 1909, O'Reilly helped lead a strike in New York City by the International Ladies' Garment Workers' Union. Thousands of workers won wage increases after the five-month strike.

O'Reilly helped found the National Association for the Advancement of Colored People (NAACP) in 1909. She also was active in the Woman Suffrage Party and the Socialist Party.

Orellana, oh ray L Yah nah, Francisco de [1511?-1546], a Spanish explorer, headed the first group of Europeans to navigate the entire length of the Amazon River in South America. In March 1541, he joined a Spanish expedition traveling eastward from Quito in what is now Ecuador. The expedition was led by Gonzalo Pizarro, a half brother of the Spanish explorer and conqueror Francisco Pizarro. The Spaniards soon began to starve and become sick. In December 1541, Orellana and about 55 other men set out by boat on a tributary of the Amazon River in search of food, but they never returned. Instead, they sailed to the Atlantic Ocean, which they reached in August 1542. Some historians consider Orellana a traitor for abandoning Pizarro. In 1544, Orellana was named governor of the territory he had explored. See Amazon River (History). Helen Delpar

Orestes. See Electra; Iphigenia.

Orff, Carl (1895-1982), was a German composer and music educator. His major works were for the stage. They combine instrumental music, singing, and gesture and dance into a unified spectacle. Orff's music emphasizes simple, folklike melodies and harmonies that are sometimes colored with dissonance. He used instruments percursoriously to create a powerful rhythmic drive. Orff used Oriental and medieval scales and texts in several languages, sometimes simultaneously.

Orff's best known compositions are three pieces he called Triológi Triumphi! The first, and most popular, Carmina Burana (Songs of Beuron, 1937), consists of songs set to medieval texts. He used poems by the Roman poet Catullus as texts in Catulli Carmina (Songs of Catullus, 1943). In Triumph di Afrodite (The Triumph of Aphrodite, 1953), Orff adapted texts by Catullus and the ancient Greek writers Sappho and Euripides.

Orff was born in Munich. In 1924, he cofounded a school of gymnastics, music, and dance in Munich. His work at the school reflected his interest in musical education for children. Orff summed up his theories in an important five-volume book called Music for Children (1930-1934, revised 1950-1954). Daniel T. Politzko

Organ. See Human body.

Organ is a keyboard musical instrument. There are two chief kinds of organs, pipe organs and electronic organs. Most pipe organs are found in churches, concert halls, and theaters. The history of the pipe organ can be traced back more than 2,000 years. Many masterpieces of music have been composed for it.

The electronic organ was invented in the 16th-1900's. Most performers consider the pipe organ superior to the electronic organ. However, electronic organs are popular instruments in the home, and many churches also have them. The electronic organ ranks behind only the piano and the guitar as the most widely played instrument in the United States.

Both the pipe organ and the electronic organ have one or more keyboards that resemble a piano keyboard. However, the instruments produce sounds differently. A piano makes sounds by causing steel strings to vibrate. A pipe organ creates sounds by forcing air through metal or wooden tubes called pipes. An electronic organ produces sounds by means of electricity.

A pipe organ is the largest and most powerful of all musical instruments. Many pipe organs are so large that they must be built as part of the building where they are to be used. A large pipe organ can produce effects of grandeur that even a symphony orchestra cannot duplicate. It also can play delicate and refined music.

Pipe organs. A small pipe organ has only a few hundred pipes, but a large organ has more than 5,000 pipes. Most pipes are made of lead or of lead mixed with tin. Some are made of other metals or wood.

An organist creates music by combining the sounds of different ranks (rows) of individual pipes. Each pipe in a rank is tuned to a single pitch and produces only one musical tone. Some ranks are pitched one or two octaves higher or lower than others.

---

How a pipe organ works

---

This diagram shows how wind flows through a pipe organ. An electric motor provides power for most modern organs. It operates a fan that forces wind into an air reservoir. The wind moves through a wind trunk into a wind chest. When a key is pressed, a pallet opens and wind enters the key channel. From there a slider, controlled by a stop knob, allows wind to flow into the pipes. As the wind passes through a pipe, it produces a note.
Most organs have two types of pipes—flue pipes and reed pipes. A flue pipe works like a simple whistle. Air enters from a hole in the bottom of the pipe and causes a column of air inside the pipe to vibrate. The vibration creates the sound. A reed pipe contains a thin brass reed that vibrates as air passes around it.

About 80 percent of the pipes in an organ are shaped like cylinders. But no two pipes of an organ look or sound exactly alike. The shape and size of the pipe determines the sound it makes. The longest pipes, which produce the lowest notes, may be more than 30 feet (9 meters) long and 1 foot (30 centimeters) in diameter. But most pipes measure less than 4 feet (1.2 meters) long. The smallest pipes, which produce the highest notes, are only 7 inches (18 centimeters) long and less than \( \frac{1}{4} \) inch (6 millimeters) in diameter.

Most pipe organs have one, two, or three keyboards. A few have as many as six. The additional keyboards enable the organist to create a wide variety of musical effects. The keyboards played with the hands are called manuals. Large organs may have up to five manuals called, in order of importance, the great organ; swell organ; positive, or choir, organ; solo organ; and echo organ. Most organs also have a pedalboard, a keyboard played with the feet. Each keyboard—manuals and pedalboard—operates a number of ranks. Every key controls several pipes. All the ranks operated by a keyboard are arranged on a wind chest, a box that receives an even flow of wind from a reservoir. An electrically powered fan fills the reservoir with wind.

A thin strip of plastic or wood called a slider lies under each rank of pipes on a wind chest. A slider has holes in it that match the number and size of the holes in the rank of pipes above it. A slider regulates the passage of wind into the pipes. Sliders are controlled by stop knobs, commonly called stops, near the manuals. By pulling a stop, the organist moves the slider into position beneath the pipes so that wind can enter them.

To let wind into certain pipes, the organist presses the key that controls those pipes. This action opens a valve called a pallet in the wind chest and allows wind to flow into a compartment called the key channel. Wind enters the pipes from the key channel.

A cabinet called a case encloses all the pipes on a wind chest. It blends the sounds of the pipes and projects this combination of sound out of the organ.

Electronic organs have no pipes. Devices called oscillators generate an electric current that produces the tones. The organ's sound is amplified electronically. An electronic organ cannot create the variety and richness of sound that a pipe organ can. But it costs less and requires less space. The electronic organ has become a popular instrument in the home. It is also widely used in jazz and rock music. The synthesizer is a modern keyboard instrument capable of imitating the sounds of many other instruments. See Synthesizer.

History. In the 200s B.C., Ctesibius of Alexandria, a Greek engineer, built an organ that was called a hydraulus, or hydraulis. This organ used water power to force air into the pipes. Organs that used a bellows first appeared in Byzantium (now Istanbul, Turkey) during the A.D. 100s and 200s. The major features of the modern organ were developed from the 200s to the 1500s. The keyboard was developed by the end of the 1400s.

From the 1500s to the mid-1700s, many composers wrote organ masterpieces. The greatest of these composers was Johann Sebastian Bach of Germany. Other leading organ composers included François Couperin of France and Girolamo Frescobaldi of Italy. During this period, organists accompanied singers in operas and in oratorios. Large organs were played in churches. Small organs were popular at home and at public events.

By the late 1700s, small organs had lost their popularity. Many composers believed an orchestra or a piano could provide a wider range of musical effects. By 1900, interest in the organ had declined among composers and performers. The instrument was played regularly only in churches as part of religious services. A revival of interest in the organ began during the early 1900s. The German humanitarians Albert Schweitzer, an accomplished organist, began this revival. He gave concerts in many European cities and stimulated interest in the instrument. In 1934, Laurens Hammond, an American inventor, patented the first commercially practical electronic organ. Dale C. Carr

Organ donation is the process through which human organs are obtained for transplant surgery. Most organs used in transplant operations come from young, otherwise healthy patients who suffer brain death (the permanent end of brain function), often following a fatal head injury. Organs commonly transplanted from one person to another include the heart, kidney, liver, and lung.

Advances in organ transplant surgery and powerful drugs to prevent organ rejection have made transplants an established medical treatment for many diseases and injuries. Organ donation can save lives and restore health, and most major religions permit such donations. The supply of human organs falls far short of the demand, however. As a result, medical professionals must make difficult ethical decisions to obtain human organs and assign them to people in need of transplants.

In most countries, doctors must obtain permission to remove organs from the dead to use for transplant. In the United States and the United Kingdom, people can use donor cards or mark a space on their driver's license to give permission to donate their organs after death. In practice, however, many hospitals consult the family even if the patient has signed an organ donor card. In Australia, donor permission is required, but final approval must come from family. In some other countries, including Austria and Belgium, doctors may remove organs for transplant after death unless there is written evidence that the person does not want to be a donor. This system, called presumed consent, increases the supply of human organs available for transplant. But under such a system, some people who would not want to donate their organs might become donors.

Medical professionals are investigating ways to increase the supply of human organs for transplant, including increasing live donation and compensation for organ donors. More than one-third of transplanted kidneys in the United States come from live donors, because a person can donate one kidney and remain
healthy. Live liver donation, where a lobe of the donor's liver is transplanted and grows into a fully functioning organ, is also becoming more common. Most living organ donors are close relatives of the recipient, but about 20 percent of live organ donations involve unrelated people.

In the United States, the National Organ Transplant Act of 1984 prohibits the exchange of organs for any kind of payment. However, lawmakers are considering legislation that allows compensation to donors to encourage more live organ donations.

See also Transplant.

Organic chemistry is the study of compounds that contain carbon atoms. Carbon atoms are unusual because they can form chemical bonds in many different ways, both with other carbon atoms and with other chemical elements. As a result, many kinds of carbon-containing compounds are possible. Scientists have identified several million organic compounds.

A large number of simple organic compounds are obtained from plant and animal sources. For example, petroleum and natural gas contain many hydrocarbons from the remains of organisms that lived millions of years ago. Ethanol, a kind of alcohol, is formed by the fermentation of fruits, grains, and vegetables. Other organic compounds in living matter include amino acids, sugars, and nucleic acids. Inorganic compounds, which generally do not contain carbon, occur chiefly in rocks and in minerals.

Scientists once believed that carbon-containing compounds could be obtained only from living sources. However, in 1828, the German chemist Friedrich Wöhler prepared the organic compound urea in his laboratory. Since then, scientists have found many ways of making organic compounds from both organic and inorganic materials, and many important new compounds have been prepared in the laboratory. These compounds include medicines, insecticides, and chains of molecules called polymers (see Polymer). Robert C. Gadwood

See also Chemistry.

Organization for Economic Cooperation and Development is an association of 30 nations in Europe, North America, and the Pacific area. The organization, called the OECD, works to promote the economic and social welfare of its members, and coordinates their efforts to aid developing countries. The OECD was established in 1961 to succeed the Organization for European Economic Cooperation (OEEC). Seventeen European nations formed the OEEC in 1948 as a result of the Marshall Plan. Under the Marshall Plan, the United States helped Europe achieve economic recovery after World War II (1939-1945). The OECD's headquarters are located in Paris. See also International Energy Agency.

Critically reviewed by the Organization for Economic Cooperation and Development

Organization for Security and Cooperation in Europe is an international association of more than 50 Eastern and Western countries that work to increase their security. The organization is sometimes called the OSCE. Until 1995, it was called the Conference on Security and Cooperation in Europe (CSCE).

The OSCE's members are Russia and all the other nations of Europe, plus the United States, Canada, and the central Asian countries that were once part of the Soviet Union. Members include all countries of the North Atlantic Treaty Organization (NATO) as well as the lands that once belonged to the Warsaw Pact. NATO is a non-Communist defense alliance, and the Warsaw Pact was a Communist one. The two alliances were intense rivals during the Cold War, a period of hostility that developed between the Communist and non-Communist nations after World War II ended in 1945. The Warsaw Pact, led by the Soviet Union, was dissolved in 1991.

The first of many CSCE conferences met in 1975 in Helsinki, Finland. That conference produced the Helsinki Accords. In the accords, Western countries finally recognized Eastern European boundaries that had been set up after World War II. The accords also stimulated the formation of human rights groups that later helped overthrow many Communist governments in Eastern Europe and the Soviet Union. In 1990, a CSCE conference in Paris declared an end to the Cold War. The Paris conference also established a CSCE secretariat in Prague, in what is now the Czech Republic; a conflict-resolution center in Vienna, Austria; and in Warsaw, Poland, an office to monitor elections in European countries.

The Soviet Union belonged to the CSCE until 1991, when the country broke up into a number of independent states. After the breakup, Russia assumed the Soviet seat, and all the other states that had been part of the Soviet Union eventually joined the CSCE.

In 1992, the CSCE acquired the authority to send peacekeeping forces to its member nations. It also agreed to oversee the negotiation of arms-control agreements between its Eastern and Western members.

Joseph Preston Baratta

See also Helsinki Accords.

Organization of African Unity (OAU) was an association of African states. It existed from 1963 until 2002, when it was replaced by the African Union (see African Union). The OAU played a large role in helping end colonial and white minority rule throughout Africa. It also worked to strengthen cultural, economic, military, and scientific ties among African peoples.

The OAU was founded in 1963 in Addis Ababa, Ethiopia, with 32 members. Its membership grew to include 52 countries and a government-in-exile. The OAU settled several boundary disputes between African states. It helped support national independence movements in countries such as Mozambique and Angola, as well as movements to end white minority control of Rhodesia (now Zimbabwe) and South Africa. It supported ambitious programs for economic development and cooper-
atation throughout Africa. The OAU also worked to increase Africa's influence in world affairs.

Despite its accomplishments, the OAU experienced many problems. For example, Morocco and other countries disputed the decision to admit the Saharawi Arab Democratic Republic (SADR) as an OAU member in 1982. The SADR is a government-in-exile that was formed by people seeking independence for Western Sahara, a territory claimed by Morocco. When the SADR took its seat in 1984, Morocco withdrew from the OAU. The organization's other problems included the failure of many countries to pay dues on time and difficulties in coping with armed conflicts between and within countries. In addition, larger countries often pursued their own interests rather than the interests of the OAU.

In 2000, OAU leaders signed an act creating an African Union, with a structure similar to that of the European Union (see European Union). The African Union officially replaced the OAU in 2002. The union's purpose is to continue the political and economic integration of Africa that was begun by the OAU. —Mammo Muchie

Organization of American States (OAS) is an association of 35 American countries. It seeks to provide for collective self-defense, regional cooperation, and the peaceful settlement of controversies. The OAS charter sets forth the group's guiding principles. These principles include a belief in the value of international law, social justice, economic cooperation, and the equality of all people. The OAS charter also states that an act of aggression against one American nation is regarded as an act of aggression against all the nations in the OAS.

The OAS functions through several bodies. Major policies are formed at annual sessions of the General Assembly. All member nations can attend, and each has one vote. Special Meetings of Consultation of Ministers of Foreign Affairs deal with urgent problems, especially those relating to defense or the maintenance of peace in the Americas. The Permanent Council, with headquarters in Washington, D.C., is the executive body of the OAS. Each member nation is represented. For convenience, diplomatic representatives in Washington serve as council members. The council supervises the General Secretariat, makes plans for General Assembly sessions, and oversees OAS administration. The secretary-general, the chief administrator of the OAS, is elected to a five-year term by the General Assembly. Specialized conferences promote inter-American cooperation.

The Organization of American States had its early beginning at the First International Conference of American States, which met in Washington, D.C., in 1889 and 1890. The delegates established the International Union of American Republics, with the Commercial Bureau of the American Republics as its central office. This bureau was renamed the Pan American Union in 1910. The Pan American Union became the permanent body of the OAS when it was organized in 1948 at the ninth Pan-American Conference, held in Bogotá, Colombia. The organization's original charter became effective in December 1951. An amended charter took effect in February 1970, and the Pan American Union was renamed the General Secretariat of the OAS.

Early in 1962, the Organization of American States voted to exclude Cuba's Communist government from active membership. But Cuba itself remains an OAS member even though its government cannot participate in any of the organization's activities.

In 1965, a revolt in the Dominican Republic led the OAS to set up its first military force. Troops from six Latin American countries and the United States took part. The troops and OAS committees worked to restore order in the Dominican Republic. In 1969, the OAS acted quickly to end a five-day invasion of Honduras by troops from El Salvador.

During the late 1970's, the organization's main concern became human rights. The Inter-American Human Rights Commission—a specialized OAS agency—interviewed political exiles and conducted on-site investigations of human-rights violations. The commission also issued reports about electoral fraud, illegal imprisonment, and torture and other acts of brutality.

The influence of the OAS began to decline during the early 1980's because of increased involvement by other international agencies in Latin American affairs. These agencies included the International Monetary Fund and the World Bank. —George W. Grayson

See also Pan-American conferences.

Organization of the Petroleum Exporting Countries (OPEC) is an association of 11 nations that depend heavily on oil exports for their incomes. Its members work together to try to increase their revenue from the sale of oil on the world market. OPEC members produce about 40 percent of the world's oil and possess about 75 percent of the world's recoverable oil reserves.

The members of OPEC are Algeria, Indonesia, Iran, Iraq, Kuwait, Libya, Nigeria, Qatar, Saudi Arabia, the United Arab Emirates, and Venezuela.

OPEC was founded in 1960 by Iran, Iraq, Kuwait, Saudi Arabia, and Venezuela. At that time, the petroleum industry in these countries was controlled by United States and European oil companies. These firms paid the host governments income taxes and royalties (shares of their profits) based on the posted price the companies charged for crude oil on the world market. In 1959 and 1960, oil production greatly exceeded world demand. The surplus that was thereby created prompted several of the major companies to cut the posted price and thus their payments to host governments. OPEC was founded in response to this price cut.

OPEC had little influence on oil prices during the 1960's, when production expanded to keep pace with

demand. In the 1970's, however, world demand for oil began to outgrow what was available from non-OPEC sources. In 1973, OPEC stopped consulting with oil companies and decided to raise oil prices in keeping with the rate of inflation (the rise of all prices).

Armed conflict also contributed to rising oil prices. During the Arab-Israeli War of 1973, some Arab members of OPEC stopped or reduced oil exports to countries supporting Israel. As a result, oil prices in those countries, including the United States and other Western industrial nations, rose sharply. During the late 1970's, the Iranian revolution caused a shortage that helped OPEC increase oil prices again.

OPEC was less successful at achieving its goals in the 1980's, when the world oil supply again exceeded demand. In 1983, OPEC cut the price of its oil for the first time. During the middle and late 1980's, OPEC set production limits for its members several times. But many members ignored the limits, thereby holding prices down. Brief price increases resulted from Iraq's invasion of Kuwait in 1990, but since that time, oil prices have remained fairly stable.

Bob Williams

Orient is another name for the Asian countries and islands, or the East. See also Far East: Asia.

Oriental exclusion acts, a series of actions and acts approved by the United States government, restricted and prohibited Asians from entering the United States.

Chinese first came to the United States in large numbers after the discovery of gold in California in 1848. They were initially well received but met hostility as they moved into urban areas. Between 1864 and 1869, Chinese laborers were brought to the United States to help build the Central Pacific Railroad. In 1868, China and the United States signed the Burlingame Treaty to protect this immigration.

During the late 1970's, however, the immigration of Chinese coincided with an economic depression, and the Chinese were made the scapegoats. Americans accused them of unfair competition in business, of lowering wages, and of immoral and unsanitary habits. In some instances, they were victims of mob violence. Despite the treaty of 1868, Congress passed the Chinese Exclusion Act of 1882. This law and an extension of it that was passed in 1892 were intended to be only temporary, but Congress made exclusion permanent in 1902.

After the Chinese were barred, Japanese immigrants began coming to the United States in increasing numbers during the late 1800's. Many of them settled on the West Coast and became farmers. Their innovative farming methods, thrift, and low living standards made them a competitive force and aroused the anger of white farmers. California petitioned Congress to extend the Chinese exclusion law to the Japanese. In 1908, a "gentlemen's agreement" between the United States and Japan provided a temporary solution. Japan agreed to stop emigration of its workers to the United States, and the United States agreed to halt discriminatory immigration laws against the Japanese (see Gentlemen's agreement). The Immigration Act of 1924 prohibited the entry of all Asian laborers.

During World War II (1939-1945), Congress repealed the laws against the Chinese, permitting a limited number to enter the United States each year and be eligible for citizenship. The Immigration and Nationality Act of 1952 extended the same privileges to other immigrants, including the Japanese. The national quota system was abolished in 1965. Frank J. Coppa

See also Asian Americans (History of Asian immigration).

Origami, ər ə gə me, is the art of folding paper into decorative objects. The term is the Japanese word for folded paper. There are about 100 traditional origami figures. Most depict such natural forms as birds, flowers, and fish. An abstract, ceremonial form of origami,

called a noshi, is a pleated paper ornament attached to gifts. Most origami is folded from an uncut square of paper. The most common sizes of square are 15 centimeters and 25 centimeters (6 and 10 inches). The preferred paper is thin Japanese paper called washi. Foil-backed wrapping paper and heavy art paper are also used.

Origami, like paper, originated in China. But the art flourished in Japan. Since the 1940's, it has reached new levels of complexity and realism. Robert J. Lang

Orinoco River, ər uh NOH koh, is the longest river in Venezuela. It is 1,284 miles (2,066 kilometers) long. The Orinoco has two known sources, both in the Parima highlands in Venezuela, near the border of Brazil. The river flows northwest to Colombia and forms the boundary between Colombia and Venezuela. Then it swings east across Venezuela. About 110 miles (177 kilometers) before it reaches the seacoast, it divides into many channels. For location, see Venezuela (terrain map).

Small oceangoing vessels can sail 260 miles (418 kilometers) upstream from the mouth of the Orinoco. Ships can use the river for about 500 miles (800 kilometers) above the Maipures and Atures rapids. Ciudad Bolivar is the center of the Orinoco river trade. Steamships run
between Ciudad Bolivar and the island of Trinidad most of the year. Major branches of the Orinoco are the Apure, Caroni, and Meta rivers. Including its branches, the Orinoco has a navigable length of 4,300 miles (6,920 kilometers).

Gregory Knapp

Oriole, AWR ee ohl. In America, orioles form a subdivision of the blackbird family. In Europe, the name oriole is given to a family of orange and black birds related to the crows. Most of the American orioles live in or near the tropics. In Jamaica, they are known as banana birds.

The orchard oriole is a common American species of oriole. The male, left, has darker coloring than the female, right.

Three common species of orioles spend the summer in southern Canada and the United States—the Baltimore oriole, Bullock’s oriole, and the orchard oriole.

Orioles have beautifully colored feathers and loud, musical voices. They weave hanging nests and help farmers by eating insects. But in some areas, these birds may eat grapes. Some orioles are also called troupials.

Donald F. Bruning

Scientific classification. American orioles belong to the icterid family, Icteridae. The scientific name of the Baltimore oriole is Icterus galbula. Bullock’s oriole is I. bullockii, and the orchard oriole is I. spurius.

See also Baltimore oriole; Bird (pictures: Birds of forests and woodlands; Birds’ eggs).

Orion, aw RY uh or oh RY uh, was a handsome and energetic hunter in Greek mythology. He was a giant who could walk through the sea and on its surface.

Orion had a troubled love life. His wife was sent to Hades after she boasted that she was more beautiful than the goddess Hera (see Hades). Because Orion seduced her fiancé, Merope, her father, King Oenopion, blinded him. Helios, the sun god, restored Orion’s sight.

According to one myth, Artemis, the goddess of hunting, killed Orion because he tried to rape her. Another myth says that Artemis considered marrying Orion, but her jealous brother Apollo tricked her into hitting Orion with an arrow while he was swimming. In her sorrow at his death, Artemis placed Orion in the sky as a constellation. Another myth tells that Gaia, the earth, sent a scorpion to sting Orion to death.

Nancy Felson

Orion, aw RY uh or oh RY uh, the Hunter, is a brilliant constellation that includes two of the brightest stars in the sky. Orion is often pictured with his back turned toward us. In this view, the bright red star, Betelgeuse, marks his left shoulder. A blue-white star called Rigel marks his right foot. Two fainter stars, Bellatrix and Saiph, mark Orion’s right shoulder and left foot. Orion is easily identified by a row of three stars forming his belt. A sword, made of faint stars, dangles from the belt.

Two nebulae (clouds of gas and dust) are in Orion. The Great Nebula, in the middle of Orion’s sword, is visible as a misty spot under a dark sky. The Horsehead Nebula in Orion’s belt is difficult to see. David H. Levy

See also Betelgeuse; Nebula (picture); Star (picture: The constellation Orion).

Orizaba, aw uh ZAH buh or aw reh SAH vah, Pico de, is the highest mountain in Mexico and the third highest in North America. Only Mount McKinley and Mount Logan are higher. Pico de Orizaba rises 18,410 feet (5,611 meters) above sea level. Its Aztec name, Citlaltepetl, see ih tlah TAY peht uh, means “mountain of the star.” The mountain stands about 30 miles (48 kilometers) north of the city of Orizaba, Mexico. It is a volcano, part of Mexico’s Neo-Volcanic Chain, that last erupted in the late 1600s.

John J. Winberry

Orkney Islands are a group of islands that form part of Scotland. They are separated from the north coast of Scotland by the Pentland Firth, a channel about 7 miles (11 kilometers) wide (see Scotland [political map]). About 65 islands and some rocky isles make up the Orkney Islands, which have a total land area of about 377 square miles (976 square kilometers). The islands have about 19,000 people. Kirkwall and Stromness are the only towns. They lie on Mainland, the largest island. Nearly all the people are of Scandinavian or Scottish ancestry.

Rich soil and a mild climate help make agriculture the leading industry in the Orkney Islands. The chief products include cattle, cheese, eggs, and barley. Fishing is also an important economic activity. In addition, the islands have a major oil terminal that receives oil piped from wells in the North Sea.

Archaeological evidence indicates that people lived in the Orkney Islands about 5,000 years ago. Vikings from Norway ruled the islands from the A.D. 800s to the 1400s. Most of the islands’ place names are of Viking origin. Scotland (now part of the United Kingdom) acquired the Orkney Islands from Norway in 1469, when Scotland’s king, James III, married Princess Margaret of Norway and Denmark. The islands served as an important base for the British Navy during World War I (1914-1918) and World War II (1939-1945).

Orlando, awr LAN doh, Florida (pop. 185,951; met. area pop. 1,644,561), is a popular winter resort and tourist center. Orlando’s warm climate has helped make it one of the fastest-growing cities in the United States. Walt Disney World Resort opened about 15 miles (24 kilometers) southwest of the city in 1971. This famous entertainment center has contributed greatly to Orlando’s rapid growth. Many people, including large numbers of retired citizens, have settled in Orlando because of the mild climate. Orlando’s temperature averages 60 °F (16 °C) in January and 83 °F (28 °C) in July.

Orlando, the county seat of Orange County, lies in central Florida (see Florida [political map]). Its museums include the Orlando Science Center, which features the
Orlando, awr LAN doh, Vittorio Emanuele, veet TAW nyoh EH mah noo EE leh (1860-1952), served as prime minister of Italy from 1917 to 1919. He took office just after the Italian Army suffered a terrible defeat at Caporetto (now in Slovenia) in World War I. His efforts to restore civilian morale and army discipline helped keep Italy in the war, on the side of the Allies, until the Allied victory in 1918. After the war, he led the Italian delegation at the Paris Peace Conference in 1919. He temporarily left the conference in protest after the Allies refused to meet Italy's claims to former Austrian territories. His opponents in Parliament later forced him to resign as prime minister.

Orlando supported Benito Mussolini when Mussolini became prime minister of Italy in 1922. But Orlando denounced him in 1923 when Mussolini began openly to create a dictatorship. In 1946, when Italy's monarchy was abolished, Orlando helped establish the Italian republic.

Orlando was born on May 19, 1860, in Palermo.
Ornithomimus, awr nith uh MY muhs, was a dinosaur that resembled a modern ostrich. Its name, which means bird mimic, refers to the animal's birdlike appearance.

*Ornithomimus* measured about 10 to 13 feet (3 to 4 meters) in length and stood about 6 to 8 feet (1.8 to 2.4 meters) tall. It had a lightly built body with an elongated neck and tail; short arms; and long, strong hind legs. One of the fastest dinosaurs, *Ornithomimus* may have run as swiftly as an ostrich—30 to 40 miles (48 to 64 kilometers) per hour. It used its speed and keen eyesight to avoid predators. Its tail helped it balance during quick turns.

*Ornithomimus* had a toothless, beaklike mouth and probably ate eggs, insects, small animals, and fruit. The dinosaur used its long, claw-tipped fingers to uncover food on the ground or to dig for prey. It may also have stolen eggs from the nests of other dinosaurs.

*Ornithomimus* lived about 76 million to 65 million years ago, during the Late Cretaceous Period. Scientists have found its remains in western North America and central Asia.

David B. Weishampel

See also Dinosaur (pictures: Dinosaurs and birds; When dinosaurs lived).

**Ornithopod.** See Dinosaur (Kinds of dinosaurs).

**Ornithopter,** awr nuh THAHP tuh, is a machine designed to fly by flapping its wings like a bird. People have dreamed of such a vehicle since ancient times. Some small-scale models have flown. But all attempts to build ornithopters that carry people have failed because materials that are light enough and strong enough have not been developed.

Ornithopters are classified in two ways. The first type uses various forms of wings fastened to a person's body. The second type uses a cockpit to house the pilot. The wings are attached and operated from the cockpit. The English philosopher Roger Bacon suggested the idea of the ornithopter about 1250.

Roger E. Bilstein

**Ornithosis.** See Psittacosis.

**Oroville Dam,** OHR uh vil, is the highest dam in the United States. It rises 754 feet (230 meters) and extends 6,800 feet (2,073 meters) across the Feather River, near Oroville, California. The Oroville Dam is the chief dam of the State Water Project, which supplies irrigation water to central and southern California.

The dam is an earth-fill dam (see Dam (embankment dams)). About 80 million cubic yards (61 million cubic meters) of earth materials were used in its construction. It was completed in 1968. The materials came from waste piles at nearby gold-mining operations.

The Oroville Dam forms a reservoir called Lake Oroville, which contains about 3 ½ million acre-feet (4.3 billion cubic meters) of water. Water from Lake Oroville is used to irrigate farmland as far as 650 miles (1,050 kilometers) away in southern California. A hydroelectric power plant connected to the dam also uses the water. The dam also helps control floods.

Allen Soast

**Orozco,** oh ROHS koh, JOSE Clemente, hoh SAY klay MAYN tay (1883-1949), a Mexican painter, became known for murals that use themes from Mexico's history. His style emphasizes human figures who are portrayed with strong lines, dramatic angles, and brownish colors.

Orozco was born on Nov. 23, 1883, in Zapopan. He

spent his early career drawing political and satirical cartoons. In the early 1920's, Orozco and other Mexican artists began painting frescoes on walls in public buildings (see Fresco). Unlike the work of fellow muralists Diego Rivera and David Siqueiros, Orozco's frescoes seldom contain political messages. Instead, his paintings express his reaction to the struggles of common people everywhere.

In the 1930's, Orozco turned to a more abstract style. Examples of this style include the murals called *Epic of New World Culture* (1932-1934) in the Dartmouth College library in Hanover, New Hampshire, and murals in public buildings in Guadalajara and Mexico City. He died on Sept. 7, 1949.

Judith Berg Sobrè

**Orphanage.** See Children's home.

**Orpheus,** awr fee uhs or OHR fyoos, was a musician in Greek and Roman mythology. The music of his voice and lyre was so beautiful that animals, trees, and stones followed him, and rivers stopped flowing to listen. His mother was the muse Calliope, and his father was either the mortal Oeagus or the god Apollo.

Orpheus joined the Argonauts in their quest to capture the Golden Fleece. Later, he married Eurydice. After Eurydice died, he went to the underworld to bring her back. His music charmed Hades and Persephone, the rulers of the underworld, and they granted Eurydice permission to leave. But they warned Orpheus not to look back at her on the way up to the earth. He glanced back too soon and she disappeared. Orpheus angered some women of Thrace because he took no interest in them or in their worship of the god Dionysus, and they tore him to pieces.

Justin M. Glenn

See also Eurydice; Argonauts.

**Orr, Bobby** (1948-- ), was one of the greatest defense men in professional hockey history. He revolutionized the position with his graceful skating and extraordinary ability to carry the puck up the ice without weakening his team's defense. Orr's 139 points in the 1970-1971 season remains a record for National Hockey League (NHL) defensemen. Orr is the only defenseman to have

Larry Wigge

**Orrisroot,** *AWR ihh koo*, is the dried, sweet-smelling rhizome (underground stem) of certain irises. Orrisroot yields a waxy material containing a fragrant oil that is used to give perfumes a scent like that of violets. The oil is obtained by dissolving the waxy material in a fat or other organic substance. That substance is then removed leaving the oil.

Because of its high price, the oil has largely been replaced by synthetic substitutes. But small amounts are still used in some expensive perfumes. Orrisroot comes from irises cultivated in Italy, France, India, and Morocco.

James E. Simon

See also Iris.

**Ortega, awr TAY gah, Daniel** (1945- ), was head of Nicaragua's government from 1979 until 1990. In 1979, he was named the leader of a revolutionary government when his party, the Sandinista National Liberation Front, overthrew the government of Anastasio Somoza Debayle. Ortega was elected president of Nicaragua in 1984. His term as president ended in 1990, when he was defeated in a presidential election by Violeta Barrios de Chamorro, the leader of a coalition that opposed Sandinista rule. Ortega ran for president of Nicaragua again in 1996 and 2001, but he was defeated both times by candidates from the Liberal Constitutionalist Party.

Under Ortega, Nicaragua's government improved health care in rural areas, built many new schools, and reduced illiteracy. It also took control of many businesses, increased press censorship, and restricted the civil rights of its political opponents. Critics of Ortega, including the United States government, charged that he had set up a Communist dictatorship. In 1981, Nicaraguans who opposed Ortega's government—called contras—began a guerrilla war against it. In 1988, Ortega helped negotiate a cease-fire between his government and the contras.

Ortega's leadership of Nicaragua was greatly influenced by the country's relationship with the United States. The United States had been Nicaragua's chief trading partner until the Sandinista party came to power. The United States opposed Ortega's leadership. It sharply reduced trade with Nicaragua and provided funds to the contras. Ortega struggled to improve an economy crippled by the U.S. trade cuts, by the war against the contras, and by high government spending for health and education programs.

Ortega was born on Nov. 11, 1945, in the town of La Libertad. His full name is Daniel José Ortega Saavedra. During the 1960's, Ortega became a guerrilla leader of the Sandinista opposition to the Somoza government. He was imprisoned by the government from 1967 to 1974. After receiving military training in Cuba, he helped lead the overthrow of the Somoza government.

Neale J. Pearson

See also Nicaragua (Recent developments).

**Ortega y Gasset, awr TAY guh ee gah SEHT, José** (1883-1955), was a Spanish philosopher and essayist. He wrote *Meditations on Quixote* (1914), which anticipated themes that existentialist philosophers made popular more than 10 years later. Ortega emphasized the idea that we are "condemned to be free," and therefore all individuals must determine their own place in history. See Existentialism.

Ortega cherished aristocratic values. He believed that without spiritual leadership from the top, society would be drawn down to the level of its lowest members. For Ortega, this problem was especially serious because of the decline of self-confidence that he saw in Europe, and the rise of merely technical modes of thought and organization in the 1900's. He explored these ideas in his best-known book, *The Revolt of the Masses* (1930). In *The Dehumanization of Art* (1925), Ortega discussed the tendency of modern art to rid itself of human content.

Ortega was born on May 9, 1883, in Madrid. He was strongly influenced by the ideas of the German philosopher Immanuel Kant while he was studying in Germany. Ortega was professor of philosophy at Madrid University from 1910 to 1936. Because of the Spanish Civil War, he lived in exile from 1936 to 1945, when he returned to Spain. He died on Oct. 18, 1955.

Karl Ameriks

**Orthodontics,** *AWR thuh DAHN ihks,* is the branch of dentistry that prevents and corrects irregular positions of the teeth. In addition to causing poor personal appearance, irregularly positioned teeth are difficult to clean. Thus, they are more likely to decay and promote gum diseases (see Teeth Periodontal Diseases). Irregularly positioned teeth also can cause chewing and speech problems and can damage the jaw.

Irregularities in the position of teeth are called malocclusions. Malocclusions usually arise during childhood as the teeth grow. They most commonly occur when the teeth are too large for the available jaw space. Under such conditions, the teeth become crowded and turned out of position. In some cases, one of the jawbones is larger than the other, creating either an overbite or an underbite.

Malocclusions can sometimes be prevented by the early removal of certain deciduous teeth (baby teeth). This process, called *serial extraction or guidance eruption,* relieves crowding that occurs as new teeth break through the gums. If the teeth are already out of posi-
tion, orthodontists cement metal or plastic braces to the front of each tooth and connect the braces with wires. By gradually tightening the wires, they move the teeth into proper position. In some cases, a tooth is extracted so that other teeth can be moved into its place. Orthodontic treatment is sometimes combined with surgery on the jawbones to correct malocclusions.

Orthodontic treatment is typically begun when patients are 10 to 16 years old and lasts about two years. Many adults also undergo orthodontic treatment, but treatment time is generally longer. John P. Wortel

See also Dentistry (Orthodontics [picture]), Teeth (Malocclusion).

**Orthodox, Eastern.** See Eastern Orthodox Churches.

**Orthopedics,** *ahr-thuh PEE dihks,* is a branch of medicine that deals with disorders of the bones and muscles and their associated tissues. The word is also spelled *orthopaedics.* Doctors who practice orthopedics are called *orthopedists* or *orthopedic surgeons.* They treat a broad range of medical problems, including fractures, injuries to tendons and ligaments, and deformities of the limbs and spine.

Orthopedists provide care for patients who range from the newborn to the elderly. Some orthopedic disorders are present at birth. Others occur during childhood due to problems of growth or in later life as a result of aging. Still others result from injury or illness. People injured in automobile accidents and athletic or recreational activities account for a large number of the patients treated by orthopedists.

In treating orthopedic disorders, orthopedists prescribe drugs, surgery, or physical therapy. For example, an orthopedist may perform surgery to correct a fracture or deformity. After the surgery, the orthopedist may apply a cast or brace and prescribe physical therapy to aid healing. An orthopedist also may perform surgery to replace an injured or arthritic joint with an artificial joint made of plastic, metal, or other materials. Joints most commonly replaced include the hip, the knee, and joints in the hands and feet. William J. Kane

**Orwell, George,** was the pen name of Eric Arthur Blair (1903-1950), a British novelist and social critic. Orwell became famous with his novel *1984,* published in 1949. The book is a frightening portrait of a totalitarian society that punishes love, destroys privacy, and distorts truth. The novel includes the well-known statement "Big Brother Is Watching You." The grim tone of *1984* distinguishes it from Orwell's *Animal Farm* (1945), a fable satirizing Communism. In *Animal Farm,* Orwell wrote the familiar saying "All animals are equal, but some animals are more equal than others."

Orwell was a unique combination of middle-class intellectual and working-class reformer. A strong autobiographical element runs through most of Orwell's writing, giving both his novels and essays a sense of immediacy and conviction. Orwell's experiences living in poverty color *Down and Out in Paris and London* (1933), *A Clergyman's Daughter* (1935), and *The Road to Wigan Pier* (1937). The novels attack social injustice and range from the miseries and hypocrisies of the poor from middle-class backgrounds to the near-starvation of the slum-dweller. *Homage to Catalonia* (1938) is a nonfiction work based on Orwell's brief career as a soldier. In it, he describes his disillusionment with the Loyalists during the Spanish Civil War.

Orwell was born on June 25, 1903, in Bengal, India, the son of a British civil servant. He attended Eton from 1917 to 1921 and served with the Indian Imperial Police in Burma (now Myanmar) from 1922 to 1927. He lived in poverty in England and Europe until the mid-1930s.

Garrett Stewart

**Additional resources**

**Osage Indians, OH say,** once gathered food and hunted buffalo throughout a vast region of what are now Arkansas, Kansas, Missouri, and Oklahoma. The tribe also had permanent camps along the Osage River, which was named for them. The Osage lost most of their land to the United States government as a result of treaties made from 1808 to 1870. In 1872, the tribe moved to a reservation in Oklahoma and took up farming.

Oil was discovered on the Osage reservation in the late 1800s, and it produced income that made the tribe extremely wealthy. Many Osage then intermarried with whites and adopted white lifestyles. Today, however, the Osage are trying to preserve some aspects of their culture, including their language and religious ceremonies. Some Osage still live in Oklahoma, but many others live elsewhere.

Helen Marie Redbird-Smith

**Osage orange, OH say,** is a small- to medium-sized tree planted across the United States for hedges, ornamental purposes, and shade. It originally was found in Texas, Oklahoma, and Arkansas. The name refers to the Osage Indians of that region, and to the tree's greenish-yellow fruit, which looks like an orange but is inedible. The Osage orange is sometimes called bodark, bois d'arc, bowwood, or hedge apple.

The Osage orange has greenish-yellow fruit that resembles an orange. The tree has a short trunk and crooked branches and long, pointed leaves. Its yellow wood is hard and durable.
The tree has a short trunk and crooked branches. Its long, pointed leaves are a shiny, dark green. It has thorny twigs and a milky, bitter sap. Pioneers planted Osage orange trees as a "living fence" around their farms before barbed wire came into use. The yellow wood of the Osage orange is hard, strong, and durable. The Indians preferred it for their bows and war clubs. It makes good fence posts and was used for wagon wheels. A yellow dye can be made by boiling chips of the wood in water. Norman L. Christensen, Jr.

**Scientific classification.** The Osage orange tree belongs to the mulberry family, Moraceae. It is *Maclura pomifera.*

**Osaka,** *oh SAH kuh* (pop. 2,598,589), is the third largest city in Japan. Only Tokyo and Yokohama have more people. Osaka, an important industrial and commercial center, lies on Osaka Bay on the southern coast of Honshu Island (see Japan [political map]).

Osaka covers about 80 square miles (206 square kilometers). It is sometimes called the "Venice of Japan" because of its many canals and rivers. Since the 1960's, some of these waterways have been filled and highways built over them. Downtown Osaka lies on the delta of the Yodo River. Office buildings, stores, hotels, restaurants, and entertainment centers fill this section of the city. Many shopping centers have been built underground because of a shortage of land.

Osaka has many museums, theaters, and religious shrines. Osaka Castle, built in 1584, houses a museum with historical exhibits. Bunkaku Theater presents puppet shows, and Kabuki Theater offers stage performances. Osaka has 13 universities, including government-supported Osaka University. In 1970, Osaka was the site of Expo 70, the first world's fair to be held in Asia.

In the past, most Osakans lived in small wooden houses. Today, many Osaka residents live in large apartment buildings. The city's population increased by more than a million during the 1950's, and this rapid growth led to shortages of land and housing. Many Osakans have moved to the suburbs to escape the city's crowded conditions, high prices, and pollution.

Osaka is famous for its good food, especially seafood. Local specialties include eel; shrimp; turtle; and *kamaboko,* a fish stew cooked in a paper pot.

Osaka produces approximately 25 percent of all the products manufactured in Japan, including 40 percent of Japan's exports. Osaka exports clothing, electrical appliances, and fabrics. The city is also a financial and trade center.

Osaka has serious traffic problems in spite of efforts to improve public transportation. Buses, a subway system, and commuter trains serve the city. High-speed trains travel between Osaka and Tokyo, a distance of about 250 miles (400 kilometers). Osaka has two airports, Kansai International Airport and Osaka Airport. Kansai International is one of the busiest airports in Asia.

Osaka was settled in ancient times. It later became Japan's major port and commercial center. Toyotomi Hideyoshi, the ruler of Japan from 1585 to 1598, encouraged merchants to move to Osaka. The government opened Osaka's port to foreign trade in 1868.

Allied bombing raids destroyed much of Osaka during World War II (1939-1945). The people rebuilt their city following the war. Osaka's population growth created a need for more housing, sewers, highways, and subways. Many of these improvements were completed during the city's preparations for Expo 70.

Kenneth B. Pyle

**Osborn, Henry Fairfield** (1857-1935), was an American *paleontologist* (expert on prehistoric life). He was an authority on fossil vertebrate animals and evolution. His best-known work consisted of his studies of ancient reptiles and mammals. Osborn wrote about rhinoceroses; elephants and their relatives; and *titanotheres,* large mammals that once roamed the American West. Osborn's book *From the Greeks to Darwin* (1894) discussed evolution.

Osborn served as president of the American Museum of Natural History in New York City from 1908 to 1933. Under his administration, it became one of the world's largest museums. Osborn was born on Aug. 8, 1857, in Fairfield, Connecticut. Carolyn Merchant

**Osborne, John** (1929-1994), a British dramatist, became famous with his first important play, *Look Back in Anger* (1956). The drama deals with Jimmy Porter, an educated but poor young man. Porter lashes out at everyone around him in anger and frustration because the world no longer offers any ideals or causes he can believe in. The play was a vivid contrast to the sort of polite upper-middle-class stories and characters presented in most British plays of the time. Osborne continued the story of Jimmy Porter's life in *Dejavu* (1992).

Osborne's other early plays also criticized society. *The Entertainer* (1957) uses a run-down old comedian to symbolize the decline of the British Empire. *Luther* (1961) presents a modern interpretation of Reformation religious leader Martin Luther as a troubled rebel. *Inadmissible Evidence* (1964) portrays the breakdown of a successful lawyer as he realizes how empty his life is.

---

*Osaka,* Japan's third largest city, is an important commercial and cultural center. Numerous canals and rivers run through the city, which lies on the southern coast of Honshu Island.

*World Photo Service from Madeline Grimaldi*
As Osborne grew older, his plays became more conservative. He defended the way of life he had once criticized, and he attacked younger social critics. He also wrote an autobiography, *A Better Class of Person* (1981). John James Osborne was born on Dec. 12, 1929, in London. He died on Dec. 24, 1994.

Gerald M. Berkowitz

**Osborne, Thomas Mott** (1859-1926), was an American prison reformer. In 1913, as chairman of the New York State Commission for Prison Reform, he spent a week in prison, secretly, so he could understand and help prisoners. He served as warden of Sing Sing (New York) Prison from 1914 to 1916 and of Portsmouth (New Hampshire) Naval Prison from 1917 to 1920. Osborne organized the Mutual Welfare League to help prisoners rebuild their lives. He wrote *Within Prison Walls* (1914) and *Society and Prisons* (1916). Osborne was born on Sept. 23, 1859, in Auburn, New York, and died there on Oct. 20, 1926.

Louis Filler

**Oscar, AHS kuhn,** was a language used by one of the earliest known peoples of Italy. It was part of the Indo-European family and was distantly related to Latin.

**Oscar.** See Motion picture (Festivals and awards).

**Osceola, AHS ee OH luh** (1804-1838), led the Seminole Indians in Florida during the Second Seminole War (1835-1842). He fought attempts by the United States Army to move the tribe west of the Mississippi River to the Indian Territory.

Osceola was born in a Creek Indian village near the Tallapooza River in what is now eastern Alabama. The name Osceola, or Asi-Yaholo, comes from asi, a drink containing caffeine; and Yaholo, a cry shouted by the men who served asi during tribal ceremonies. After the Creek War (1813-1814), Osceola and many Creeks retreated to Florida and joined the Seminole.

During the 1820's, Osceola became known as a successful hunter and war leader. His warriors defeated United States troops in several battles early in the Second Seminole War. In 1837, Osceola met with U.S. troops under a flag of truce to discuss peace. But General Thomas Jesup ordered the troops to capture and imprison him. Osceola died soon afterward—on Jan. 30, 1838—in the Fort Moultrie prison near Charleston, South Carolina.

Many Americans were outraged by Jesup's trickery, and the Army's reputation fell sharply. Osceola won widespread respect. Several towns and counties were named for him.

**Oscillograph.** See Oscilloscope.

**Oscilloscope, uh SIHL uh skohp,** is an electronic instrument that displays changing electrical signals. The signals appear as wavy lines or in other patterns on a fluorescent screen.

Oscilloscopes are used in such fields as industry, medicine, and scientific research. Electronics engineers use the instruments to test computers, radios, and other electronic equipment. Physicians use them to study electrical impulses from the brain or heart. Light, mechanical motion, and sound can be studied with oscilloscopes. Devices called transducers change these forms of energy into electrical signals.

The screen of an oscilloscope is the front of a cathode-ray tube, a special type of vacuum tube. Inside the tube, a device called an electron gun projects a beam of electrons onto the fluorescent screen. Any sideways or up-and-down movement of this beam leaves a glowing line on the screen. A circuit called the time base causes the beam to move repeatedly from left to right. At the same time, the signal to be studied is fed into the oscilloscope and causes the beam to move up and down. This movement corresponds to oscillations (vibrations) in the signal. The beam moves up and down while moving from left to right. As a result, the beam traces a pattern on the screen that represents the oscillating signal.

A digital oscilloscope can "remember" the signal and so can recall and repeatedly display a brief event, such as the seismic wave of an earthquake. The oscilloscope measures the signal and stores it in a computerlike memory as a sequence of 1's and 0's. The measurements usually can be recalled at a faster or slower rate than they were recorded. For example, a seismic wave that lasted half a minute can be played back in as little as a fraction of a second.

An oscillograph is a type of oscilloscope that can record electrical signals. Certain types of oscillographs change electrical signals into mechanical movements that are recorded on paper or photographic film. For example, some oscillographs use a lightweight pen called a stylus to draw a wavy line on a moving paper chart.

**OSHA.** See Occupational Safety and Health Administration.

**Oshawa, AHSH uh wuh** (pop. 139,051; met. area pop. 296,298), is an important Canadian industrial city in Ontario. It is sometimes called Canada's Motor City. The city is the home of General Motors of Canada, the nation's largest manufacturer of motor vehicles. Oshawa lies on Lake Ontario in southeastern Ontario. For location, see Ontario (political map).
The Oshawa area was first settled in 1794, when Benjamin Wilson, a Vermont farmer, and his family moved there. In 1842, the community was named Oshawa, an American Indian word meaning crossing between the waters. The community was given this name because it lay between Lake Ontario and Lake Scugog.

In 1907, R. S. McLaughlin established the McLaughlin Motor Car Company in Oshawa. This firm produced McLaughlin-Buick automobiles. The Chevrolet Motor Car Company of Canada was established in Oshawa in 1915. The two firms united in 1918 to form General Motors of Canada. Oshawa received a city charter in 1924.

General Motors of Canada is Oshawa's chief employer. Other major employers include automobile parts manufacturers, the provincial headquarters of the Ontario Ministry of Revenue, the city's hospital, and regional school boards. Oshawa has a mayor-council form of government.

Osier, OH zuhr, is the name of certain shrubs and small trees in the willow family. They grow best along streams. These willows have tough, slender stems that can be used for making baskets and furniture. The common osier, also called basket willow, and the purple osier are willows that have been brought to the United States from other parts of the world. They are cultivated for their flexible stems. In the Northeast, they have escaped from cultivation and grow wild. One dogwood is called red-osier dogwood because its bark resembles that of some willows. See also Willow.

Scientific classification. Osiers belong to the willow family, Salicaceae. The common osier is Salix viminalis. The purple osier is S. purpurea. The red-osier dogwood is in the dogwood family, Cornaceae. It is Cornus stolonifera.

Richard C. Schlesinger

Osiris, oh SY rihs, was an Egyptian fertility god who became the chief god of the underworld. He is generally shown as a bearded human mummy with green or black flesh. He holds a shepherd's crook and a whip and wears a conical white crown with ostrich feathers.

As son of the earth god Geb, Osiris was regarded as a source of the earth's fertility. Egyptians sometimes compared him to the Nile River. As a popular Egyptian deity, Osiris was often identified with other deities. At Busiris in the delta region, he absorbed the characteristics of an earlier god-king. At the burial ground at Abydos, he replaced a god of the dead.

In Egyptian royal theology, the king was a living Horus, who was the son of Osiris. After the king died, he became Osiris. After Egyptian funeral practices became more democratic, every Egyptian expected to become an Osiris after death. Osiris was the central figure in Egypt's most popular myth. For an account of this myth, see Mythology (Egyptian mythology).

Orval Wintermute

Osler, OHS luhr, Sir William (1849-1919), was a Canadian physician and one of the greatest medical educators. His brilliant teaching and informal and genial personality greatly influenced many of his students. Through his students, Osler influenced medicine in English-speaking countries throughout the world.

One of Osler's most notable contributions to medicine was the organization of a clinic at the Johns Hopkins Hospital in Baltimore, Md. It became the model for modern medical education in the United States. Osler strongly favored using "the patient for a text," and he perfected the method of teaching that encourages students to become actively involved in patient care and learn the art of medicine at the bedside.

Osler discovered the presence in the bloodstream of what later were called disks, or blood platelets (see Blood [Platelets]). Among his many scientific papers are important studies of the heart and research on typhoid fever, pneumonia, malaria, infant mortality, and other medical and public health problems. He also helped found the Association of American Physicians in 1886 and the National Tuberculosis Association (now the American Lung Association) in 1904.

His writings. Osler published Principles and Practice of Medicine in 1892. For many years, it was a standard textbook in the United States. In 1897, a member of John D. Rockefeller's philanthropic staff read the book and was inspired by the potential of medical research, especially in microbiology. This incident led to the founding of the Rockefeller Institute for Medical Research in 1901. Osler's humanistic essays were collected in Aequanimitas (1904) and An Alabama Student (1908).

Sir William Osler

Osiris was one of the principal ancient Egyptian gods. He ruled the underworld and is often portrayed as a mummy seated on a throne wearing the crown of Upper Egypt.
Oslo is the capital and largest city of Norway. It also ranks as the country's leading seaport. Passenger ships, cargo vessels, and fishing boats dock at Oslo's busy harbor, above left. Many parks and gardens, such as the one shown above at the right, add to the scenic beauty of the city.
Osman I, AHZ muhn, AHS muhn, or ah MAHN(1258?-1326?), was the founder of the Ottoman Empire, which was named after him. Osman became known as a skillful military leader and a just ruler.

Osman, who is sometimes called Othman or Uthman, was probably born near Bursa, in northwestern Anatolia (now Turkey). His father was the leader of a group of nomadic Turks who were originally from Central Asia. According to some historical traditions, this group settled in Anatolia in the 1200's. At first, they served as soldiers for the Seljuks, who ruled much of the region. After he succeeded his father as leader in the 1280's, Osman established a small independent state in the Sakarya Valley in northwestern Anatolia.

Osman gradually expanded Ottoman territory by conquering small neighboring states or forming alliances with them. In 1301, he defeated an army of the nearby Byzantine Empire in the Battle of Baphaeon. About 1324, Osman turned over leadership of the Ottomans to his son Orhan.

Osmium, AHZ mee uhm, is a hard metallic element. It is one of the densest elements, with a density of 22.57 grams per cubic centimeter. Its atomic number is 76, and its atomic weight is 190.23. Its chemical symbol is Os. Smithson Tennant, a British chemist, discovered osmium in 1804. Osmium is rare and expensive and is found in the same ores as platinum. Osmium occurs in Alaska, Borneo, South Africa, and in meteorites.

Refined osmium is a fine, black powder or a hard, blue-gray mass. Osmium has a boiling point of 5012±100 °C and a melting point of 3033±30 °C. When heated in air, osmium forms osmium tetroxide (OsO₄), which vaporizes at about 100 °C. This compound can damage the eyes, skin, and lungs. It is used in certain scientific processes. Osmium alloys, which resist corrosion, are used to tip penpoints and are used in mechanical parts.

Osmosis, ahz MOH sihs, is the movement of liquid from one solution through a special membrane into a more concentrated solution. The process is essential for the survival of living things. For example, plants absorb most of their water by osmosis. In animals, osmosis helps regulate the flow of water and nutrients between body fluids and cells. Industries reverse osmosis for such purposes as water purification and food preservation.

A liquid solution consists of a dissolved substance called a solute, and a liquid called a solvent. During osmosis, some of the solvent from one solution moves through microscopic holes in a membrane into another solution. The membrane is semipermeable—that is, it allows solvent molecules to pass through its holes, but it blocks solute molecules. The solute molecules are larger than the holes in the membrane.

In osmosis, more solvent moves into the solution with the greater concentration of solute molecules. This occurs mostly because, in the weaker solution, there are fewer solute molecules blocking the movement of the solvent.

Solvent from the weaker solution continues to dilute the more concentrated solution until the concentrations are equal. At this point, the amount of solvent entering each solution equals the amount leaving each solution.

However, the flow of solvent will stop before the concentrations become equal if a certain pressure is exerted on the more concentrated solution. This pressure is called the osmotic pressure.

Experiment. Osmosis can be demonstrated by performing the following experiment. First, fasten a piece of cellophane over the bottom of a glass tube. Next, pour a solution of sugar and water into the tube. Then place the tube into a container of pure water so the levels of the water and the sugar solution are equal. After several hours, the liquid in the tube rises because of osmosis.

In this experiment, the cellophane is the semipermeable membrane. It allows water molecules to pass through but blocks sugar molecules. The sugar molecules are too large. In the tube, the sugar molecules interfere with the water molecules and prevent some wa-

An osmosis experiment

The process of osmosis can be demonstrated in the experiment shown above. Water enters the glass tube through the cellophane, which serves as a semipermeable membrane. As the water mixes with the sugar solution, the solution rises.

Molecules of water pass through the cellophane, as shown in the above diagram, but the larger sugar molecules do not. The level of the sugar solution rises because more water molecules move into the solution than out of it.
ter from moving through the membrane. As a result, more water moves into the tube than out of it.

As water moves into the tube, the sugar solution rises, thereby increasing the pressure in the tube. The solution continues to rise until the pressure that it exerts equals that of the pure water.

Reverse osmosis. Chemists use a process called reverse osmosis to purify water and perform other functions. In normal osmosis, water flows from fresh water into seawater when they are separated by an appropriate semipermeable membrane. But, by applying pressure to the seawater, chemists can reverse the movement of the water and produce fresh water from seawater. Some shipwreck victims have used survival kits that convert seawater into drinking water by osmosis [see Water (diagram: Reverse osmosis)].

Osprey, *AH*s pree or *AH*s spray; also called fish hawk, is a fish-eating bird. Ospreys feed by making spectacular plunges into water from heights of 50 to 100 feet (15 to 30 meters). They hit the water feet first with a great splash and seize a fish with their long, slender claws. These birds live throughout the world along rivers, lakes, seacoasts, and bays. Ospreys in northern regions migrate to warm areas for the winter.

The osprey is about 2 feet (60 centimeters) long, with a wingspread of nearly 6 feet (1.8 meters). It is dark brown above and has some white on its head. It is white below with a few streaks of dark brown.

Ospreys nest in trees, jagged rocks, or low bushes, or on the ground. Ospreys build the largest nests of any North American birds. Some measure up to 6 feet (1.8 meters) high. Nest-building materials include seaweed, sticks, bones, or driftwood. In North America, during April or May, ospreys usually lay three eggs. Incubation of the eggs lasts about 37 days.

Insecticides, such as DDT, and human disturbance of the bird's habitat reduced the number of ospreys in several locations. However, conservation measures on the United States mainland helped to increase the osprey population.

Scientific classification. The osprey belongs to the family Accipitridae. Its scientific name is *Pandion haliaetus*.

Ossining Correctional Facility. See Sing Sing.

Ostend, ah STEHND (pop. 69,067), is a Belgian city on the North Sea, about 77 miles (124 kilometers) northwest of Brussels [see Belgium (political map)]. Ostend lies in the Dutch-speaking region of Belgium. Its name in Dutch is *Oostende*. It is an important Belgian port. Ostend conducts an export-import business with many countries. The city serves as the harbor for cross-channel boats from Dover, England. Ostend fishing crews catch cod and herring. Oysters are cultivated offshore. Ostend is a fashionable summer resort. Visitors enjoy its sea walk and listen to concerts in a building called the Kursaal.

Dutch, Spanish, and French troops have fought many battles for Ostend because of its value as a port. In 1865, its fortifications were destroyed by the Belgian government, and Ostend became important for shipping. Ostend was damaged in World War I (1914-1918) and again in World War II (1939-1945).

Ostend Manifesto, ah STEHND, was a controversial document drafted in 1854 as part of a plan by the United States to acquire the colony of Cuba from Spain. It stated that the United States might be justified in seizing Cuba for reasons of national security if Spain refused to sell the island.

During the mid-1800's, several United States leaders wanted to annex Cuba as a new slave state. In 1854, William L. Marcy, secretary of state under President Franklin Pierce, asked three United States diplomats to make recommendations for the acquisition of Cuba. They were Minister to Spain Pierre Soule, Minister to France John Y. Mason, and Minister to Britain James Buchanan. They met at Ostend, Belgium, in October 1854.

Newspapers obtained copies of the ministers' dispatch. They called it the Ostend Manifesto and published it in 1855. The implied threat to seize Cuba added to the uproar started in 1854 by the Kansas-Nebraska Act, which made slavery possible in two new United States territories. Pierce took no further action to gain Cuba. But the Ostend Manifesto added to the growing conflict over slavery between the North and the South.

Osteomyelitis, *AH*s teh oh nuh uh LY ihhs, is an inflammation of bone and bone marrow, the jellylike material in the core of bones. Osteomyelitis is caused by infection, usually from a bacterium called *Staphylococcus aureus*. Infection of bone marrow may occur if a person has a compound fracture. In such a fracture, bone marrow may be exposed to air containing bacteria. In other cases, the blood carries bacteria from a boil, from infected tonsils, or from infection somewhere else in the body to the bone marrow. Symptoms of acute osteomyelitis include fever, chills, pain over the infected bone, and nausea. Doctors usually treat the infection with antibiotics.

Madison B. Cole, Jr.

Osteopathic medicine, *AH*s teh uh PATH ihk, is a system of medical care based on the belief that all body systems are interrelated. Disease in one part of the body
Osteopathic medicine involves all aspects of medicine and includes various medical specialties. Osteopathic physicians use all the medical, surgical, immunological, pharmacological, psychological, and hygienic procedures of modern medicine.

The musculoskeletal system makes up 60 percent of the body's weight. Because this system is so extensive, osteopathic medicine maintains that it has especially important interrelationships with other body systems. The musculoskeletal system may be affected by many internal illnesses and, in turn, may speed or worsen the process of disease in other body systems, including the circulatory system and the nervous system. Osteopathic physicians are trained to use osteopathic manipulation of the musculoskeletal system as a diagnostic and treatment tool, when it is appropriate. Such osteopathic manipulative treatment (OMT) is a distinctly osteopathic approach to the problems of health and disease.

History. The founder of osteopathic medicine was Andrew Taylor Still, an American medical practitioner. Still announced the basic principles of the osteopathic system in 1874. In 1892, he organized the first osteopathic college, which was established at Kirksville, Missouri.

The first law regulating osteopathic medicine was passed in Vermont in 1896. There are now such laws in all the states, and in some of the provinces of Canada. In every state, graduates of osteopathic medical schools are eligible to be licensed as physicians and surgeons.

Careers in osteopathic medicine. To become an osteopathic physician, a person must complete four years of preprofessional training in an accredited college or university and four years of professional education in an approved osteopathic medical college. The graduate receives a Doctor of Osteopathy (D.O.) degree. There are 15 approved colleges of osteopathic medicine in the United States. After graduating, osteopathic physicians gain additional training by spending a year as an intern in an approved osteopathic hospital. The United States has about 180 osteopathic hospitals, about 130 of which offer intern training programs.

Osteopathic physicians may become certified specialists in any of a number of medical fields. Certification programs require two to five years of additional training after internship. More than 28,000 osteopathic physicians practice in the United States. Most of them are members of the American Osteopathic Association, which has its headquarters in Chicago.

Additional resources

Osteoporosis, "oh stee oh por uh sih," is a condition in which bones become abnormally fragile. It is a major cause of pain and disability in older adults. People with osteoporosis have an increased risk of breaking bones throughout their bodies, especially in their wrists, spine, and hips. Breaks may result from minor falls or injuries that would not harm normal bones. Severely affected bones—especially in the spine—may collapse just from the pressure of holding up the body's own weight.

Causes. Osteoporosis occurs as a result of bone loss through a lifelong process called remodeling or bone turnover. Remodeling is the chief means by which bones repair themselves. In remodeling, certain bone cells remove worn tissue and other cells form new bone. But the amount of new bone falls short of the amount lost by a tiny fraction. As a result, bone density gradually declines after reaching a peak in early adulthood, when a person finishes growing. In osteoporosis, bone density drops below the level needed to keep bones strong and prevent them from breaking.

Many factors can trigger osteoporosis. Some people form less bone than average, due to heredity or inadequate diet. These people may develop osteoporosis as normal bone loss occurs with age. Other people begin with normal bones but have greater than usual bone loss as they grow older. Factors that can cause excessive bone loss include injury, prolonged lack of exercise, and certain hormonal, inflammatory, and digestive disorders.

Healthy bone is strong because the tissue making up its microscopic honeycomblike structures is smooth and dense.

Bone affected by osteoporosis is weakened by loss of bone tissue, leaving pits in its microscopic honeycomblike structure.
Osteosclerosis

One common form of osteoporosis affects women who have passed menopause, the time when menstruation stops. Around menopause, production of the hormone estrogen decreases greatly. Lack of estrogen increases the rate of remodeling, which in turn speeds up the gradual bone loss that accompanies the process.

Prevention and treatment. People need to consume enough calcium and vitamin D to form and maintain healthy bones. Doctors recommend that everyone—especially women—eat three or more calcium-rich servings of dairy products each day. People who cannot eat dairy products can take calcium supplements. Regular exercise also helps keep bones strong.

Certain tests use X rays or sound waves to measure bone density. For people with low bone density, several treatments in addition to diet and exercise help limit further bone loss. Some women who have passed menopause can take medication called hormone replacement therapy to supply the body with estrogen or estrogen-like compounds. Scientists have also developed nonhormone drugs that help preserve bone in men and in women who cannot take hormones. Robert Marcus

See also Bone; Hormone replacement therapy; Menopause; Nutrition (Minerals).

Osteosclerosis, aw tee oh skih ROH sihs, means hardening, thickening, and increased density of bone. It may involve part of a bone, a whole bone, or the whole skeleton. The most common form, called marble bones or osteopetrosis, is a rare inherited disease that occurs in children. In this disease, the bones become excessively dense and thick. This increased thickness fills in the space containing the bone marrow, the tissue that makes red blood cells. As a result, the child develops severe anemia. Bones affected by osteosclerosis become brittle and fracture more easily than do normal bones. Osteosclerosis may develop in part of a bone as a result of an infection or tumor. Madison B. Cole, Jr.

Ostracoderm. See Fish (The first fish).

Ostrava, AW strah vah (op. 331,448), is one of the largest cities in the Czech Republic. It lies in the northeastern part of the country (see Czech Republic [map]).

Ostrava is the center of the country’s largest industrial area. The city is known for its great iron and steel works and its manufacture of metal products. The region also has chemical plants, coal mines, and oil refineries. Other products of Ostrava include food products, furniture, house-building materials, and wearing apparel. Vojtech Mastny

Ostrich is the largest living bird. It may stand nearly 8 feet (2.4 meters) tall and weigh as much as 345 pounds (156 kilograms). Ostriches live on the plains and deserts of Africa. The extinct moas of New Zealand, which were 10 feet (3 meters) tall, were the only birds taller than ostriches. The extinct elephant birds of Madagascar, which weighed about 1,000 pounds (450 kilograms), were the only heavier birds. See Elephant bird; Moa.

The ostrich is the only bird that has two toes on each foot. The rhea, which is also called the South American ostrich, is three-toed and is not a true ostrich. See Rhea.

The male ostrich has black feathers on its bulky body, with large white feathers, called plumes, on its wings and tail. All the feathers on a female ostrich are dull brown. The ostrich’s long, thin legs, upper neck, and small head have almost no feathers. The bare skin ranges in color from pink to blue. Thick black eyelashes surround its eyes, which are almost 2 inches (5 centimeters) in diameter.

The male ostrich has an unusual voice. It gives a deep roar like that of a lion, but with a strange hissing sound. The ostrich cannot fly, but it is known for its speed on the ground. Its long legs can take 15-foot (4.6-meter) steps at speeds up to 40 miles (64 kilometers) per hour.

The ostrich’s speed and sharp eyesight help it escape from its enemies, mainly lions, cheetahs, and people. When the ostrich is exhausted and cannot run any farther, or if it must defend its nest, it kicks with its powerful legs. Its long toes, the largest of which is 7 inches (18 centimeters) long, have thick nails that serve as weapons when the bird is cornered. The belief that the ostrich hides its head in the sand when frightened is not true, but stems from the bird’s habit of rearranging the eggs in its nest with its bill. From a distance, this appears to cause the ostrich’s head to disappear into the sand.

How the ostrich lives. The ostrich usually eats plants, but it will eat lizards and turtles if it can find them. It also eats much sand and gravel to help grind food for digestion. Ostriches drink water when they find it. But they can live for long periods without drinking if the plants they eat are green and moist.

Ostriches are polygamous—that is, the male has more than one mate. Each cock (male) digs a shallow nest in sand, and from three to five hens (females) lay their eggs in the nest. Each hen lays as many as 10 eggs. Each egg is almost round, nearly 6 inches (15 centimeters) in diameter, and weighs about 3 pounds (1.4 kilograms). The
A female ostrich stands guard over a nest of eggs. Three to five females lay their eggs in the same nest.

eggs are a dull yellow and have large pores and a thick shell. The male sits on the eggs at night. But during the day the dominant hen—which is usually the oldest hen—helps keep them warm. The eggs hatch in about six weeks. When an ostrich is a month old, it can run as fast as an adult. Ostriches can live to about 70 years of age. Few other birds live so long.

Ostrich farming. Hundreds of years ago, great flocks of ostriches roamed over Africa and western Asia. Arabs in western Asia hunted ostriches for sport, and Africans took their eggs for food or killed the birds for their feathers.

In the late 1800s and early 1900s, ostrich plumes became popular as decorations on hats and clothing. Large numbers of ostriches were killed for their plumes, and the birds disappeared from Asia and from much of Africa. Ostrich plumes were in great demand and were so expensive that it became highly profitable to raise ostriches in captivity. Plumes could be taken twice a year from live birds kept on ostrich farms. Ostrich farms were established in Africa, Australia, southern Europe, and the United States. But between 1914 and 1918, fashions changed and the market for ostrich plumes dropped sharply.

Today most ostrich farms are in South Africa and Israel, but a few can be found in the United States. Ostriches are now raised primarily for their skin, which provides fine quality leather to make gloves, shoes, and bags. Ostrich eggs and meat are considered great delicacies in some parts of the world. In addition, ostriches are popular zoo animals because of their unusual appearance and usually mild disposition.

Scientific classification. The ostrich is in the ostrich family, Struthionidae. Its scientific name is Struthio camelus.

John W. Fitzpatrick

Ostrovy, Alexander. See Russian literature (Early realism).

Ostwald, OHST vahl, Wilhelm, VHL behlm (1853-1932), a German chemist, writer, and teacher, won the 1909 Nobel Prize for chemistry. He received the award mainly for his studies in surface phenomena and speeds of chemical reactions. Ostwald wrote one of the early books on electrochemistry. His research on the oxidation of ammonia helped Germany make explosives during World War I (1914-1918). Ostwald was born in Riga, Latvia. Arthur L. Miller

Ostwald process. See Nitric acid.

Oswald, Lee Harvey (1939-1963), was accused of assassinating President John F. Kennedy on Nov. 22, 1963, in Dallas, Tex. Two days later, while millions of television viewers looked on, Oswald was killed. He was shot to death by Dallas night-club owner Jack Ruby, while being transferred from the city jail to the county jail in Dallas. Ruby pushed through a ring of police officers to shoot Oswald down.

No one saw Oswald shoot the President. The high-powered Italian rifle said to have killed the President was traced to Oswald through a Chicago mail-order firm. Oswald worked in the Texas School Book Depository, the building from which the fatal shots were fired. A worker recalled seeing Oswald carry a long narrow package into the building the morning of the assassination. Police captured Oswald, who was armed with a revolver, in a Dallas motion picture theater about 90 minutes after the assassination.

Oswald was also charged with killing police officer J. D. Tippit. Tippit was shot to death in Dallas shortly after the President was killed. But Oswald denied killing either Tippit or the President. A presidential commission headed by Chief Justice Earl Warren investigated the case. After a 10-month investigation, the commission reported in September 1964, that Oswald, acting alone, had killed Kennedy and Tippit. However, a congressional committee later reexamined the evidence and

A baby ostrich has spotted down that blends with the ground and helps protect the bird from its enemies.
concluded that Kennedy "was probably assassinated as a result of a conspiracy."

A Dallas jury convicted Ruby of Oswald's murder in 1964. The conviction was reversed in 1966 on the grounds that the trial judge had allowed illegal testimony. A new trial was ordered, but Ruby died in 1967 before the new trial started.

Oswald was born in New Orleans. Investigators said his school and military records showed emotional difficulty. Oswald dropped out of high school at 17 and joined the U.S. Marine Corps. He was discharged in September 1959 and went to the Soviet Union a month later. He tried to become a Soviet citizen but was turned down. He returned to the United States in 1962 with his Soviet-born wife, Marina.

A few people believed that Oswald never returned to the United States. They maintained that a Soviet agent assumed Oswald's identity and killed Kennedy. But in 1981, Oswald's grave was opened, and medical experts identified the body as Oswald's.

Oswego, New York (pop. 17,954), is the easternmost port on the Great Lakes. It lies at the point where the Oswego River empties into Lake Ontario (see New York [political map]). The name Oswego comes from an Iroquois Indian word meaning pouring out place. The city's factories produce rolled aluminum, fabricated steel products, paper products, pumps, and wire. Oswego's Nine Mile Point nuclear power plant generates electricity for several northeastern states. The city is also home to the State University of New York College at Oswego.

Oswego stands on the site of a British and Dutch fur-trading post founded about 1722. The British controlled Oswego until 1796 and again during the War of 1812. Oswego became a village in 1828 and a city in 1848.

With the opening of the Saint Lawrence Seaway in 1959, Oswego became a major world port. It has a mayor-council form of government.

John Kenneth White

Otis, Eliza Graves (1811-1861), was an American inventor who built the first elevator with an automatic safety device. The device prevented the elevator from falling if the rope that held the elevator broke. Otis demonstrated his elevator in 1834 in New York City by having the rope cut after he had ascended in the elevator. But his invention did not come into wide use until the rise of the skyscraper in the late 1800's.

Otis was born in Halifax, Vermont. From 1830 to 1851, he held various jobs that developed his mechanical ability. By 1851, he was master mechanic at a firm that made bedsteads. The firm sent Otis to Yonkers, New York, in 1852 to supervise the installation of machinery in a new factory. That year, Otis invented the safety elevator while building an elevator for the factory.

Michael M. Sokal

See also Elevator (picture).

Otis, James (1725-1783), was an American patriot and agitator against the United Kingdom. In 1756, he became the British king's advocate general (representative) on the vice-admiralty court at Boston. This court dealt with cases involving the sea and shipping. In 1760, Otis resigned his post in protest over the issuing of new writs of assistance, general search warrants that did not name the place to be searched. British authorities wanted to use the writs to catch colonists who smuggled goods into the colonies to avoid paying British trade taxes. Otis argued that the writs violated the British constitution and the laws of nature.

In 1761, Otis became one of Boston's four representatives in the Massachusetts legislature. There he proposed a meeting of representatives of all the colonies. His suggestion eventually led to the Stamp Act Congress of 1765, in which delegates from nine colonies gathered to consider joint action against the British.

In 1769, Otis was attacked by British revenue officers who resented his criticism of them. A head wound he received during the attack eventually caused him to lose his mind. He was killed by lightning.

Otis was born in West Barnstable, Massachusetts. His sister Mercy Otis Warren was a writer who also became active in the American independence movement.

Robert A. Becker

Otoscope is an instrument that doctors use to examine the eardrum. The otoscope consists of a magnifying lens and a light that is powered by a battery. The light illuminates the eardrum and the lens magnifies it about six times. The otoscope makes it possible for the doctor to see changes in the eardrum resulting from infections and diseases.

Frank E. Musiek

James Otis was one of the most forceful leaders in the American colonies' struggle for independence from the British.
Ottawa, the capital of Canada, lies along the Ottawa River. The Rideau Canal joins the river near the slopes of Parliament Hill. The green-roofed Parliament buildings stand atop the hill.

**Ottawa, *AHT uh wah*:** Ontario, is the capital of Canada. It lies on gently rolling hills along the south bank of the Ottawa River, about 110 miles (175 kilometers) west of Montreal. Attractive parks, stately government buildings, and scenic drives add beauty to the city. Ottawa faces the city of Gatineau, Quebec, across the Ottawa River.

Parliament Hill, the site of Canada’s Parliament buildings, borders the Ottawa River and offers a dramatic view of the heart of Ottawa. It has wooded slopes and beautiful lawns. The Peace Tower, a memorial to Canada’s war dead, dominates the hill. The memorial rises 292 feet (89 meters).

In 1826, British troops founded the first settlement in the area that is now Ottawa. The soldiers had come to build the Rideau Canal, which links the Ottawa River and Lake Ontario. The town that sprang up around the construction site became known as Bytown. In 1855, the townspeople changed its name to *Ottawa*, adapted from the Indian word *Outaouak*. The Outaouak were Algonquin Indians that settled and traded furs in the area.

Ottawa was a small lumbering town when Queen Victoria chose it in 1857 to be the capital of the United Province of Canada. The Dominion of Canada was established in 1867, with Ottawa as its capital. The city’s layout has been greatly changed through the years in keeping with Ottawa’s standing as a national capital.

**Metropolitan Ottawa**

The city of Ottawa covers 1,073 square miles (2,779 square kilometers), more than 90 percent of which is rural area. The Rideau River flows through Ottawa from the south. It plunges 37 feet (11 meters) over a cliff into the Ottawa River at the northeastern end of the city, forming the Rideau Falls. The Rideau Canal cuts through the city on its way from the Ottawa River to Lake Ontario (see Rideau Canal).

Parliament Hill borders the Ottawa River just west.

**Facts in brief**

- **Population:** 774,072. **Metropolitan area population**—1,063,664.
- **Area:** 1,073 mi² (2,779 km²). **Metropolitan area**—2,053 mi² (5,318 km²).
- **Climate:** Average temperature—January, 20 °F (−6.4 °C); July, 69 °F (21 °C). **Average annual precipitation** (rainfall, melted snow, and other forms of moisture)—34.24 in (86.97 cm). For the monthly weather in Ottawa, see Ontario (Climate).
- **Government:** Mayor-council. **Terms**—3 years for the mayor and 21 council members.
- **Founded:** 1826. Incorporated as a city in 1855.
of the canal. The graceful spires and green roofs of the three Parliament buildings rise above a bluff near the river. The Peace Tower, topped by a lighted clock, stands out above the buildings. The Peace Tower houses a carillon of 53 bells that weigh a total of 60 tons (54 metric tons).

The areas immediately to the west and east of the Rideau Canal are the oldest parts of Ottawa. The city's chief shopping districts center around the Sparks Street Mall to the west of the canal and Byward Market and Rideau Street to the east.

Ottawa includes the urban and rural areas that, until Jan. 1, 2001, had been part of the region of Ottawa-Carleton and the municipalities of Cumberland, Gloucester, Goulbourn, Kanata, Nepean, Osgoode, Rideau, Rockcliffe Park, Vanier, and West Carleton. The Ottawa metropolitan region also includes the Outaouais, an area in western Quebec directly across the Ottawa River from Ottawa. The main city in the Outaouais is Gatineau. It consists of five former Quebec municipalities—Aylmer, Buckingham, Gatineau, Hull, and Masson-Angers—that merged on Jan. 1, 2002.

A visitor's guide

Millions of tourists visit the Ottawa-Gatineau area yearly. They come to see Parliament in action and to view such attractions as the Peace Tower and the eight locks of the Rideau Canal. Ottawa's annual festivals and fairs, its many museums, and the Casino du Lac-Leamy also attract many visitors to the area.

Following are brief descriptions of some interesting places and cultural attractions in Ottawa.

The Parliament buildings rank as Ottawa's most popular tourist attraction. These three buildings—the Centre Block, the East Block, and the West Block—form three sides of a 35-acre (14-hectare) square.

The Prince of Wales, who later became King Edward VII of the United Kingdom, laid the first stone of the Centre Block in 1860. The three buildings were completed in 1865. Fire destroyed most of the Centre Block in 1916, and only the eight-sided Library of Parliament remained. After being rebuilt along the lines of the earlier structure, the Centre Block reopened in 1920.

The Centre Block includes the House of Commons, the Senate chamber, the Peace Tower, and offices of members of Parliament. Canada's prime minister has an office in the East Block. The West Block contains offices for some members of Parliament and other government officials. During July and August, the Governor General's Foot Guards and the Canadian Grenadier Guards perform a daily changing-the-guard ceremony in front of the Peace Tower.

Other government buildings include the Royal Canadian Mint, where visitors may watch coins being made. The National Library and Public Archives building exhibits historical documents. The Canadian Supreme Court building also attracts many visitors.

Rideau Hall, also called Government House, is the official residence of the Canadian governor general. It stands near the mouth of the Rideau River. Thomas McKay, a lumberman, built it in 1838. The Canadian government bought this gray limestone building in 1868 for Viscount Monck, the first governor general. The home of the prime minister is nearby.

The National War Memorial, at Confederation Square, honors the Canadians who died in action during World Wars I and II. It consists of bronze figures of servicemen and servicewomen marching through a granite arch.

The National Arts Centre, in the heart of Ottawa, opened in 1969. This structure houses a 2,300-seat opera and concert hall, a theater with 800 seats, and a smaller theater with 300 seats. The National Arts Centre Orchestra performs in the concert hall.

Museums. The National Gallery of Canada has Canadian and European paintings and sculpture. In addition, it regularly hosts special exhibitions of international artists. The Canadian Museum of Nature features minerals, animals, and fossils. The Canada Science and Technology Museum has Canadian aircraft. Laurier House, the former residence of Canadian Prime Ministers Sir Wilfrid Laurier and W. L. Mackenzie King, has been pre-
served as a historical museum. The Canadian War Museum houses the most extensive military collection in Canada. At the Canadian Museum of Civilization, exhibits trace Canada’s development from the Vikings to the present and illustrate the cultures of Inuit (formerly called Eskimos) and Indians. This museum is located in nearby Gatineau, Quebec.

**Parks and recreation.** The Ottawa region has more than 7,980 acres (3,230 hectares) of parks and playgrounds. The Ottawa Senators of the National Hockey League play in the Corel Centre in the community of Kanata. The Central Experimental Farm and the Dow’s Lake area include many attractive gardens.

**Annual events** in Ottawa include the 10-day Canadian Tulip Festival in May. More than 3 million tulip bulbs bloom in parks, along roadways, and on the grounds of public buildings. Former Queen Juliana of the Netherlands sent the bulbs as a gift to Ottawa. During World War II (1939-1945), Juliana, then a princess, lived in Ottawa while German troops occupied her country. After returning home, she sent Ottawa 100,000 tulip bulbs in gratitude for the city’s hospitality and for Canada’s role in freeing her country. Juliana sent Ottawa 15,000 tulip bulbs for the festival annually until her abdication in 1980. Since 1980, the government of the Netherlands has continued to send the tulip bulbs for the annual festival. Ottawa holds a winter festival called Winterlude over three weekends in February. The festival features snow sculptures and ice carvings and such sports as broomball, ice skating, and dog-sled racing. The Franco-Ontarian Festival, held in the city every June, celebrates the French-Canadian culture of Ontario. Its features include art exhibits and folk dancing. Every August, the Central Canada Exhibition at Lansdowne Park offers agricultural, industrial, and scientific exhibits. The city’s jazz, blues, and folk festivals, which are held in the summer, are also popular.

**People**

Most of the people in the Ottawa area were born in

---

**City of Ottawa**

Ottawa, the capital of Canada, lies on the Ottawa River in southeastern Ontario. It is an important high-technology center. The map at the right shows major points of interest in and near Ottawa.

---

**World Book maps**
Canada. Most of the rest immigrated from Asia, Western Europe, or the United States.

A majority of the people in the Ottawa area have some British or French ancestry. About three-fifths of the residents of Ottawa speak English as their first language. French is the first language of approximately one-sixth of the population.

**Economy**

**Industry and commerce.** The Canadian government ranks as Ottawa's largest employer. More than 72,000 of the Ottawa area's residents work for the Canadian government.

The Ottawa area is also a high-technology center and is sometimes called Canada's Advanced Technology Capital. More than 800 high-technology companies employ more than 48,000 people in the Ottawa area. These companies specialize in advanced research and development in a number of fields, including computer software, environmental technology, space science, and telecommunications.

More than 18,000 residents of the Ottawa area work in health care and related industries. Tourism is also an important part of the area's economy.

**Transportation.** Many major airlines use the Ottawa MacDonald-Cartier International Airport, and passenger and freight trains also serve the city. Ottawa has a fine highway system, including scenic drives that run parallel to the Rideau Canal on both sides. The highway system extends across the Ottawa River into the Gatineau Hills. Two city-owned bus companies provide local service. Four vehicle bridges connect Ottawa with Gatineau.

The Ottawa River links the city with Montreal, and the Rideau Canal connects it with Kingston, Ontario. But water transportation plays only a small part in Ottawa's economy.

**Communication.** Ottawa has three daily newspapers. The *Ottawa Citizen* and the *Ottawa Sun* are printed in English, and *Le Droit* is printed in French. Four local television stations broadcast in Ottawa, three in English and one in French. Of the 16 radio stations in Ottawa, 14 broadcast in English and 2 in French.

**Education**

**Schools.** Ottawa has about 280 elementary and secondary schools, almost evenly divided between public and Roman Catholic institutions. The city is the home of Carleton University and the University of Ottawa. About 18,000 students attend Carleton, and more than 25,000 attend the University of Ottawa. The University of Ottawa, founded in 1848 as the College of Bytown, offers most of its courses in both English and French. St. Paul University and the Dominican College of Philosophy and Theology are also in Ottawa.

**Libraries.** The Ottawa Public Library has several branches throughout the city. In addition to books, the library carries many films and other audio and visual aids. Ottawa is also home to the Library of Parliament and the National Library of Canada.

**Government**

Ottawa has a mayor-council form of government. The voters elect a mayor and 21 council members to three-year terms. Taxes on property, sales, and businesses provide most of the government's revenue. Ottawa also receives federal and provincial grants.

**History**

**Early days.** Centuries ago, Algonquin and Iroquoian Indians traveled down the Ottawa River on hunting and trading trips. They went ashore at what is now Ottawa and carried their canoes around the Chaudière Falls. In 1613, the French explorer Samuel de Champlain passed through the area. French fur traders used the Ottawa River as a route to the west.

In 1800, Philemon Wright, a farmer from Massachusetts, took over a large tract of land on the north side of the Ottawa River. He built a sawmill and began a lumber business that grew into a thriving industry. Ira Honeywell, the first settler on the south bank, began to farm on the Ottawa side of the river in 1811.

**Bytown.** After the War of 1812, the British feared another war with the United States. As a result, they sought a way to send gunboats and supplies from Montreal to Lake Ontario without passing near U.S. territory. To carry out this project, the British sent the Royal Engineers under Lieutenant Colonel John By to build the Rideau Canal. A community known as Bytown grew up around By's headquarters.

Frequent conflicts between Irish canal workers and French-Canadian lumbermen made Bytown a stormy place during its early years. The lumber trade on the Ottawa River had begun in 1806, when Wright took the first raft of processed timber down to the St. Lawrence River. Bytown became a center of this trade. Sawmills and other lumber industries sprang up and, by 1837, the population had reached 2,400. Bytown was incorporated as a town in 1830. It became a city in 1855, and the people changed its name to Ottawa. The community had a population of about 10,000 that year.

**Capital of Canada.** Upper and Lower Canada (the southern parts of present-day Ontario and Quebec) joined in 1840 and formed the United Province of Canada. For the next 17 years, the legislature debated the question of a permanent capital. Meanwhile, Kingston,
Montreal, Quebec, and Toronto each served as capital. Canada referred the decision to Queen Victoria in 1857, and she chose Ottawa because of its beauty and location. Ottawa lay on the boundary of what had been Upper and Lower Canada. Yet the city was far enough from the United States to protect it from attack.

In 1867, Ottawa became the capital of the newly formed Dominion of Canada. Its population had then reached 18,000. The city grew in a disorganized fashion, with numerous railroads crisscrossing through the center of town to accommodate the lumber trade. In 1896, Prime Minister Wilfrid Laurier called for a beautification program to make Ottawa the "Washington of the North." Three years later, the Ottawa Improvement Commission was formed to carry out this project.

The 1900's. In 1900, a great fire destroyed many houses, leaving a large number of Ottawa's 60,000 people homeless. But by 1912, the city had been rebuilt and its population had reached 90,000.

The Federal District Commission replaced the Ottawa Improvement Commission in 1927. Ten years later, Prime Minister W. L. Mackenzie King appointed Jacques Gréber, the Paris city planner, to replan Ottawa. But World War II broke out in 1939 and interrupted the project and Gréber returned to France. Ottawa became the center of Canada's war effort.

After the war, Gréber went back to Canada. In 1951, Parliament accepted his plan to beautify Ottawa. The Gréber Plan brought about significant changes. Ottawa removed 32 miles (51 kilometers) of unattractive railroad tracks and relocated the railroad station to the east edge of the city. It set aside land for a belt of parks around the capital. The commission also developed 88,000-acre (35,600-hectare) Gatineau Park just north of Ottawa. Instead of grouping all government offices in one area, the plan called for new government buildings on the outskirts of the city.

The National Capital Commission replaced the Federal District Commission in 1959. The new commission has the responsibility of acquiring land for beautification purposes. It set up a national capital region of 1,800 square miles (4,660 square kilometers)—one 900-square-mile (2,330-square-kilometer) area in Ontario and another in Quebec. In the 1960's and 1970's, the commission created beaches and parks within the capital region. At the same time, the area's rapidly growing computer software and electronics industries built research facilities and factories.

In 1962, Ottawa established the Commercial and Industrial Development Corporation—now the Economic Development Corporation—to promote economic growth in the capital. This government corporation created 12 industrial parks in Ottawa during the late 1960's and early 1970's.

In 1973, the city repealed a law that had limited the height of buildings in the downtown area. As a result, larger buildings began to be constructed in Ottawa. City leaders predicted that the additional apartment dwellers and office workers in the new buildings—along with commuters from the growing suburbs—would strain Ottawa's transportation system. The provincial government announced a plan to avoid this problem by helping the city government build a new bus system. Much of the system is reserved for buses only. The plan called for Ontario to pay 75 percent of the cost of the project. Construction of the system began in 1981, and new parts are continually added.

In 1999, the Ontario legislature passed a law to create a new, enlarged city of Ottawa. The new city came into being on Jan. 1, 2001. It includes the urban and rural areas that had been part of the region of Ottawa-Carleton and the municipalities of Cumberland, Gloucester, Goulbourn, Kanata, Nepean, Osgoode, Ottawa, Rideau, Rockcliffe Park, Vanier, and West Carleton. Alje H. Kammenga

Ottawa, University of, or Université d'Ottawa, is a coeducational school in Ottawa, Canada. It is supported by the province of Ontario. It was operated by the Roman Catholic Oblates of Mary Immaculate until 1965, when control was transferred to an independent board of governors. The university's administration, instruction, and research are conducted in French and English. The university has faculties (colleges) of administration, arts, education, engineering, health sciences, law, medicine, science, and social sciences. In addition, the university also has a school of graduate studies, which offers 79 programs.

The University of Ottawa was founded as the College of Bytown in 1848. It received a civil charter in 1866 and a papal charter in 1889. In 1965, its faculties of theology and canon law were grouped to form Saint Paul University, which is federated with the University of Ottawa.

Critically reviewed by the University of Ottawa

Ottawa River is the chief branch of the St. Lawrence River and one of the most important streams of Canada. Great quantities of lumber float down the Ottawa from forests in the north.

The river begins in Quebec, about 160 miles (257 kilometers) north of the city of Ottawa. For location, see Quebec (terrain map). It flows west to the Quebec-Ontario border, and forms the border as it flows southeast. The city of Ottawa, Canada's capital, stands along the river. The river ends its 696-mile (1,120-kilometer) course north of Montreal, where it empties into the St. Lawrence River.

Rapids and falls along the river make it unnavigable for large ships. But the rapids and falls develop 1.5 million kilowatts of electric power a year. Chaudière Falls, north of the city of Ottawa, is the largest waterfall on the river.

Dams and slides for large logs have been built on the Ottawa to aid the lumber industry. Canals built along the river once aided shipping. But they are now used only for pleasure boats. The Rideau Canal system connects the Ottawa River with Lake Ontario. The river was an early canoe route to the interior of Canada. The French explorer Samuel de Champlain explored the river during the early 1600's.

Otter is a member of the weasel family. Otters live close to water and spend much time in it. They are expert swimmers and divers and can stay underwater for three or four minutes. The animal moves awkwardly on land.

Otters live on all the continents except Australia and Antarctica. Most otters weigh from 10 to 30 pounds (4.5 to 14 kilograms) and grow from 3 to 4 3/4 feet (0.9 to 1.4 meters) long. The giant otter of South America may measure up to 7 feet (2 meters) long. Otters live along rivers, streams, lakes, and coastal waters,
The North American otter lives in burrows along the banks of rivers and feeds primarily on fish and crayfish. The animal is a swift and graceful swimmer but moves awkwardly on land.

or in marshes. This article is about otters that live in fresh waters. For information about sea otters, which live in the Pacific Ocean, see the article on Sea otter.

Body. An otter has a small flattened head; a long, thick neck; and a thick tail that narrows to a point. Special muscles enable the animal to close its ears and nostrils tightly to keep water out. Elastic webbing grows between the otter’s toes. In most species, the webbing is extensive enough to help the animals swim swiftly.

Otters, like beavers and muskrats, have long coarse guard hairs that cover and protect the short, thick underfur. This underfur traps air and keeps the otter’s skin dry. In some species, a layer of fat under the skin insulates the otter from the cold. An otter’s fur varies in color from brownish-gray to dark brown when dry, and appears darker when wet.

Otters often use their paws to handle objects. They hold and play skillfully with such things as stones and small shellfish. Some African and Asian species that have only a little webbing between their toes can use the toes like fingers. Such clawless and small-clawed otters handle food in much the same way as raccoons. These otters feed on shellfish that live in shallow water. All otters have claws. Even the so-called clawless otter has short claws on the three middle toes of its hind feet.

The life of an otter. Otters eat crayfish, crabs, and fish. Although otters can sometimes catch such swift-swimming fish as trout, they generally capture slower fish. They also eat clams, frogs, insects, snails, snakes, and, occasionally, waterfowl. Otters are active the year around. Where people hunt them, they move about more at night than during the day. They hunt mostly alone, but sometimes they hunt in family groups.

Otters spend much time playing. They wrestle and romp and slide down steep muddy slopes in summer and down icy riverbanks in winter. Otters use a variety of sounds to communicate among themselves. All species have a warning growl. In addition, otters use various kinds of chirps, chuckles, screams, and squeals to express their feelings to other otters.

Most otters make their homes in burrows in riverbanks or under rocky ledges, or in abandoned dens of other animals. Most female otters give birth to two or three young at a time. The babies, called cubs or pups, are born blind. The young do not swim until they are several months old. People hunt otters for their valuable and beautiful fur. Certain species, especially the giant otter, are in danger of becoming extinct.

Scientific classification. Otters belong to the weasel family, Mustelidae. The North American otter is Lutra canadensis. The giant otter is Pteronura brasiliensis. The clawless and small-clawed otters form genus Aonyx. The clawless otter is classified A. capensis. The small-clawed otter is classified A. cinerea.

Joseph A. Davis

Otter hound is a breed of dog that was developed in Britain for the sport of hunting otters. It has a thick, rough coat, with an oily undercoat that enables it to stay in cold water for long periods. Its feet are slightly webbed, which helps make the dog a good swimmer. A male otter hound stands about 24 to 27 inches (61 to 69 centimeters) high at the shoulder, and weighs from 75 to 115 pounds (34 to 52 kilograms). Females stand about 22 to 26 inches (56 to 66 centimeters) high and weigh 65 to 100 pounds (29 to 45 kilograms). The otter hound’s color ranges from grizzled blue and white to sand, with black and tan markings.

The breed probably originated during the 1300’s. Its ancestry is unclear, but many breeders believe the otter hound was developed from the Vendee hound of France. Others believe it originally came from the bloodhound. Critically reviewed by the American Kennel Club

Otto I (1815-1867), was the first king of Greece after the Greeks won their independence from the Ottoman Empire (now Turkey) in 1830. France, Britain, and Russia—who had helped Greece win independence—named Otto king in 1832, and he ruled from 1832 to 1862. Otto was an unpopular ruler. He failed to move toward the realization of the “Great Idea,” which sought to liberate all Greeks still under Ottoman rule in such territories as Crete, Thessaly, and Macedonia.

Otto and the Greeks were prepared to join the Russians against the Ottoman Turks during the Crimean War (1853-1856). Britain and France sent troops to Greece to prevent it. The Greeks blamed Otto for this failure and deposed him in 1862. During his reign, Otto rebuilt Athens, established the first Greek university, and refounded Sparta. Otto I was born in Salzburg, Austria, as Otto Friedrich Ludwig, a prince of Bavaria (now part of Germany). John A. Kousoulides

See also Greece (Otto I).
Otto I, the Great (912-973), a German king, was the first emperor of what became known as the Holy Roman Empire. He followed his father, Henry I, as king of Germany in 936. Otto's father had actually ruled only his own duchy of Saxony, but Otto tried to rule all Germany.

In 951, Otto crossed the Alps and declared himself king of Italy. He was forced to return to Germany when the other German princes began a series of revolts. At the same time, the Slavs in Poland and Bohemia revolted, and the Magyars, or Hungarians, invaded Germany. Otto crushed the Magyars in the battle of the Lech River in 955. The Poles and Bohemians were forced to accept his rule. Otto was able to replace most of the rebellious German princes with members of his own family. The young king of Arles, or Burgundy, also had to accept German rule. Otto then turned his attention toward Italy. He married the widow of an earlier Italian king and defeated a rival for the throne. In 961, Otto crossed the Alps to put down an uprising in Rome. For this service, Pope John XII crowned him emperor of what was later known as the Holy Roman Empire. Otto was born in Quedlinburg.

Jonathan W. Zophy

See also Holy Roman Empire.

Otto II (955-983), a German king, was the second emperor of what became known as the Holy Roman Empire. He succeeded his father, Otto I, also called Otto the Great, in 973. Otto II's claim to the throne was challenged by his powerful cousin Henry the Wrangler, Duke of Bavaria. But by 978, Otto had defeated Henry and had named an ally to replace Henry as duke.

Otto II defended his borders against Slavs to the east, Danes to the north, and the French to the west. Beginning in 980, Otto II tried to extend his power into southern Italy. Muslims also were seeking control of the region at that time, and they defeated Otto near Crotone in 982. Danes and Slavs in the northern part of the empire then revolted and regained lands that they had lost to Otto I.

Otto II was born in Saxony. Along with his mother, Adelaide, and his wife, the Byzantine princess Theophano, he promoted the arts and church reform. After Otto II's death, Adelaide and Theophano ruled on behalf of his infant son, Otto III.

Jonathan W. Zophy

Ottoman Empire was the most powerful empire in the world during the 1500s and 1600s. At its height, it controlled what is now Turkey and parts of northern Africa, southwestern Asia, and southeastern Europe. The empire began about 1300 and lasted until 1922. The Ottomans were nomadic Turkish tribes that migrated to the Middle East from central Asia. The term Ottoman comes from Osman, also called Othman or Uthman, the founder and first sultan (ruler) of the empire.

Before the arrival of the Ottomans, the Byzantine Empire had occupied parts of Asia Minor (now Turkey) and southeastern Europe for almost 1,000 years. That empire ended in 1453, when the Ottomans conquered the Byzantine capital of Constantinople (now Istanbul). They made the city their capital. By the mid-1500s, the Ottomans ruled Asia Minor, the Balkans, and parts of northern Africa and present-day Iran, Saudi Arabia, and Syria. The Ottomans were Muslims, and they spread their religion, Islam, throughout the empire.

The Ottoman Empire slowly declined only after 1700, when it was faced with the emerging powers of Europe. When World War I began in 1914, the Ottoman Empire consisted of only Asia Minor, parts of southwestern Asia, and part of the Balkans. The Ottomans were defeated in the war, and the empire came to an end in 1922.

Ways of life

People of the Ottoman Empire, in addition to Turks, included many Arabs, Armenians, Greeks, and Slavs. The official language was Ottoman Turkish. The empire had two classes of people. The ruling class paid no taxes and included the imperial family, owners of large estates, and military and religious leaders. The rest of the people were peasants and craftworkers who did pay taxes. The sultan was responsible for protecting them against invasion and abuse by his ruling class. The profession and status of most individuals could be determined by the color and style of clothing and the size of the turban or other headdress they wore.

Almost all the women of the Ottoman Empire lived restricted lives. Islamic law permitted a man to have as many as four wives at a time. Muslim women lived most of their lives in seclusion, usually in a separate section of a household. This section was called a harem (see Harem). Some women gained power within their harem and had great influence over their husbands and sons. Muslim women also were required to wear veils in public. Many similar restrictions affected non-Muslim women as well.

Most Muslims strictly followed the rules of Islam as set down in their holy book, the Quran (see Islam [Teachings and practices]). However, the Ottomans allowed all religious groups to practice their own faiths. Christians and Jews made up the largest non-Muslim groups. Each religious group, including the Muslims, formed a millet (nation), whose leader represented its members before the government.

Cultural life. Neighborhood mosques (Muslim houses of worship) served as both religious and social centers for Muslims. Other millets had their own religious ceremonies and social events. The Ottomans adopted many styles of Byzantine and Persian art and literature. Major Ottoman contributions came in the fields of architecture, carpet weaving, and tile making.

Ottoman education emphasized religious studies. Beginning in the 1300s, boys attended schools in mosques. The best students went on to high schools called medreses. Girls began to go to elementary school in the mid-1800s. Secular (nonreligious) education at the high school and university levels began about the same time.

Economy. Most of the people of the Ottoman Empire worked as farmers. Grain was grown in fertile areas of Egypt, Syria, and lands surrounding the Black Sea. Craftworkers and merchants practiced their trade in the cities and towns.

The Ottoman Empire gained great wealth through trade. Some of the busiest trade routes between Asia and Europe ran through the empire. Merchandise offered in the markets of Ottoman cities included Chinese porcelains, European woolens, Persian silks, and spices from Asia.

Government. The Ottoman sultans made all important governmental decisions for the empire. The sultans appointed officials to collect taxes and to keep peace.
within the empire. The powers of the sultans were limited. For example, the rulers needed the support of the army to maintain their position. New laws were also subject to the approval of the empire's chief religious judge, the grand mufti, before they could take effect.

Until the 1630's, the oldest or favorite son succeeded to the throne upon the death or capture of a sultan. After the 1630's, it became common for the successor to be the oldest surviving male member of the family. Some sultans removed threats to their throne by murdering potential rivals or confining princes to the royal palace.

History

The beginning of the empire. The Turkish tribes led by Osman began to expand their small territory in the northwest corner of Anatolía (now Turkey) during the late 1200's. In 1326, the tribes captured the city of Bursa, which had been part of the Byzantine Empire. In the late 1300's, the Ottomans formed a group of highly trained soldiers called Janissaries (see Janissaries).

Expansion and decline. By the mid-1400's, the Ottomans had conquered the entire Byzantine Empire except for the city of Constantinople. Ottoman troops, led by Sultan Mehmet II, captured Constantinople in 1453.

Under Mehmet II, or Mehmed II, the Ottomans also conquered much of southeastern Europe and territory near the Black Sea. They took over Syria in 1516 and Egypt in 1517. The empire reached its peak of power and wealth under Sultan Süleyman I, who ruled from 1520 to 1566. His armies conquered Hungary, northern Africa, and territory on the east coast of the Red Sea down to what is now Yemen.

In 1571, naval forces from Spain, Venice, and the Papal States of Italy almost destroyed the Ottoman fleet in the Battle of Lepanto. But the navy was rebuilt, and the empire continued to grow. In 1683, Austrian and Polish troops turned back an Ottoman attack on Vienna, Austria. This defeat ended the empire's territorial expansion.

During the next 200 years, many nations won independence from Ottoman rule. Government corruption, oppressive taxation, inflation, and weak sultans also contributed to the decline of the empire.

The empire ends. In 1908, a group of Ottoman military officers called the Young Turks forced Sultan Abdülhamit II to restore the empire's constitution, which guaranteed an elected parliamentary government. The constitution had been adopted under Abdül-

During the 1600's, it was the world's largest empire. It had its capital in Istanbul and covered parts of Eastern Europe, the Middle East, and North Africa.

The empire declined in the 1700's and 1800's and collapsed during World War I (1914-1918). Turkey was formed in 1923 from the remaining territory.
moved to the city in search of work. Samuel Decalo

**Oubangui River.** See Ubangi River.

**Ouija board,** *WEE juh or VEE jee,* is a device used to supposedly ask questions of the spirits of the dead and receive answers from them. People who believe seriously in the Ouija board use it at gatherings called *séances.* Other people use the Ouija board for fun as a game.

A Ouija board has various symbols printed on its surface. These symbols include the letters of the alphabet, the numbers from 1 to 9 and 0, and the words *yes* and *no.* A smaller, three-legged board serves as a pointer.

Two or more people hold a Ouija board on their laps and press their fingers lightly on the pointer. One of them asks a question. The pointer supposedly answers by indicating a word or a number or by spelling out words. According to people who believe in the Ouija board, spirits guide the pointer. Others think the fingers of the questioner influence the pointer. The Ouija board was invented about 1890 by William Fuld of Baltimore. Its name comes from the French word *oui* and the German word *ja,* both of which mean *yes.* Alan Dundes

**Ounce.** See Snow leopard.

**Ounce** is a unit of weight or volume used primarily in the United States. As a unit of weight, it is used to measure *mass* (the amount of matter in an object) or force. In commercial and everyday use, the term *weight* is understood to mean mass, and the ounce is used as a unit of mass. In science and technology, *weight* refers to the gravitational force on an object, and so the ounce is also used as a measure of that force.

In the *avoirdupois* system of weights, there are 16 ounces in a pound. As a unit of force, the avoirdupois ounce equals 0.278 newton in the metric system; as a unit of mass, 28.350 grams in the metric system. This ounce also equals 437.5 grains of mass. The *troy weight* system, used throughout the world to measure the mass of precious metals, has a heavier ounce. The troy ounce equals 31.103 grams, or 480 grains. In the troy weight system, there are 12 ounces in a pound.

As a measure of liquid volume, one *fluid ounce* equals 29.574 milliliters. There are 32 fluid ounces in a liquid quart. Michael Dine

**Outback** is a term that refers to the rural interior of Australia and its unique characteristics. Some people use the term *outback* to describe all thinly populated areas away from Australia's coastal cities. Others apply the term to only those areas with low rainfall. The land and climate in much of the outback are harsh and variable. Many people associate life in the outback with a sense of adventure, individualism, and isolation.

Millions of years of weathering and erosion have flattened the outback's landscapes and reduced the quality of the soil. Most mountains in the region stand less than 3,900 feet (1,200 meters) tall. Large deserts with plant-covered sand dunes stretch across much of the outback. Since the late 1800's, large areas have been used for grazing sheep and cattle. The outback also has rich mineral resources, and mining is an important activity.

The outback is famous for its wide variety of unusual wildlife. The region's plants and animals include spinifex grass and eucalyptus and acacia trees; kangaroos and other marsupials; and large flightless birds called emus.

Less than 10 percent of Australia's people live in the outback. But many Australian Aborigines live there, usually in small, isolated communities or on livestock *stations* (ranches). Outback residents lack easy access to health care and education. As a result, they generally have poorer health and fewer career opportunities than people in the cities. A special aviation service called the Royal Flying Doctor Service provides medical treatment to people in remote areas. Also, schools of the air help students in isolated regions communicate with teachers using radio, telephone, and computer equipment.

The word *outback* comes from the phrase "out in the back country." This saying was first used in the 1800's to describe Australian frontier areas where the British colonial governments had little control. Stuart Pearson

**Outcault, OWT kawlt, Richard Felton** (1863-1928), was an American cartoonist. He created the first comic strip that gained widespread popularity. This weekly strip, called "Hogan's Alley," first appeared in 1895 in *The New York World,* a New York City newspaper. The strip quickly became an immense success.

The main character of "Hogan's Alley," a boy named Mickey Dugan, wore a long gown that, beginning in early 1896, was colored yellow. As a result, the character became known as the Yellow Kid. Later in 1896, "Hogan's Alley" was renamed "The Yellow Kid." Still later that year, Outcault accepted an enormous salary from the *New York Journal* to draw the strip for it. *The New York World* hired another artist to draw "The Yellow Kid," and the papers began a sensational rivalry. Other newspapers called them the "Yellow Kid journals." The term *yellow journalism,* meaning a highly sensational kind of newspaper writing, was symbolized by "The Yellow Kid" comic strip. Outcault was born on Jan. 14, 1863, in Lancaster, Ohio. Charles P. Green

**Outer Mongolia.** See Mongolia.

**Outlaw.** See Bandit with its list of Related articles.

**Outline** is a short summary of the main topics or principal ideas of a written work or a speech. A good outline serves as a useful tool for a reader or a writer. A reader can outline written material to discover the structure of the author's argument and to determine its strengths and weaknesses.

A writer uses an outline primarily to organize ideas about a subject. The procedure for making such an outline is the same, whether the outline is short and simple or long and complicated. First, list the important points about the subject. Next, classify the items on the list into meaningful groups. Then decide on a method of organizing the groups to present the information clearly and effectively. For example, move from the least important to the most important points or from arguments in favor of a position to arguments against it.

A formal outline may take the form of a **topic outline** or a **sentence outline**. A topic outline summarizes the chief topics and subtopics of the piece in brief phrases. A sentence outline uses complete sentences for each topic and subtopic. Most formal outlines have a thesis statement that identifies the argument or subject of the outline, followed by topic headings and indented subheadings.

Here is an example of a topic outline:

Thesis statement: There are better reasons for not buying a car than for buying one.

I. **Reasons for buying a car**
   A. Convenience
   B. Status

II. **Reasons for not buying a car**
   A. Inconvenience
      1. High cost of fuel
      2. Increasingly crowded roads
      3. Parking a growing problem
         a. Urban areas unpredictable
         b. Weather unpredictable
   B. Hazards
      1. Highway systems inadequate
      2. Possibility of accidents
   C. Poor financial investment
      1. Initial investment
         a. High taxes
         b. High interest rates
      2. Continuing investment
         a. Fuel
         b. Equipment
         c. Maintenance
      d. Fees to government agencies

Other examples of topic outlines may be found in World Book at the end of such articles as United Kingdom, Bird, and American literature. The Public speaking article uses a sentence outline. William E Coles, Jr.

**Outrigger** is either of two kinds of boats or two kinds of boat devices. In the Indian and Pacific oceans, an outrigger is a float attached to certain rowing canoes. The canoes are also called outriggers. The float is a long log that runs parallel to the boat and is linked to it by a frame. The float acts as a counterbalance to prevent the canoe from tipping over. A canoe that has two floats, one on each side, is called a double outrigger.

In the United States, outrigger refers to brackets that extend from the sides of certain small, narrow racing boats called shells. The brackets support the oars. The boats that have such brackets are sometimes called outriggers. Octavia N. Cobbens

See also Catamaran.

**Outward Bound** is an international educational organization that provides challenging wilderness experiences as courses of study. These experiences are intended to contribute to the self-discovery and personal growth of the participants.

Outward Bound offers courses to anyone more than 14 years old and in good health. Most of the courses last from 21 to 26 days and include such activities as backpacking, rock climbing, canoeing, sailing, and cross-country skiing. A small group of people take a course together. Each person, working with the others, must solve various problems in an unfamiliar wilderness environment. Outward Bound believes that dealing with these problems increases a person's self-confidence, self-awareness, and appreciation of others.

The first Outward Bound school was established in 1941 in Aberdovey, Wales, near Aberystwyth. Kurt Hahn, a German educator, founded it as a survival program for British sailors during World War II. The organization's first school in the United States was started in 1962 near Aspen, Colorado. Outward Bound has schools in more than 50 countries, including seven in the United States. Its U.S. headquarters are in Garrison, New York.

Outward Bound USA

**Ouzel.** See Dipper.

**Ovarian cancer** is uncontrolled multiplication of cells of the ovaries, a pair of female sex organs that store and release eggs. The ovaries also secrete estrogen and progesterone, the female sex hormones. Ovarian cancer occurs most often in women over age 60. The disease is more common among women in developed countries and relatively rare among women in Asia and many Third World countries. A high fat diet, early onset of menstruation, late menopause, never being pregnant, and having a close relative with the disease are all factors that may increase an individual's risk of developing ovarian cancer.

In the early stages of ovarian cancer, when the chance for successful treatment is greatest, the disease causes few or no symptoms. By the time symptoms develop, the cancer is often in a more advanced stage. Symptoms of ovarian cancer include discomfort or a feeling of fullness in the abdomen, loss of appetite, and unusual vaginal bleeding.

If ovarian cancer is suspected, doctors may begin by performing a blood test. Cancers of the ovary may produce a protein called CA 125, which can be measured in the blood. Elevated levels of CA 125 occur in about 80 percent of cases of ovarian cancer. In order to make a definite diagnosis, however, physicians must perform a procedure called a biopsy. In a biopsy, a surgeon removes a sample of ovary tissue. Experts then examine the tissue with a microscope, looking for cancer cells. If the biopsy reveals cancer, doctors may order additional tests to determine the extent of the disease. These tests include computed tomography (CT) scans of the abdomen and pelvis, and X rays of the chest and other organs.

The treatment for ovarian cancer usually starts with surgical removal of the ovaries and nearby tissues, including the fallopian tubes and often the uterus.
tient may also receive chemotherapy (drugs that kill cancer cells). Patients whose cancer has not spread have an excellent chance of being cured. Physicians often monitor the level of CA 125 in the blood of patients to detect any recurrence of the cancer.

Marc B. Garnick

**Ovary.** OH vahtr ee, is either of a pair of female sex organs that store and release eggs. The ovaries also secrete estrogen and progesterone, the female sex hormones. The human ovary is oval in shape and about the size of an unshelled walnut. One ovary is located on each side of the uterus, at the base of the abdomen.

At birth, each ovary contains about 400,000 immature eggs. About 400 of these eggs will mature and be released during a woman’s childbearing years. During the first half of each menstrual cycle, one of the eggs matures. Also during this time, the ovaries release estrogens, which cause the lining of the uterus to thicken in preparation for pregnancy. **Ovulation** (the release of the mature egg) occurs about midway through the menstrual cycle.

After ovulation, the ovary that released the egg secretes progesterone, which maintains the uterine lining, as well as estrogens. If the egg is fertilized, a pregnancy begins. The ovary and placenta—an organ that develops early in pregnancy—secrete progesterone and other hormones, and the menstrual cycle stops until after the baby has been born. If the egg is not fertilized, the ovary stops producing progesterone about 14 days after ovulation. The egg and the uterine lining then pass out of the body during menstruation.

Between the ages of 45 and 55, most women stop menstruating and enter a period called menopause. The ovaries gradually stop functioning and shrink to about the size of a pea.

**Oven.** See Range; Cooking (Methods; History).

**Ovenbird** is a common American bird that belongs to the family of warblers. The ovenbird looks like a small thrush. It is about 6 inches (15 centimeters) long and has a brownish olive-green back, dull orange crown, and a white breast spotted with black. Its song sounds like the word teacher, repeated with increasing loudness. The ovenbird is often called the teacher bird.

The ovenbird nests from Oklahoma to Georgia, and north to Manitoba and Labrador. Its name comes from the shape of its nest, which looks somewhat like an old-fashioned rounded oven. The ovenbird hides its nest on the forest floor. It lays four to six white eggs, speckled with cinnamon-brown. It eats mostly insects.

Sandra L. Vehrencamp

**Scientific classification.** The ovenbird belongs to the tribe Parulini in the subfamily Emberizinae, family Fringillidae. Its scientific name is Seiurus aurocapillus.

See also Warbler.

**Overeaters Anonymous** is an organization for people whose eating habits disrupt their lives or threaten their health. Overeaters Anonymous uses the term compulsive overeating to describe many types of eating problems. For example, some members overeat regularly. Others eat too much, then starve themselves or try to eliminate the excess food from their bodies by vomiting or using laxatives. The organization has members in every weight category, from underweight to overweight.

Overeaters Anonymous considers compulsive overeating an illness that can be managed. Members follow a recovery program adapted from Alcoholics Anonymous. This program encourages personal change through applying spiritual principles to life. Members gain support for their personal commitment by attending as many meetings as they wish. At meetings, members provide one another with fellowship, caring, acceptance, and practical advice. The organization’s head office is in Rio Rancho, New Mexico.

Critically reviewed by Overeaters Anonymous

**Overture, OH vahtrer chur,** is an instrumental composition that introduces a longer musical work, especially an opera. Some overtures, called concert overtures, are always performed as independent compositions.

The first overture was written in the 1660’s by the French composer Jean-Baptiste Lully. Lully opened his operas and ballets with French overtures, which were short pieces consisting of two sections. The first section was slow, and the second lively. The second section of the overture often ended with a brief return to the slow tempo.

In the 1690’s, Alessandro Scarlatti, an Italian composer, developed the Italian overture, also called the sinfonia. It consisted of three movements, of which the first was lively and written in the sonata form (see Sonata). The second was slow, and the third extremely fast. The Italian overture had an important role in the development of the symphony.

Overtures were revolutionized during the 1700’s by the German-born Christoph Willibald Gluck and by Wolfgang Amadeus Mozart of Austria. Gluck became the first major composer to use an overture to put the audience in the proper mood for an opera. Previously, the overture had no direct connection with the opera that followed it. Mozart continued Gluck’s ideas and established the overture as a single movement. The overtures written by Mozart served as models for overtures to future operas.

During the 1800’s, opera overtures were often performed separately at concerts. These performances inspired composers to write concert overtures. Most of these concert overtures were short pieces that musical-
ly told a story or set a mood. Popular concert overtures include the “1812” (1880) by Peter Ilich Tchaikovsky of Russia and the Academic Festival (1881) by Johannes Brahms of Germany. During the 1900’s, many concert overtures were written to be performed by school orchestras and bands.

The concert overtures composed by Felix Mendelssohn of Germany during the 1820’s and 1830’s led to the development of the symphonic poem in the mid-1800’s (see Symphonic poem). Another German composer, Richard Wagner, avoided the traditional overture in his operas of the mid-1800’s. Instead, Wagner used an orchestral piece called a prelude that led directly into the first scene of an opera. Many later composers used neither an overture nor a prelude in their operas.

R. M. Longyear

Ovid, *AHV ihd* (43 B.C.-A.D. 17?), was a great Roman poet. He became best known for his witty and sophisticated love poems.

Perhaps Ovid’s most famous work is the *Art of Love*, which is a kind of manual in verse on how to find and keep a lover. It consists of three books, two addressed to men and one to women, and all written in a humorous, satirical style.

Ovid believed that the *Metamorphoses* was his greatest work. It is a narrative poem beginning with the creation of the world and ending in Ovid’s time. The poem describes the adventures and love affairs of deities and heroes, with more than 200 tales taken from Greek and Roman legends and myths. Many of the stories involve a metamorphosis (transformation), such as the transformation of a woman into a bird. For information about some of the stories, see Arethusa; Narcissus; Pygmalion; and Pyramus and Thisbe.

Ovid’s other poems include the *Heroides* (Letters of Heroines) and the unfinished *Fasti* (*The Calendar*). The *Heroides* consists of 21 imaginary letters between famous women of mythology and their husbands or lovers. The *Fasti* deals with Roman religious festivals and customs and anniversaries of historical events.

Ovid was born on March 20, 43 B.C., in Sulmona, Italy. His full name was Publius Ovidius Naso. In A.D. 8, Emperor Augustus banished Ovid to an isolated fishing village on the Black Sea. Ovid wrote many poems pleading to return to Rome. But his pleas were ignored, and he died in exile.

Elaine Fanham

See also Latin literature (The Augustan Age).

Oviparous animal, *oh VIHP uhhr uhhs*, is an animal that reproduces by means of fertilized eggs that develop outside of the mother’s body. In viviparous animals, eggs are fertilized and develop inside the parent. Most vertebrates (animals with backbones) are oviparous, although there are exceptions. For example, certain types of fish, sharks, lizards, and snakes, and all mammals except for the platypus and the echidna, are viviparous.

George B. Johnson

See also Viviparous animal.

Oviraptor, *OH veeh RAH tuhr*, was a small meat-eating dinosaur that resembled an ostrich. It lived in what is now central Asia between 90 million and 65 million years ago.

The dinosaur grew about 6 feet (1.8 meters) long. In many individuals, a bony crest crowned the top of the head. Although Oviraptor was a meat-eater, it had a beaked mouth with no teeth. Only a bony peg in the roof of its mouth could have served to stab or crush food. The dinosaur ran swiftly on long hind legs, and it could grasp prey with the large claws on its forelimbs.

Oviraptor was discovered in the 1920’s. It received its name, which means egg robber, because people believed it primarily ate the eggs of other dinosaurs. Today, however, scientists are uncertain about Oviraptor’s diet. The dinosaur probably ate shellfish, or possibly small reptiles or eggs.

In 1993, fossil hunters found a nearly complete skeleton of a female Oviraptor lying on top of its nest of eggs. This fossil was preserved in exactly the same position as that of a modern bird. The Oviraptor sat in the middle of its ring of eggs to keep them warm and protected. This discovery suggested that dinosaurs took better care of their young than previously believed. It also strengthened the view that birds are closely related to certain meat-eating dinosaurs.

David B. Weishampel

Owen, Robert (1771-1858), was a Welsh-born social reformer. He tried to prove as a businessman that it was good business to think of the employees’ welfare. He set up the famous New Harmony community in Indiana in 1825. Owen also pioneered in cooperative movements (see Cooperative [History]).

Owen was part owner and the head of the New Lanark cotton mills in Scotland in 1799. The Industrial Revolution had begun, and machines were replacing home sewing and weaving. New factories were rarely built with the comfort of the workers in mind. Wages were low, and women and children were not treated with consideration.

Owen organized a model community. Instead of employing children, he built schools for them. He kept his mills in good repair and tried to take care of his laborers’ needs. His successful mills impressed many visitors.

New Harmony. Owen wrote on the subject of proper social conditions and tried to interest the British government in building “villages of cooperation.” He thought these villages ought to be partly agricultural and partly industrial. He made up his mind to show they could succeed. He then bought the town of Harmonie, Indiana, and renamed it New Harmony. There he attempted to create a utopia (perfect society).

Owen believed in equal opportunity for all. His ideas in education were influenced by Johann Pestalozzi, a Swiss educator. Owen opposed mere book learning. He believed children also could be taught “correct ideas” by surrounding them with good examples. Owen lost popularity with some people because he held antireligious views.

Many of New Harmony’s residents eventually gave up Owen’s principles. In 1827, the community failed, and Owen returned to England.

Cooperatives, Owen retired from business to concentrate on his social theories. He lived in London in 1828. There, trades unions became interested
Owen, Robert Dale (1801-1877), was a social theorist and an American legislator. He worked with his father, social reformer Robert Owen, in model communities in Scotland (at New Lanark) and in the United States (at New Harmony, Indiana). He edited the New Harmony Gazette with Frances Wright. When the New Harmony community failed in 1827, Owen moved to New York City. He and Frances Wright edited the Free Enquirer and tried to organize the Workingmen's Party in 1829 in New York.

Owen returned to Indiana in 1832. He served in the state legislature from 1836 to 1839 and from 1851 to 1852. He was a member of the U.S. House of Representatives from 1843 to 1847. He served as minister to Naples from 1854 to 1858. Owen championed emancipation for black slaves and influenced President Abraham Lincoln's views. He was a freethinker in religion and a pioneer in advocating birth control and universal education. Owen was born on Nov. 9, 1801, in Glasgow, Scotland.

Owen, Ruth Bryan (1885-1954), was the first American woman chosen to represent the United States in another country. She served as U.S. minister to Denmark from 1933 to 1936. The United States did not have an ambassador to Denmark at the time. The first woman to serve as a U.S. ambassador to a foreign country was Eugenie Anderson, when she became ambassador to Denmark in 1949.

Owen was born on Oct. 2, 1885, in Jacksonville, Illinois, the oldest daughter of the well-known statesman, William Jennings Bryan. She served as a Democrat from Florida in the U.S. House of Representatives from 1929 to 1933. Owen served as alternate U.S. representative to the United Nations General Assembly in 1949.

Owens, Jesse (1913-1980), was an American track-and-field star. His performances during the mid-1930s in college and in the Olympic Games made him one of the most famous athletes in sports history.

Owens won four gold medals at the 1936 Summer Olympic Games in Berlin, Germany. He won the 100-meter and 200-meter races and the broad jump (now called the long jump), and he was a member of the winning American 400-meter relay team. He set Olympic records in the 200-meter race and in the broad jump. The performance of Owens, who was black, was embarrassing to Adolf Hitler, the ruler of Germany. Hitler and his followers were hoping that German athletes would prove that the Aryans—a term they used for Germans and certain other peoples of northern Europe—were superior to all other peoples.

Owens was born on Sept. 12, 1913, in Oakville, Alabama, near Danville. His given and family name was James Cleveland Owens. His nickname, Jesse, came from his initials. J. C. Owens was the son of a sharecropper. At the age of 7, he moved with his family to Cleveland. Owens excelled in track and field while attending Ohio State University from 1933 to 1936. At a college meet in Ann Arbor, Michigan, in 1935, he broke three world records and tied a fourth within 45 minutes. Owens set seven world records during his career.

Owens eventually went into the public relations business. He worked in community service, especially youth work. Owens traveled widely, giving many speeches that supported clean living, fair play, and patriotism. Owens believed that athletic competition could help solve racial and political problems.

Owensboro (54,067; met. area pop. 91,543), lies in western Kentucky, on the south bank of the Ohio River (see Kentucky [political map]). Factories there make automotive frames, chemicals, electrical goods, food products, furniture, liquor, and tobacco products. The city is the home of Brescia University, Kentucky Wesleyan College, and Owensboro Community College.

Owensboro was founded in the late 1790s as Yellow Banks and later renamed in honor of Colonel Abraham Owen, who died in the 1811 Battle of Tippecanoe. The city was incorporated in 1817. It is the seat of Daviess County. Owensboro's government is headed by a manager and a commission.
has a wingspread of 54 to 60 inches (137 to 152 centimeters).

**Appearance.** A person can recognize any owl at once by its large, broad head with a saucer-shaped ruff of feathers around the eyes. This ruff is called the *facial disk*. It serves to reflect sound to the owl's ear openings. In some species, the facial disk and the ear openings are very large. The eyes of most owls are large and are directed forward, unlike the eyes of most birds. For this reason, owls can watch an object with both eyes at the same time. Like people, they have binocular vision. But unlike people, owls cannot move their eyes in their sockets. Thus, they must move their heads to watch a moving object. Owls have long lashes on their upper eyelids, which they can close over the eyes. Owls' eyes make them look wise, and so the owl has long been a symbol of wisdom. The ancient Greeks believed the owl was sacred to Athena, their goddess of wisdom. Actually, blue jays, crows, jackdaws, and many other birds are probably smarter than owls.

Owls have short, thick bodies; strong, hooked beaks; and powerful feet with sharp claws called *talons*. Some owls have tufts of feathers on their heads. The tufts are often called "ears" or "horns." The feathers of owls are long, soft, and fluffy, and often make the birds seem larger than they are. The plumage is usually dull-colored, so that the bird may blend in with its surroundings.

**Way of life.** Owls can fly fairly fast. Their feathers muffle the whistling sound that most birds make when they fly. An owl can swoop down on its prey unheard. Some owls can see well enough in the daytime to hunt by day as well as by night. Other owls hunt only at night. Most night-hunting owls have keen vision in the dark. However, some owls have such sensitive hearing that they rely very little on vision. These owls can locate and catch mice, voles, and other small mammals in total darkness by listening to the rustling noise the animals make running through leaves on the forest floor.

Owls eat mostly mammals. The larger owls catch rabbits and squirrels, and the smaller ones catch many mice, rats, and shrews. Owls usually capture their food alive, but now and then they pick up animals that have been recently killed along highways. Some owls also hunt a few birds and insects. Other owls have been known to take fish from shallow waters. Like hawks, owls tear large prey into pieces when they eat it. But if the prey is small enough, they swallow it whole. They later cough up pellets of bones, fur, scales, and feathers, which they cannot digest. These pellets can be found under their nests and roosting places.

Owls are among the most useful birds to farmers. They destroy harmful rodents, such as voles and rats, and also rabbits, which often damage crops. They seldom take poultry, which are usually asleep and inside when owls come out to hunt.

Owls do not build elaborate nests. Their nests are usually old nests of hawks or crows, or crude structures in hollow trees, caves, underground burrows, barns, deserted houses, or belfries. Most female owls lay 3 or 4 eggs, but some lay as few as 1 or as many as 12 eggs. The eggs are nearly round and are white tinged with buff or blue.

Both male and female owls help care for their eggs and young. Young owls have a covering of thick white down. They stay in the nest for 10 to 12 weeks. The larger owls defend the nests against intruders, including people. They sometimes injure people by striking with their sharp talons.

**Important owls.** There are two families of owls: *barn owls* and *typical owls*. There are 10 species of barn owl. They live in most places except the colder regions. The *common barn owl* lives on all of the continents except Antarctica. In North America, it ranges from the latitude of southern British Columbia and southern Ontario south to Central America. The *common barn owl* is about 18 inches (46 centimeters) long. This owl is sometimes called the *monkey-faced owl* because its heart-shaped face, beady eyes, and amusing actions seem like those of a monkey. The common barn owl usually nests in a cave or hollow tree. It also may nest in a belfry or the dark places in a barn, which gives it its name.

Typical owls account for about 135 species. The *great horned owl* lives in many places throughout North America. It is common in the forests of the eastern and northern parts of the continent, and among cliffs and canyons of the dry regions in the West. It grows 2 feet (61 centimeters) long and is the only large owl of North America that has tufts of feathers on its head. Like other owls, it is heard more often than seen. It sounds like a barking dog in the distance—*whoa, hoo-hoo, whoa, whoo.*

The great horned owl has been known to kill and eat poultry. However, it helps prevent damage to crops by feeding on rabbits. The great horned owl chooses old crow or hawk nests in which to lay its eggs. Both males and females sit on the eggs at different times. The young great horned owls cannot fly until they are 9 to 10 weeks old.

The *barred owl* lives chiefly in woodlands in the eastern half of North America, from Canada south to Mexico. It is a bit smaller than the great horned owl and has no ear tufts. Brownish-gray bars run across its breast and the length of its belly. The barred owl deserves the name hoot owl more than any other. It gives a series of eight or more loud hoots, the last one ending with an *alt: whoo, whoo, whoo—whooh, whoo, whoo, whoo, whoo-ah.*

The best-known of the small owls are the *screech owls*. These owls measure about 10 inches (25 centimeters) long and are the only small owls with ear tufts. They eat mostly large insects. Most screech owls have from four to six young.

The *eastern screech owl* lives in woodlands east of the Rocky Mountains, from northern Canada to Mexico. Eastern screech owls may be reddish or grayish in color. These owls like to spend the day in hollow trees and to nest there. They may live in a birdhouse if it has a single compartment and an opening 3 inches (8 centimeters) or more across. They often use the trees along city streets and in parks. Eastern screech owls may give no signs that they are around until night. Then they give weird trembling calls and hollow whistles that run up and down the musical scale. Superstitious people think these sounds mean that death or disaster is near. Eastern screech owls eat mostly mice and other small rodents, insects, and sometimes birds.

The adult male *snowy owl* is usually pure white, al-
Some kinds of owls

Owls are good hunters. They see and hear well and can fly almost noiselessly. Many owls build their nests in hollow trees. Others nest on ledges of cliffs or in burrows in the ground. Owls are helpful to people because they eat mice, rats, and other pests.

Burrowing owl
*Athene cunicularia*
Found on plains of Western Hemisphere
Body length: 9 inches (23 centimeters)

Elf owl
*Micrathene whitneyi*
Found in Southwestern United States and Mexico
Body length: 5.7 inches (14 centimeters)

Great horned owl
*Bubo virginianus*
Found throughout North America
Body length: 24 inches (61 centimeters)

Snowy owl
*Nyctea scandiaca*
Found in Arctic
Body length: 20 inches (51 centimeters)

Barn owl
*Tyto alba*
Found on all continents except Antarctica
Body length: 18 inches (46 centimeters)
though it may have brown spots. It measures about 20 inches (51 centimeters) in length. The snowy owl breeds in the Arctic. It may move south in winter, sometimes as far as the Gulf of Mexico.

The long-eared owl is another woodland species. It nests in temperate regions of North America, Europe, Asia, and northern Africa. In North America, it flies as far south as Florida for the winter. The long-eared owl grows to about 16 inches (30 centimeters) long. The owl’s ear tufts are close together, and it has lengthwise streaks on the breast.

The northern saw-whet owl also lives in the woods. Its name comes from its rasping call. In the course of the year, this bird makes its home from Alaska and Nova Scotia south to Mexico. The saw-whet is often tame and can be captured by hand.

Several kinds of owls live in open country and hunt by day as well as night. The short-eared owl is about the size of the long-eared owl. It is buff colored all over with many brown streaks. The ear tufts are so short that they are not noticeable. The owl nests in the northern regions of North America, Europe, and Asia, but moves south in the winter. The owl also nests in the southern part of South America. It lives mostly on prairies, meadows, and marshes, and nests on the ground. The burrowing owl nests in the ground like a ground squirrel. This owl has long legs that help it walk about, and it can see well in daylight. Burrowing owls often live near colonies of prairie dogs because they frequently use old prairie dog burrows as nesting sites.

Scientific classification. Owls belong to one of two families, the barn owl family, Tytonidae, or the typical owl family, Strigidae. The scientific name for the common barn owl is Tyto alba. The barred owl is Strix varia; the eastern screech owl, Otus asio; the long-eared owl, Asio otus; the northern saw-whet owl, Aegolius acadicus, and the short-eared owl, Asio flammeus.

Owyhee Dam, oh WY hie, is one of the larger concrete arch gravity dams in the world. It lies on the Owyhee River in Oregon, about 11 miles (18 kilometers) southwest of Adrian, Ore., near the Idaho state line. The dam is 417 feet (127 meters) high and 830 feet (253 meters) long. It can store about 1.1 million acre-feet (1.4 billion cubic meters) of water. It forms a reservoir 52 miles (84 kilometers) long which stores water for irrigating about 16,000 acres (6,470 hectares) of land. This dam was built by engineers of the United States Bureau of Reclamation. It was completed in 1932 at a cost of $6,671,000.

Larry W. Mays

Ox. Oxen include domestic cattle, water buffalo, bison, musk oxen, brahman, yak, banteng, and other members of the bovine family. Most oxen first came from Asia and Europe. The musk ox and bison are natives of North America. South America, Australia, and Madagascar have no native oxen.

Oxen have heavy bodies, long tails, and divided hoofs, and they chew their cud. Their smooth horns stand out from the side of the head, and are curved.

Domestic oxen give meat, milk, and leather. Domestic oxen are very powerful work animals, and they serve as beasts of burden in some parts of the world.

Scientific classification. The different kinds of oxen belong to the bovid family, Bovidae. Domestic cattle are Bos taurus.

Oxalic acid, ahk SAL ihk, is a strong organic acid found in many vegetables and other plants. It occurs abundantly as its potassium salt in the sap of dock and other plants in the oxalis and rumex plant groups. It is found in spinach, rhubarb, tomatoes, grapes, and sweet potatoes. Oxalic acid is also produced in the body. It has been known since early times.

Industry uses oxalic acid in processing textiles, bleaching straw hats, and removing paint and varnish. It is widely used in chemistry as an analytical reagent. Oxalic acid forms substances called complexes with various metals, especially iron. For this reason, it is also used as a rust and scale remover.

The acid is prepared commercially by heating sodium formate with sodium hydroxide or by bubbling carbon monoxide gas into a concentrated sodium hydroxide solution.

Oxalic acid occurs as clear, colorless crystals, soluble in water. It is highly poisonous if swallowed. Its chemical formula is (COOH)₂H₂O, and it melts at 101.5 °C (215 °F). This formula is the dihydrate form, as shown by the two water molecules. When heated to 212 °F (100 °C), the crystals lose the water and have the formula (COOH)₂ (see Hydrate).

Roger D. Barry

See also Acid; Oxalis.

Oxalis, AHK suh ihh, is the name of a large group of plants that grow chiefly in South Africa and South America. There are about 850 species of oxalis. Many species grow as weeds. However, some species are cultivated as ornamental plants and are grown in hanging baskets, window gardens, or rock gardens.

Most kinds of oxalis grow from bulbs, from rootlike rhizomes, or from thickened underground stems called tubers. They have showy flowers that may be white or a variety of pastel colors. The leaves are shaped somewhat like clover leaves. Both the leaves and flowers close up at night. The leaves taste sour because they

An oxalis has clover-shaped leaves and colorful blossoms. The leaves and the flowers close up at night.
contain **oxalic acid**. The acid is so named because it comes from the oxalis plant. The leaves of some kinds of oxalis can be used in salads. One species of oxalis is cultivated in South America for its edible tubers.

August A. De Hertogh

**Scientific classification.** Oxalis belong to the wood-sorrel family, Oxalidaceae. They make up the genus Oxalis.

**Oxbow lake** is a crescent-shaped lake that forms when a river channel is cut off from the main stream. Such a lake forms when a river changes its course to a more direct path to the sea. The river leaves deposits of earth at either end of the curve, and these deposits eventually separate it from the main stream. Oxbow lakes are often rather shallow. They may become filled with sediments from river floods and decayed vegetation, and so disappear. Many oxbow lakes are found in Louisiana, Arkansas, and Mississippi along the Mississippi River and some of its slow-moving branches.

J. M. Coleman

**Oxen.** See Ox.

**Oxenstierna, UK suhn shair na, Axel Gustafsson** (1583-1654), a Swedish statesman, was friend and adviser to King Gustavus Adolphus. Oxenstierna’s brilliance as a statesman helped the king achieve great military victories. As chancellor, Oxenstierna directed Sweden’s political affairs from 1612 until his death. This period marked Sweden’s greatest influence in Europe.

Oxenstierna carried out important diplomatic missions for Gustavus Adolphus during the Thirty Years’ War (1618-1648), a struggle between Roman Catholics and Protestants. After Gustavus died in battle in 1632, Oxenstierna directed Sweden’s foreign affairs and provided vital leadership throughout the war. From 1636 to 1644, he headed the regency (temporary ruling group) that ruled Sweden during Queen Christina’s childhood.

Oxenstierna was born in Fånö, Sweden.

Theodore S. Hamerow

**Oxford, England** (pop. 115,000), is the seat of Oxford University. The university, which began to develop in the 1100’s, is the oldest British university (see **Oxford University**). The city lies between the rivers Thames and Cherwell, about 50 miles (80 kilometers) northwest of London (see England [political map]).

The original center of the city was probably a home for nuns that was founded in the 700’s. The home was on the present site of the cathedral at Oxford University. Oxford is now an important industrial center, with automobile factories on the outskirts of the city.

Peter R. Munnfield

**Oxford Movement** is the name given to a revival in the Church of England that began in 1833 at Oxford. A powerful sermon was preached by John Keble (1792-1866), who urged the people the evils that were threatening the church because of their indifference and ignorance. Two leaders joined Keble in the Oxford Movement. One was the brilliant John Henry Newman, and the other was the learned Edward B. Pusey (1800-1882).

These leaders preached and wrote for a number of years, seeking to impress on the people that the church was “more than a merely human institution; that it had privileges, sacraments, a ministry ordained by Christ; that it was a matter of the highest obligation to remain united to the Church.”

The leaders of the Oxford Movement wrote a series of essays called “Tracts for the Times.” These essays were widely read and the movement grew. But in 1841 Newman wrote a tract which was so decidedly Catholic that the Anglican bishops condemned it. In 1845, Newman joined the Roman Catholic Church, and was eventually made a cardinal.

The Oxford Movement had great influence upon the Anglican world, including the Episcopal Church in the United States. It revived faith in the church as the divine society, not to be controlled by the state. It made the office of the pastor more important. The movement increased the importance of tradition and the sacraments. It extended the work of the church among the poor in larger cities. In general, it also awakened church and laity to a broader view of their power and duty.

Peter W. Williams

**Cardinal; Wilberforce, Samuel.**

**Oxford University** is the oldest university in the United Kingdom and one of the world’s most famous institutions of higher learning. Oxford University started to develop during the 1100’s. It is in Oxford, England, about 50 miles (80 kilometers) northwest of London.

The university has over 13,000 students. It consists of 35 colleges, plus 5 private halls established by various religious groups. Three of the 5 private halls are for men only. Of the colleges, St. Hilda’s is for women, and the rest are for men and women. The coeducational colleges include All Souls, Christ Church, Jesus, Lady Margaret Hall, Magdalen (pronounced MAWD ihn), Nuffield, St. John’s, Somerville, and Trinity.

At Oxford, each college is a corporate body distinct from the university and is governed by its own head and fellows. Most fellows are college instructors called tu-
tors, and the rest are university professors, readers, and lecturers. Each college manages its own buildings and property, elects its own fellows, and selects and admits its own undergraduate students. The university provides some libraries, laboratories, and other facilities, but the colleges take primary responsibility for the teaching and well-being of their students.

**Educational program.** Each student at Oxford is assigned to a tutor, who supervises the student's course of study, primarily through *tutorials*. Tutorials are weekly meetings of one or two students with their tutor. Students may see other tutors for specialized instruction. They may also attend lectures given by university teachers. Students choose which lectures to attend on the basis of their own special interests and on the advice of their tutor.

The university, not the individual colleges, grants degrees. The first degree in the arts or sciences is the Bachelor of Arts with honors. Oxford also grants higher degrees, diplomas, and certificates in a wide variety of subjects.

The Rhodes scholarship program enables students from the United States, Canada, and many other nations to study at Oxford for a minimum of two years (see Rhodes scholarship). The British government grants Marshall scholarships to citizens of the United States for study at Oxford and other universities that are located in Britain.

**History.** During the 1100's, a university gradually developed from a number of schools in the city of Oxford. Its development was aided by a break in relations between England and France in 1167. Hostility between the two nations prevented English students from attending the University of Paris, and many of them went to Oxford instead. The university received its first official recognition in 1214.

The three oldest Oxford colleges—University, Balliol, and Merton—date from the 1200's. Twelve more colleges were founded between 1300 and 1555. The first colleges for women were established during the late 1800's. The university did not grant degrees to women until 1920.

**Oxidation,** *ahk suh DAY shuhn,* is a chemical reaction in which a substance loses electrons. The term originally referred to any chemical process in which a substance combines with oxygen. This definition of oxidation was formulated by chemists before they discovered that some reactions of this kind could occur without oxygen.

The electrons released during oxidation must be captured by another substance. Thus, oxidation is always accompanied by a reaction called *reduction*, in which a substance gains electrons. The combined transfer of electrons is often called a *redox process*. See Reduction.

Oxidation can be demonstrated by heating iron and sulfur together. In this case, each neutral iron atom (Fe) loses two electrons and becomes an iron ion (Fe⁺⁺). The chemical equation for the oxidation of iron can be written:

\[ \text{Fe} \rightarrow \text{Fe}^{2+} + 2e^- \]

The electrons released during oxidation are immediately picked up by sulfur atoms, resulting in the formation of sulfide ions (S²⁻). These sulfide ions combine with the iron ions to form the compound iron sulfide (FeS).

The rusting of iron is a common example of the original meaning of oxidation. Iron combines with oxygen in the presence of moisture to form rust. Another example is the formation of such air pollutants as nitrogen oxides and sulfur oxides. These substances form when oxygen combines with nitrogen in hot, fuel-burning automobile engines. Sulfur oxides form when oxygen reacts with sulfur in coal-burning furnaces.

Oxidation also occurs inside the human body when food molecules combine with inhaled oxygen to slowly produce carbon dioxide, water, and energy. The combustion of natural gas and other fossil fuels is a form of rapid oxidation.

Cathleen J. Hapeman

**Oxide,** *ahk suh DEYE,* is a chemical compound of oxygen with some other element. Oxides are commonly formed when the elements are oxidized. For example, burning the carbon present in coal or wood gives carbon dioxide (CO₂) and carbon monoxide (CO). Burning is rapid
oxidation. Carbon dioxide is also formed by slow oxidation processes in animal cells, and it is exhaled from the lungs. The rusting of iron is slow oxidation. Rust contains ferric oxide (Fe₂O₃).

Metallic oxides combine with water to form basic hydroxides, while nonmetallic oxides with water form oxygen acids. The oxides of sulfur and nitrogen are used to form sulfuric and nitric acids.

Sulfur dioxide and nitrogen oxides pollute the air when given off by automobiles, by factories, and by power plants that burn coal or oil. They also mix with moisture in the air to form sulfuric and nitric acids, which fall as acid rain (see Acid rain). Acid rain damages plants, wildlife, and certain building structures.

Calcium oxide is quicklime (CaO). When mixed with water it forms the slaked lime used in whitewash and plaster. Sand, which is important in glassmaking, is one form of silicon dioxide, called silica (SiO₂). Other forms of silicon dioxide are quartz, onyx, and opal.

Cathleen J. Hapeman

Oxnam, G. Bromley (1891-1963), was a bishop of the Methodist Church. He served as bishop of the Washington, D.C., area from 1952 to 1960, when he retired. Oxnam's books and speeches emphasized his liberal social beliefs. They favor justice for laborers and equal rights for all classes.

Garfield Bromley Oxnam was born in Sonora, California. Oxnam was ordained a Methodist minister in 1916. He taught at the Boston University of Theology from 1927 to 1928. Oxnam served as president of DePauw University in Greencastle, Indiana, from 1928 to 1936. He was bishop of the Omaha area from 1936 to 1940, of the Boston area from 1940 to 1944, and of the New York area from 1944 to 1952. Charles H. Lippy

Oxacetylene. See Acetylene.

Oxygen is a life-supporting gas and a chemical element. Nearly all living things need oxygen to stay alive. Oxygen combines with other chemicals in plant and animal cells to produce energy needed for life processes. Oxygen is also needed to make most fuels burn. During the burning process, oxygen combines with the fuel in a chemical reaction. Heat is released during the burning process.

Oxygen is one of the most plentiful chemical elements on the earth. It makes up about a fifth of the volume of air. Nitrogen makes up most of the other four-fifths. Oxygen is also found in the earth's crust and in water. This oxygen is not pure, but is combined with other elements. On the average, 100 pounds of the earth's crust contains about 47 pounds of oxygen. Nearly half of the weight of most rocks and minerals is oxygen. Every 100 pounds of water contains about 89 pounds of oxygen. Hydrogen makes up the other 11 pounds of water.

Chemical properties. Oxygen has an atomic number of 8 and an atomic weight of 15.9994. Its chemical symbol is O. Ordinary oxygen molecules, such as those that make up about 20 per cent of the atmosphere, have two oxygen atoms bonded together. This ordinary oxygen, O₂, is colorless, odorless, and tasteless. Oxygen molecules that have three oxygen atoms make up a gas called ozone, O₃. Oxygen combines with many other elements, forming compounds called oxides (see Oxide).

Ordinary oxygen changes to a pale blue liquid when cooled to its boiling point, −182.962 °C at atmospheric pressure. Oxygen liquefies at a higher temperature when the pressure is increased. At a pressure of 730 pounds per square inch (51 kilograms per square centimeter), oxygen liquefies at −118.8 °C. These values of temperature and pressure are oxygen's critical temperature and pressure. It is impossible to liquefy oxygen at a higher temperature at any pressure. Liquid oxygen is magnetic and can be held between the poles of a strong magnet. It freezes at −218.4 °C.

How oxygen supports life. Only a few kinds of living things, including certain germs, can live without free (chemically uncombined) oxygen, O₂. Human beings and the other land animals get oxygen from the air. Fish and most other water animals get dissolved oxygen from water.

Free oxygen enters a person's bloodstream through the lungs. It enters a fish's bloodstream through the gills. The blood carries oxygen to the cells of the body. In the cells, oxygen combines with chemicals obtained from food. Energy produced during this process makes it possible for each cell to perform its function in the body. Carbon dioxide is produced in the cells as a waste product (see Respiration).

Some people believe that breathing pure oxygen will lead to an early death. They think the body's cells will use oxygen too fast, causing a person to die of exhaustion. But in certain situations, breathing pure oxygen may be necessary. For example, pilots who fly at high altitudes, where the air is too thin to supply enough oxygen, breathe from tanks of pure oxygen.

Plant cells use oxygen in much the same way that animal cells do. Plant cells also make oxygen in the process of photosynthesis. During this process, the cells use the energy of sunlight to make sugar from carbon dioxide and water. Oxygen is produced as a by-product, and is released into the atmosphere. Scientists believe that all of the air's oxygen has been formed from water by this process over billions of years.

Other uses of oxygen. Oxygen has many uses in industry. Some steel is manufactured by the basic oxygen process. In this process, a stream of high-pressure oxygen blasts down on melted pig iron and burns out impurities. Welders mix oxygen with fuel in their torches to produce an extremely hot flame with a temperature of about 6000 °F (3300 °C).

Liquid oxygen, called LOX, is used in rockets propelled by liquid fuels. LOX combines with various fuels, including kerosene and liquid hydrogen, to produce the rocket's thrust (pushing force). LOX is also mixed with other fuels to make explosives for blasting.

Making oxygen. Most commercial oxygen is distilled from liquid air. During the distillation process, the nitrogen boils before the oxygen does, because nitrogen has a lower boiling point. As the nitrogen boils away, the liquid air is left with a greater concentration of oxygen. Commercial oxygen is stored in steel tanks at a pressure of about 2,000 pounds per square inch (140 kilograms per square centimeter), more than a hundred times the pressure of the atmosphere.

Small amounts of oxygen can be made by heating po
tassium chloride. A little manganese dioxide added to the potassium chloride speeds up the formation of oxygen.

**History.** Oxygen was discovered by two chemists working independently. They were Carl Scheele of Sweden and Joseph Priestley of England. Scheele's laboratory notes show that he prepared oxygen in the early 1770's by heating various compounds, including saltpeter and mercuric oxide. Scheele's experiments were not published until 1777. Priestley, however, had published his experiments with oxygen in 1775 and published further observations concerning the gas in 1777. He described how he prepared oxygen in 1774 by heating mercuric oxide.

Scheele called oxygen fire air. Priestley called it dephlogisticated air. In 1779, the French chemist Antoine Lavoisier named the gas oxygen. The word means acid producer. Lavoisier and others had found that oxygen is a part of several acids. Lavoisier incorrectly reasoned that oxygen is needed to make all acids. He combined the Greek words oxys (meaning sharp or acid and gig-noma/meaning producer) to form the French word oxygen. This word is oxygen in English.

**Oxygen tent** is a device that has been used in medicine for patients who require more oxygen than is normally contained in the air. Oxygen tents were once used extensively to treat oxygen deficiencies in infants and children. Physicians seldom use oxygen tents today.

Oxygen tents are made of plastic or other material through which oxygen cannot pass. Oxygen enters the tent through a hose. Some tents are dome-shaped hoods large enough to completely cover an infant. Others can cover an entire bed.

Newer methods of administering oxygen allow doctors and nurses to reach the patient more easily. Oxygen may be given through tubes inserted into the nostrils, or through a mask placed over the nose and mouth. Newborns may receive oxygen through a plexiglass hood placed over the head. Patients who have severe difficulty breathing may need machines called respirators (see Respirator). People with carbon monoxide poisoning may be placed in a hyperbaric chamber, an airtight compartment in which oxygen is provided at pressures greater than atmospheric pressure. Gerald B. Merenstein

**Oyster** is a type of shellfish that provides an important source of food and pearls. The soft, edible body of an oyster is protected inside a hard, two-piece shell, which is usually irregular in shape. An oyster spends all except the first few weeks of its life attached to rocks and other hard surfaces on the ocean bottom. Oysters are found in relatively calm waters of mild to tropical coastal oceans, where they often form large reefs.

People began eating oysters thousands of years ago. About 100 B.C., the ancient Romans raised oysters on "farms" along the coast of Italy. Later, Roman settlers in England collected oysters along the coast. In winter, they placed the shellfish in cloth bags filled with ice and snow and sent them to Rome. Today, oyster farms are common along parts of the United States and European coasts.

Oysters—like clams, scallops, and some other shellfish—are a type of mollusk, a group of soft-bodied animals that have no bones. Oysters are called bivalve (two valve) mollusks because their shell is made up of two parts called valves.

There are several different groups of oysters. One family of oysters includes pearl oysters, which produce high-quality pearls, and wing oysters. The oysters most often eaten by human beings belong to the family known as true oysters. They are the most abundant and well-known family and are found worldwide. This article chiefly deals with true oysters.

**The body of an oyster**

**Shell.** The valves of an oyster's shell are held together by an elastic ligament at the hinge. One valve is deeper, larger, and thicker than the other. This large valve is the one that the animal normally fastens to the ocean bottom.

The elastic ligament usually keeps the valves slightly apart. A strong muscle called an adductor closes the shell. When threatened or during long periods out of the water, oysters close their valves tightly. They can live with their shell closed for several weeks.

An oyster's shell is made of a hard, chalky material called calcium carbonate. The shell is produced by a skinlike organ called the mantle, which lines the inside of the shell. The mantle takes minerals from the food the oyster eats and uses them to produce the shell. Because the mantle makes shell in cycles, periods without shell growth leave a line. The distinct shell lines can be used like the rings of a tree to estimate the age of an oyster. The shell grows as long as the oyster's body grows.

The inside of the shell is white with colored highlights. The shell of a pearl oyster is lined with a smooth, shiny substance called mother-of-pearl. A scar inside the shell indicates where the adductor muscle was attached.

Sometimes a tiny piece of grit or other foreign substance can work its way between the mantle and the shell, irritating the mantle. The irritation stimulates the production of a pearl. Shell material is evenly laid down around the particle to stop the irritation. In this way, a pearl is formed. Pearl oysters can produce high-quality pearls and are the primary source of pearls. True oysters rarely produce pearls. When they do, the pearls are dull in color, irregular in shape, and of little value.

**Body organs.** An oyster, like all bivalves, does not have a head. A pair of W-shaped gills is located beneath the mantle. The oyster uses its gills, which are covered with fine, hair-like cilia, to breathe and to trap small food particles. Water flow created by the cilia brings tiny, single-celled plantlike organisms called phytoplankton toward the gills. The cilia direct the food to the mouth. The food then moves into the oyster's stomach and final digestion takes place in the digestive gland.

The oyster's heart pumps blood to all parts of its body. A pair of kidneys removes chemical wastes.

An oyster has a simple nervous system made up of a few nerve bundles and connecting nerves. An oyster does not have eyes. However, it does have two rows of sensitive tentacles (feelers) along the mantle edge that can sense changes in light, chemicals in the water, and
water currents. Any change will cause the tentacles to contract (become smaller). In response, the adductor muscle quickly closes the shell against possible danger.

The life of an oyster

Many kinds of oysters are *hermaphroditic* (pronounced her MAH FRID ih tiv)—that is, animals with both male and female reproductive organs. Certain oysters begin their life as males but later develop into females. Other kinds alternate between male and female several times during their lives. During the female stage, various oysters can produce as many as 500 million eggs each year. Male oysters release sperm, which unite with and fertilize the eggs. In many oysters, the eggs are fertilized after the female releases them into the water. In others, the sperm enter the female’s body to fertilize the eggs.

Young. The earliest part of an oyster’s life is spent drifting in water as part of the mass of tiny organisms called *plankton*. An oyster larva develops from the fertilized egg. After about 24 hours, the larva is called a veliger (VEE uh Luh JUHR). Veligers use their cilia to move. A tiny bivalve shell is visible.

Veligers remain floating in the water for about two weeks. During this time, the animal continues to develop and forms a muscular “foot” that extends between the valves. The animal is now called a pediveliger (PAY uh VEE uh Luh JUHR). The foot is used to test different surfaces as the oyster searches for an appropriate site to settle. An oyster usually chooses a hard surface, such as a rock or the shell of another animal. It then attaches itself permanently to the surface using cement produced by its body. Most pediveligers settle with adult oysters, and together they often form crowded beds (groups) in coastal inlets.

Young oysters grow quickly. They lose their foot shortly after they settle. A month-old oyster is about the size of a pea. A year-old oyster is approximately 1 inch (2.5 centimeters) in diameter. Oysters usually grow at a rate of an inch per year for three or four years. After this time, their growth rate slows. Some North American oysters grow as large as 14 inches (36 centimeters). Most oysters live about 6 years, but some can survive more than 20 years.

Enemies. An oyster has many enemies and no defense except its shell. Diseases caused by various viruses and *protozoa* (single-celled organisms) can kill millions of oysters in a single year. Most newly hatched oysters are eaten by fish.

Once settled, even adult oysters fall prey to many animals. Starfish use their tube feet to pull at the oyster’s valves, which eventually causes the adductor muscle to weaken and the shell to open slightly. The starfish then eats the soft oyster meat. Many crabs with powerful claws and some fish with strong jaws are able to crack
the shells of small oysters. An oyster-drill snail uses a combination of glandular chemicals and filelike tongue to make a hole in an oyster's shell. Once the hole is made, the snail sucks out the oyster meat. Some birds, such as the oystercatcher, can pry an oyster's shell apart with their strong beaks.

People are the greatest enemies to oysters. They collect and eat millions of oysters each year. Overfishing and pollution have reduced the stock of oysters.

**The oyster industry**

**Oyster farming.** The popularity of oysters as food—and the threat to their natural populations—has led to the growth of oyster farming. Most oyster farms are established in shallow, quiet coastal waters where there is a firm ocean bottom. Shifting sand or mud can cover and smother oysters. Floats mark a farmed area. Oyster farmers place old shells or tiles on the bottom to act as *culch*, a surface to which the young oysters can attach themselves. Farmers often buy seed oysters to "plant" in the farming areas. Workers harvest the crop when the oysters are 2 to 4 years old and 2 to 4 inches (5 to 10 centimeters) in diameter.

Many oysters raised for market come from commercial oyster farms. Large oyster-farming centers include those along the southwest coast of France and the west coast of the United States. Oyster farmers raise and gather the shellfish along the entire coast of the United States. Louisiana, Maryland, Virginia, and Washington are the leading oyster-producing states. In Canada, the provinces of British Columbia and Prince Edward Island produce the most oysters. South Korea, Japan, the United States, and France are the leading oyster-producing countries.

**Where oysters are found**

The blue areas of the map show the parts of the world where edible oysters are found. The map includes oyster farm areas.

**Oyster harvesting** is heaviest during fall and winter in most regions. Farmers use long tongs to collect oysters in shallow waters. In deeper waters, they gather the oysters with *dredges*, which are nets attached to metal frames. The dredges are attached to a boat by a line and dragged along the bottom.

Oysters are sold either in their shells or unshelled. Workers called *shuckers* remove the shell from the oyster. A shucker forces the valves apart and then cuts the adductor muscle. The workers remove the meat from the opened shell and pack the meat for shipment.

**Oyster meat.** People eat oysters fried, broiled, *scalloped* (baked in sauce), and prepared many other ways. Oysters are rich in protein and in several minerals and vitamins. But the U.S. Food and Drug Administration advises that people with diabetes, weakened immune systems, or other medical conditions should avoid eating raw oysters. People once believed that oysters were un...
safe to eat during months without an r in their name—that is, from May to August. Scientists now know that European and North American oysters spawn (produce eggs) during summer. Oysters are less tasty when they are spawning, but they are safe to eat. Robert S. Prezant

**Scientific classification.** True oysters make up the oyster family, Ostreidae. The pearl oyster and the wing oyster belong to the family Pteriidae. An important source of pearls is *Pinctada margaritifera.*

See also Aquaculture; Mollusk; Mother-of-pearl; Pearl; Shell (Bivalves).

**Oyster plant.** See Salsify.

**Oystercatcher** is the name of a family of wading birds that live on seacoasts. The name comes from the bird’s sharp, chisel-shaped bill. The oystercatcher uses its bill to open the shells of such mollusks as mussels and oysters, and to pry limpets from rocks.

The oystercatcher uses its sharp bill to open mollusks.

The American oystercatcher lives on the Atlantic coast from the northern United States to Argentina, and on the Pacific coast from Lower California to Chile. It is smoky-brown with white underparts and a black head and neck. The American black oystercatcher lives on the Pacific coast from Alaska to Lower California. The common oystercatcher lives in Europe, Asia, Africa, and Australia. Females lay three or four eggs among pebbles.

George L. Hunt, Jr.

**Scientific classification.** Oystercatchers make up the oystercatcher family, Haematopodidae. The American oystercatcher is *Haematopus palliatus.*

**Ozark Mountains, **OH zahrk, are a range of hills extending from southern Illinois across Missouri and into Arkansas and Oklahoma. The Ozarks rise from 1,300 to 2,300 feet (457 to 701 meters) above sea level. Their highest peaks are the Boston Mountains of Arkansas. The Ozarks are part of the Ozark region, which also includes areas of flatland. The region covers about 40,000 square miles (100,000 square kilometers). The hills are covered with timber. There are many caves in the areas where the hills are made of limestone. The Ozarks of southeastern Missouri contain the most important lead mines in the United States. Mines in the Ozarks also produce iron and barite. The raising of beef cattle is the most important agricultural activity over most of the Ozark region. Farmers raise dairy cattle on the Springfield Plateau in southwest Missouri. Crops grown in the Ozark region include apples, grapes, peaches, and wheat. Tourism is a major source of income in many parts of the region. See also Missouri (Land regions). Dale Robert Martin

**Ozarks, Lake of the.** See Lake of the Ozarks.

**Ozawa, oh ZAH wahl, Seiij, SAY jee (1935- ),** is one of the outstanding orchestra conductors of his time. He established his reputation with a broad range of music, including that of many modern Japanese composers.

Charles H. Webb

**Ozick, Cynthia (1928- ),** an American author whose works consistently address fundamental questions of Jewish life. Ozick often incorporates Jewish myth and lore into modern circumstances in her novels, short stories, and essays. Her major themes include the shadow of the Holocaust over Jewish identity, the tensions between heritage and assimilation among Jewish immigrants, and the moral significance of storytelling.

Arthur M. Saltzman

**Ozone** is a gas that is present in small amounts in Earth’s atmosphere. In the troposphere (the lowest level of the atmosphere), ozone is a pollutant. It can harm plant and animal tissues, and it can damage rubber and plastic. Ozone in the stratosphere (the layer above the troposphere) blocks harmful ultraviolet rays from the sun, protecting life on Earth. Every spring in the Southern Hemisphere since the late 1970s, scientists have observed a depletion of the ozone layer over Antarctica. The region of decreased ozone is called the ozone hole.

Ozone is related to the oxygen molecules that sustain life. An oxygen molecule has two oxygen atoms and the chemical formula O₂; an ozone molecule has three oxygen atoms and the formula O₃. Pure ozone is a pale blue gas. The word ozone comes from a Greek word meaning *to smell,* reflecting ozone’s sharp, irritating odor.
Ozone occurs naturally through photochemical reactions and by electrical discharges. In photochemical reactions in the stratosphere, ultraviolet rays from the sun strike oxygen molecules, breaking each molecule into two oxygen atoms. The oxygen atoms combine with other oxygen molecules, forming ozone. Electrical discharges include lightning and sparks from motors. Such discharges can break up oxygen molecules, leading to ozone formation. Near Earth’s surface, reactions between such gases as nitrogen oxides and hydrocarbons create ozone and other ingredients of a dangerous pollutant called photochemical smog.

Commercial applications of ozone include the bleaching of pulp in paper mills and the purification of water. Manufacturers produce ozone by creating electrical discharges in a machine.

Ozone’s relative molecular mass (formerly called molecular weight)—that is, its amount of matter compared to that of the most common form of carbon—is 47.998. The German chemist Christian Friedrich Schönbein discovered ozone in 1840.

Ozone hole is a region of the atmosphere over Antarctica where a protective layer of ozone gas, a form of oxygen, becomes less concentrated every spring. The ozone layer blocks harmful ultraviolet rays from the sun, protecting life on Earth.

The ozone layer is roughly 10 miles (16 kilometers) thick. The bottom of the layer is about 6 miles (10 kilometers) above the North and South poles. When the gas becomes less concentrated, those dimensions remain about the same, but the number of ozone molecules in the layer decreases. Scientists say that the layer is depleted.

Scientists monitoring the atmosphere over Antarctica first noticed ozone depletion in the late 1970s. In 1985, researchers led by the British atmospheric scientist Joseph C. Farman showed that the ozone hole had grown since the 1960s. That is, over the years, the area of low concentrations of ozone had become larger. In addition, the ozone concentrations had become smaller.

A combination of cold weather and chemical activity creates an ozone hole every year. The cold weather creates ice surfaces on which certain chemical reactions can take place. The chemical activity begins when chemicals called chlorofluorocarbons (CFCs) break apart, creating molecules that take part in the reactions.

Most of Antarctica receives little or no sunshine from April through August, so the air becomes extremely cold. In addition, a powerful wind known as the polar jet prevents the cold air from mixing with warmer air to the north. As a result, ice clouds form in the ozone layer.

CFC molecules rise to the upper atmosphere, where ultraviolet rays break them up into smaller molecules. The smaller molecules, in turn, take part in chemical reactions on ice particles in the clouds. Those reactions create molecules that destroy ozone in the presence of sunlight.

Between August and October of each year, the number of ozone molecules in the ozone layer over Antarctica decreases by about two-thirds. The reactions that deplete the layer stop around the end of November—late spring in Antarctica. The polar jet also weakens, helping to return ozone concentration to normal.

Ozone depletion also occurs over the Arctic. However, depletion there is usually less severe because Arctic air is not as cold as Antarctic air.

CFCs do not occur in nature. Instead, they are industrially produced. They were once widely used as refrigerants and as propellants in aerosol spray cans. By international agreement, most countries have halted the production of CFCs. But an ozone hole occurs every year because of CFC molecules that remain in the atmosphere.

See also Aerosol; Chlorofluorocarbon; Ozone.

The ozone hole is a region over Antarctica where ozone becomes less concentrated every spring. These maps, based on satellite observations, show changes in the hole since 1971. Low concentrations are shown in purple and blue, and high concentrations are in orange and red. The black circle in the 1971 map represents an area for which data were unavailable.
